Cardiovascular Diseases and Conditions

Researchers at University of Edinburgh Release New Data on Hypertension (Sunlight Has Cardiovascular Benefits Independently of Vitamin D)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Cardiovascular Diseases and Conditions - Hypertension have been published. According to news reporting out of Edinburgh, United Kingdom, by NewsRx editors, the research stated, "High blood pressure (BP) is the leading risk
factor for disability adjusted life years lost globally. Epidemiological data show a correlation between increased sun exposure and reduced population BP and cardiovascular mortality."

Our news journalists obtained a quote from the research from the University of Edinburgh, "Individuals with high serum vitamin D levels are at reduced risk of hypertension, cardiovascular disease and metabolic syndrome, yet multiple trial data show that oral vitamin D supplementation has no effect on these endpoints. Sunlight is a risk factor for skin cancers, but no link has been shown with increased all-cause mortality. Cohort studies from Scandinavia show a dose-dependent fall in mortality with increased sun-seeking behaviour. Skin contains significant stores of nitrogen oxides, which can be converted to NO by UV radiation and exported to the systemic circulation. Human studies show that this pathway can cause arterial vasodilatation and reduced BP. Murine studies suggest the same mechanism may reduce metabolic syndrome. Sunlight has beneficial effects on cardiovascular risk factors independently of vitamin D. All-cause mortality should be the primary determinant of public health messages."

According to the news editors, the research concluded: "Sunlight is a risk factor for skin cancer, but sun avoidance may carry more of a cost than benefit for overall good health."

Our news journalists report that additional information may be obtained by contacting R.B. Weller, Medical Research Council Centre for Inflammation Research, University of Edinburgh, Queen's Medical Research Institute, Edinburgh, UK.

**Drugs and Therapies - Aromatase Inhibitors**

**Researchers at University of Florence Report New Data on Aromatase Inhibitors (TRPA1 Mediates Aromatase Inhibitor-Evoked Pain by the Aromatase Substrate Androstenedione)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Drugs and Therapies - Aromatase Inhibitors have been published. According to news reporting out of Florence, Italy, by NewsRx editors, research stated, "Aromatase inhibitors (AI) induce painful musculoskeletal symptoms (AIMSS), which are dependent upon the pain transducing receptor TRPA1. However, as the AI concentrations required to engage TRPA1 in mice are higher than those found in the plasma of patients, we hypothesized that additional factors may cooperate to induce AIMSS."

Our news journalists obtained a quote from the research from the University of Florence, "Here we report that the aromatase substrate androstenedione, unique among several
steroid hormones, targeted TRPA1 in peptidergic primary sensory neurons in rodent and human cells expressing the native or recombinant channel. Androstenedione dramatically lowered the concentration of letrozole required to engage TRPA1. Notably, addition of a minimal dose of androstenedione to physiologically ineffective doses of letrozole and oxidative stress byproducts produces AIMSS-like behaviors and neurogenic inflammatory responses in mice. Elevated androstenedione levels cooperated with low letrozole concentrations and inflammatory mediators were sufficient to provoke AIMSS-like behaviors.

According to the news editors, the research concluded: "The generation of such painful conditions by small quantities of simultaneously administered TRPA1 agonists justifies previous failure to identify a precise link between AIs and AIMSS, underscoring the potential of channel antagonists to treat AIMSS."

For more information on this research see: TRPA1 Mediates Aromatase Inhibitor-Evoked Pain by the Aromatase Substrate Androstenedione. *Cancer Research*, 2016;76(23):7024-7035. *Cancer Research* can be contacted at: Amer Assoc Cancer Research, 615 Chestnut St, 17TH Floor, Philadelphia, PA 19106-4404, USA. Researchers at University of Georgia Report New Data on Compartment Syndrome (Comparison of NIRS, serum biomarkers, and muscle damage in a porcine balloon compression model of acute compartment syndrome)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Diseases and Conditions - Compartment Syndrome have been presented. According to news reporting originating in Athens, Georgia, by NewsRx journalists, research stated, "Near-infrared spectroscopy (NIRS) has been shown to aid in the diagnosis of extremity acute compartment syndrome (ACS), offering continuous real-time capability to monitor perfusion in extremities. Porcine models of ACS have been developed to attempt to aid in the understanding of the development of ACS and provide better methods of diagnosing ACS."

The news reporters obtained a quote from the research from the University of
Georgia, "The objective of the present study was to assess and correlate NIRS, tibial intracompartmental pressure (TICP), tibial intracompartmental perfusion pressure (TIPP), serum markers of inflammation and muscle injury in a balloon compression model of ACS. Six swine were used. Balloon catheters were inflated below the cranial tibial muscle. Systolic, diastolic, and mean arterial pressures; compartmental pressures; and oximetry were measured before, during, and after balloon inflation/deflation. Cranial tibial muscle was collected for muscle damage scoring. Serum creatine kinase, myoglobin, tumor necrosis factor, IL-1, and IL-6 were measured. Data analysis included comparing differences in TICP, NIRS, and TIPP measurements as well as creatine kinase, myoglobin, tumor necrosis factor, IL-1, and IL-6 levels between time points. Pearson correlations were calculated for muscle degeneration and edema and NIRS. Increases in TICP and decreases in TIPP were found. Near-infrared spectroscopy detected significant changes in tissue oxygenation at all the same time points. Myoglobin significantly increased from 45.7 13.0 ng/mL (baseline) to 219.5 +/- 57.3-ng/mL (balloon deflation) and continued to increase over the duration of the study. Creatine kinase significantly increased 2 hours after balloon deflation. Cranial tibial muscle degeneration, necrosis, and edema scores were higher in the test than the control legs. Near-infrared spectroscopy of the compartment provided a reliable, sensitive measure of both an increase and decrease in TICP and TIPP in this porcine balloon model of ACS. Creatine kinase and myoglobin significantly increased following balloon removal."

According to the news reporters, the research concluded: "Significant correlations between muscle degeneration, edema, hemorrhage, and NIRS were found."

For more information on this research see: Comparison of NIRS, serum biomarkers, and muscle damage in a porcine balloon compression model of acute compartment syndrome. Journal of Trauma and Acute Care Surgery, 2016;81(5):876-881. Biomedical Engineering - Regenerative Medicine

Researchers at University of Groningen Release New Data on Regenerative Medicine (Human Salivary Gland Stem Cells Functionally Restore Radiation Damaged Salivary Glands)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Biomedical Engineering - Regenerative Medicine
have been published. According to news originating from Groningen, Netherlands, by NewsRx correspondents, research stated, "Adult stem cells are often touted as therapeutic agents in the regenerative medicine field, however data detailing both the engraftment and functional capabilities of solid tissue derived human adult epithelial stem cells is scarce. Here we show the isolation of adult human salivary gland (SG) stem/progenitor cells and demonstrate at the single cell level in vitro self-renewal and differentiation into multilineage organoids."

Financial supporters for this research include Netherlands Organisation for Health Research and Development, Netherlands Institute for Regenerative Medicine, Dutch Cancer Society.

Our news journalists obtained a quote from the research from the University of Groningen, "We also show in vivo functionality, long-term engraftment, and functional restoration in a xenotransplantation model. Indeed, transplanted human salisphere-derived cells restored saliva production and greatly improved the regenerative potential of irradiated SGs. Further selection for c-Kit expression enriched for cells with enhanced regenerative potencies. Interestingly, interaction of transplanted cells with the recipient SG may also be involved in functional recovery. Thus, we show for the first time that salispheres cultured from human SGs contain stem/progenitor cells capable of self-renewal and differentiation and rescue of saliva production."

According to the news editors, the research concluded: "Our study underpins the therapeutic promise of salisphere cell therapy for the treatment of xerostomia."

The news correspondents report that additional information may be obtained from S. Pringle, Dept. of Cell Biology, University of Groningen, University Medical Centrum Groningen, Groningen, Netherlands. Additional authors for this research include M. Maimets, M. van der Zwaag, M.A. Stokman, D. van Gosliga, E. Zwart, M.J. Witjes, G. de Haan, R. van Os and R.P Coppes.

Oncology - Acute Myeloid Leukemia

Researchers at University of Heidelberg Release New Data on Acute Myeloid Leukemia (Pretreatment d-2-hydroxyglutarate serum levels negatively impact on outcome in IDH1-mutated acute myeloid leukemia)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Oncology - Acute Myeloid Leukemia. According to news reporting out of Heidelberg, Germany, by NewsRx editors, research stated,
"Mutations in isocitrate dehydrogenases (IDHs) 1 and 2 frequently occur in acute myeloid leukemia (AML) and result in the production of the oncometabolite d-2-hydroxyglutarate (D2HG). D2HG has been shown to promote leukemogenesis even in the absence of mutated IDH, but the prognostic significance of pretreatment serum D2HG levels in patients with IDH-mutated AML is unclear."

Our news journalists obtained a quote from the research from the University of Heidelberg. "We measured D2HG serum levels in 84 patients with IDH-mutated AML treated in the prospective, randomized multicenter AML2003 trial of the German Study Alliance Leukemia. Multivariate Cox regression showed D2HG levels to negatively impact on event-free survival (EFS) as a continuous variable in the entire IDH(mut) cohort (p=0.04), with no effect on overall survival (OS). In a subgroup analysis, the negative impact of D2HG on EFS was found to be restricted to patients with mutations in IDH1 (p=0.003), adjusted for age, leukocyte count, serum lactate dehydrogenase and European LeukemiaNet risk score."

According to the news editors, the research concluded: "We thus conclude that pretreatment D2HG serum levels may yield prognostic information in patients with IDH1-mutated, but not in IDH2-mutated AML, possibly due to different subcellular localizations of IDH1 and IDH2."

For more information on this research see: Pretreatment d-2-hydroxyglutarate serum levels negatively impact on outcome in IDH1-mutated acute myeloid leukemia. Leukemia, 2015;30(4):782-8. (Nature Publishing Group - www.nature.com/; Leukemia - www.nature.com/leu/)

Our news journalists report that additional information may be obtained by contacting J. Balss, Dept. of Neuropathology, University of Heidelberg, Heidelberg, Germany. Additional authors for this research include C. Thiede, T. Bochtler, J.G. Okun, M. Saadati, A. Benner, S. Pusch, G. Ehninger, M. Schaich, A.D. Ho, A. von Deimling, A. Kramer and C.E Heilig.

Heidelberg, "Here we analyze the potential of radiomics, an emerging field of research that aims to utilize the full potential of medical imaging. A total of 4,842 quantitative MRI features were automatically extracted and analyzed from the multiparametric tumor of 172 patients (allocated to a discovery and validation set with a 2:1 ratio) with recurrent glioblastoma prior to bevacizumab treatment. Leveraging a high-throughput approach, radiomic features of patients in the discovery set were subjected to a supervised principal component (superpc) analysis to generate a prediction model for stratifying treatment outcome to antiangiogenic therapy by means of both progression-free and overall survival (PFS and OS). The superpc predictor stratified patients in the discovery set into a low or high risk group for PFS (HR = 1.60; P = 0.017) and OS (HR = 2.14; P< 0.001) and was successfully validated for patients in the validation set (HR = 1.85, P = 0.030 for PFS; HR = 2.60, P = 0.001 for OS)."

According to the news editors, the research concluded: "Our radiomic-based superpc signature emerges as a putative imaging biomarker for the identification of patients who may derive the most benefit from antiangiogenic therapy, advances the knowledge in the noninvasive characterization of brain tumors, and stresses the role of radiomics as a novel tool for improving decision support in cancer treatment at low cost."

For more information on this research see: Large-scale Radiomic Profiling of Recurrent Glioblastoma Identifies an Imaging Predictor for Stratifying Anti-Angiogenic Treatment Response.

**Gram-Positive Bacteria - Staphylococcus**

**Researchers at University of Hong Kong Report New Data on Staphylococcus (Emergence of ileS2-Carrying, Multidrug-Resistant Plasmids in Staphylococcus lugdunensis)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Gram-Positive Bacteria - Staphylococcus. According to news reporting out of Hong Kong, People's Republic of China, by NewsRx editors, research stated, "Of 137 Staphylococcus lugdunensis isolates collected from two nephrology centers in Hong Kong, 10 (7.3%) and 3 (2.2%) isolates had high-level and low-level mupirocin resistance, respectively."

Our news journalists obtained a quote from the research from the University of Hong Kong, "Isolates with high-level resistance contained the plasmid-mediated ileS2 gene, while isolates with low-level resistance contained the mutation V588F within the chromosomal ileS gene. All but one of the ileS2-positive isolates belong to the predominating clone HKU1."

According to the news editors, the research concluded: "Plasmids carrying the ileS2 gene were mosaic and also cocarry multiple other resistance determinants."

For more information on this research see: Emergence of ileS2-Carrying, Multidrug-Resistant Plasmids in Staphylococcus lugdunensis. *Antimicrobial Agents and Chemotherapy*, 2016;60(10):6411-6414. *Antimicrobial Agents and Chemotherapy* can be contacted at: Amer Soc Microbiology, 1752 N St NW, Washington, DC 20036-2904, USA. (American Society for
Researchers at University of Illinois Have Reported New Data on Salicylic Acids (Development of Poly Unsaturated Fatty Acid Derivatives of Aspirin for Inhibition of Platelet Function)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Salicylic Acids. According to news reporting out of Urbana, Illinois, by NewsRx editors, research stated, "The inhibition of platelet aggregation is key to preventing conditions such as myocardial infarction and ischemic stroke. Aspirin is the most widely used drug to inhibit platelet aggregation."

Our news journalists obtained a quote from the research from the University of Illinois, "Aspirin absorption can be improved further to increase its permeability across biologic membranes via esterification or converting the carboxylic acid to an anhydride. There are several reports indicating that omega-3 and omega-6 fatty acids such as linoleic acid, eicosapentaenoic acid (EPA), and docosahexaenoic acid (DHA) separately inhibit platelet aggregation. Herein, we synthesize anhydride conjugates of aspirin with linoleic acid, EPA, and DHA to form aspirin anhydrides that are expected to have higher permeability across cellular membranes. These aspirin-fatty acid anhydrides inhibited platelet aggregation in washed human platelets and platelet-rich plasma in a dose-dependent manner. In particular, the aspirin-DHA anhydride displayed similar effectiveness to aspirin. Platelet aggregation studies conducted in the presence of various platelet agonists indicated that the aspirin-lipid conjugates act through inhibition of the cyclooxygenase (COX)thromboxane synthase (TXAS) pathway. Hence, we performed detailed biochemical studies using purified COX-1 as well as TXAS stabilized in nanoscale lipid bilayers of nanodiscs to confirm results from the platelet aggregation studies. We show that although all of the aspirin conjugates act through the COX-TXAS pathway by inhibiting COX-1, the parent fatty acids do not act via this pathway."

According to the news editors, the research concluded: "Finally, we studied the hydrolysis of these compounds in buffer and human plasma, and we demonstrate that all of the aspirin-fatty acid conjugates hydrolyze to the parent molecules aspirin and fatty acid in a controlled manner."

For more information on this research see: Development of Poly Unsaturated Fatty Acid Derivatives of Aspirin for Inhibition of Platelet Function. *Journal of Pharmacology and Experimental Therapeutics*, 2016;359(1):134-141. *Journal of Pharmacology and Experimental Therapeutics* can be contacted at: Amer Soc Pharmacology Experimental Therapeutics, 9650 Rockville Pike, Bethesda, MD 20814-3995, USA.

Drugs and Therapies - Antibiotics

Researchers at University of Iowa Hospitals Report New Data on Antibiotics (Infection control in the operating room: is it more than a clean dish?)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Drugs and Therapies - Antibiotics. According to news reporting from Iowa City, Iowa, by NewsRx editors, the research stated, "Healthcare-associated infections (HCAIs) are driven by a complex interplay between host defenses, pathogen traits, and pathogen transmission. A better understanding of each of these factors is required to extend infection control beyond antibiotic therapy to improvements in basic preventive measures that can achieve sustained HCAI reductions."

The news correspondents obtained a quote from the research from the University of Iowa Hospitals, "The purpose of this article is to review recent advancements in our understanding of these issues for the operating room environment. The importance and implications of intraoperative bacterial transmission have been solidified, and hyper transmissible, virulent, and antibiotic resistant bacterial strains have been characterized. As a result, a best practice for improved intraoperative infection control has been delineated. Little advancement has been made in our understanding of the efficacy of higher inspired oxygen concentrations, improved postoperative glucose control, perioperative normothermia, and prophylactic antibiotic selection, timing, and dose for HCAI prevention. Recent work has led to the development of evidence-based hand hygiene, environmental cleaning, patient decolonization, and intravascular catheter design and handling improvement strategies. Evidence suggests that a best practice for postoperative infection control is a multimodal program that utilizes these interventions to target patient, provider, and environmental reservoirs in parallel."

According to the news reporters, the research concluded: "The development of novel diagnostic tools for targeted attenuation of hyper virulent, transmissible and resistant strains/strain characteristics is indicated to improve patient decolonization efforts."

For more information on this research see: Infection control in the operating room: is
Researchers at University of Jordan Target Asthma (Statins in Asthma: A Closer Look into the Pharmacological Mechanism of Action)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Lung Diseases and Conditions - Asthma. According to news reporting from Irbid, Jordan, by NewsRx journalists, research stated, "The effect of stains in asthma is mediated through targeting several signaling molecules that are involved in the development of asthma phenotype. In vitro and in vivo studies revealed that statins reduce airway smooth muscle cells proliferation and inflammatory mediators' release."

The news correspondents obtained a quote from the research from the University of Jordan, "Statins reduce chemokine release and mucus production from airway epithelial cells besides attenuating subepithelial fibrosis and eosinophils recruitment. In acute and chronic allergen driven animal models of asthma, statins reduce airway hyper-responsiveness, inflammation and remodeling. However, the effectiveness of statins in clinical trials results in contradictory conclusions based on study design and treatment protocol."

According to the news reporters, the research concluded: "Therefore, more clinical trials are needed to evaluate their role in asthma patients."

Our news journalists report that additional information may be obtained by contacting N.A. Al-Sawalha, Jordan University of Science & Technology, Coll Pharm, Irbid 22110, Jordan.

Researchers at University of Kragujevac Target Colon Cancer (Real-time monitoring of cytotoxic effects of electroporation on breast and colon cancer cell lines)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Oncology - Colon Cancer have been published. According to news reporting from Kragujevac, Serbia, by NewsRx journalists, research stated, "To study the effects of electroporation on different cell lines. Material: The effects of electroporation on human breast cancer (MDA-MB-231), human colon cancer (SW-480 and HCT-116), human fibroblast cell line (MRC-5), primary human aortic smooth muscle cells (hAoSMC) and human umbilical vein endothelial cells (HUVEC) were studied."

Financial support for this research came from Ministry of Education, Science and Technological Development of the Republic of Serbia.

The news correspondents obtained a quote from the research from the University of Kragujevac, "Real-time technology was used for cell viability monitoring. Acridine orange/ethidium bromide assay was applied for cell death type determination. A numerical model of electroporation has been proposed. Electroporation induced inhibition of cell viability on dose (voltage) dependent way. The electroporation treatment 375-437.5 V cm(-1) caused irreversible electroporation of cancer cells and reversible electroporation of healthy cells. The application of lower voltage rating (250 V cm(-1)) led to apoptosis as the predominant type of cell death, whereas the use of higher voltage (500 V cm(-1)) mainly caused necrosis. Electroporation represents a promising method in cancer treatment. Different cancer cell lines had different response to the identical electroporation treatment. Electroporation 375-437.5 V cm(-1) selectively caused permanent damage of cancer cells (SW-480), while healthy cells (MRC-5, hAoSM and HUVEC) recovered after 72 h. The type of cell death is dependent of electroporation conditions."

According to the news reporters, the research concluded: "The proposed numerical model is useful for the analysis of phenomena related to electroporation treatment."

For more information on this research see: Real-time monitoring of cytotoxic effects of electroporation on breast and colon cancer cell lines. Bioelectrochemistry, 2017;113():85-94. Drugs and Therapies - Antiretrovirals

Researchers at University of KwaZulu-Natal Have Reported New Data on Antiretrovirals (HIV-1 Drug Resistance by Ultra-Deep Sequencing Following Short Course Zidovudine, Single-Dose Nevirapine, and Single-Dose Tenofovir with Emtricitabine for ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Drugs and Therapies - Antiretrovirals have been published. According to news reporting out of Durban, South Africa, by NewsRx editors, research stated, "Antiretroviral drug resistance following pMTCT strategies remains a significant problem. With rapid advancements in next generation sequencing technologies, there is more focus on HIV drug-resistant variants of low frequency, or the so-called minority variants."

Our news journalists obtained a quote from the research from the University of KwaZulu-Natal, "In South Africa, AZT monotherapy for pMTCT, similar to World Health Organization option A, has been used since 2008. In 2010, a single dose of co-formulated TDF/FTC was included in the strategy for prevention of resistance conferred by single-dose nevirapine (sd NVP). The study was conducted in KwaZulu-Natal, South Africa, among pMTCT participants who received AZT monotherapy from 14 weeks of gestation, intrapartum AZT and sd NVP, and postpartum sd TDF/FTC. Twenty-six specimens collected at 6 weeks post-delivery were successfully sequenced using 454 ultra-deep sequencing. Non-nucleoside reverse transcriptase inhibitor (NNRTI) resistance was detected in 17 of 26 (65%) patients, 2 (7%) had Thymidine analogue mutations, and 3 (11%) had K65R. Of the 17 patients with NNRTI resistance, 11 (65%) had high-level NNRTI resistance, whereas 6 (35%) had intermediate NNRTI resistance. The levels of NNRTI resistance are much higher than would be expected, given the inclusion of antepartum AZT and postpartum TDF/FTC. This high level of NNRTI resistance could impact future NNRTI-containing treatment for a large proportion of pMTCT-exposed women."

According to the news editors, the research concluded: "The detection of Thymidine analogue mutations highlights the need to understand the clinical impact of these on AZT-containing antiretroviral treatment in women exposed to AZT monotherapy."

Our news journalists report that additional information may be obtained by contacting R. Samuel, University of KwaZulu Natal, Natl Hlth Lab Serv, Dept. of Virol, Durban, South Africa. Additional authors for this research include M.N. Julian, R. Paredes, R. Parboosing, P. Moodley, L. Singh, A. Naidoo and M. Gordon.

Keywords for this news article include: Durban, South Africa, Africa, Nucleoside Reverse Transcriptase Inhibitors (NRTIs), Viral Sexually Transmitted Diseases and Conditions,
Researchers at University of Lille Report New Data on Ventricular Fibrillation (Long-term outcome of implantable cardioverter-defibrillator implantation in secondary prevention of sudden cardiac death)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Heart Disorders and Diseases - Ventricular Fibrillation have been presented. According to news reporting originating in Lille, France, by NewsRx journalists, research stated, "Background.-Little is known about the long-term outcomes of patients who receive an implantable cardioverter-defibrillator (ICD) for purely secondary prevention indications. Aims.-To assess the rates and predictors of appropriate therapies over a very long-term followup period in this population."

The news reporters obtained a quote from the research from the University of Lille, "Methods.-Between June 2003 and August 2006, 239 consecutive patients with structural left ventricular disease and a secondary prophylaxis indication for ICD therapy (survivors of life threatening ventricular tachyarrhythmias) were prospectively enrolled. An extended follow-up of these patients was carried out. The primary endpoint was the occurrence of appropriate device therapy. Secondary endpoints were all-cause death, electrical storm and inappropriate therapy. Results.-The study population consisted of 239 patients (90% men; mean age 64 +/- 12 years; 72% ischaemic cardiomyopathy; left ventricular ejection fraction 37 +/- 12%). During a median follow-up of 7.8 (3.5-9.3) years, appropriate device therapy occurred in 139 (58.2%) patients. Death occurred in 141 patients (59%), electrical storm in 73 (30.5%) and inappropriate therapy in 42 (17.6%). Multivariable analysis identified patients whose presenting arrhythmia was ventricular fibrillation as being less likely to require appropriate device therapy than those whose presenting arrhythmia was ventricular tachycardia (sub-hazard ratio 0.62, 95% confidence interval 0.40-0.97; P=6.04). Independent predictors of all-cause death were age at implantation (P < 0.0001), wide QRS complexes (P = 0.024), creatinine concentration (P=0.0002) and B-type natriuretic peptide at implantation (P=0.0001). Conclusion.- Secondary prevention ICD recipients exhibit a high risk of appropriate device therapy and death over prolonged follow-up."

According to the news reporters, the research concluded: "Patients who presented initially with ventricular fibrillation were less likely to require the delivery of appropriate device therapy."

For more information on this research see: Long-term outcome of implantable cardioverter-defibrillator implantation in secondary prevention of sudden cardiac death. Archives of Cardiovascular Diseases, 2016;109(10):517-526. Archives of Cardiovascular Diseases can be contacted at: Elsevier Masson, Via Paleocapa 7, 20121 Milano, Italy. Researchers at University of Ljubljana Detail Findings in Breast Cancer (gKlotho is a novel marker and cell survival factor in a subset of triple negative breast cancers)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Oncology - Breast Cancer is now available. According to news reporting originating in Ljubljana, Slovenia, by NewsRx journalists, research stated, "Over the last decade, breast cancer mortality has declined. However, triple negative breast cancer (TNBC) remains a challenging problem mostly due to early recurrence and lack of molecularly driven treatments."

The news reporters obtained a quote from the research from the University of Ljubljana, "There is a critical need to identify subgroups of TNBC with common molecular features that can be therapeutically targeted. Here we show that in contrast to Klotho and bKlotho, the third member of the Klotho protein family, gKlotho, is overexpressed in more than 60% of TNBCs and correlates with poorer disease progression. Furthermore, we find that gKlotho is expressed in a subset of TNBC cell lines promoting cell growth. Importantly, we demonstrate that in these cells gKlotho is necessary for cell survival and that its depletion leads to constitutive ERK activation, cell cycle arrest and apoptosis. Interestingly, we observe increased oxidative stress in gKlotho-depleted cells suggesting that gKlotho enables cancer cells to cope with an oxidative environment and that cells become dependent on its expression to maintain this survival advantage."

According to the news reporters, the research concluded: "These findings indicate that gKlotho might be a potential marker for patients that would benefit from treatments that alter oxidative stress and constitutes a novel drug target for a subset of TN breast cancers."

For more information on this research see: gKlotho is a novel marker and cell survival factor in a subset of triple negative breast cancers. Oncotarget, 2016;7(3):2611-28.

Researchers at University of Manchester Target Anterior Pituitary Hormones (Effect of summer daylight exposure and genetic background on growth in growth hormone-deficient children)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Hormones - Anterior Pituitary Hormones. According to news reporting originating from Manchester, United Kingdom, by NewsRx correspondents, research stated, "The response to growth hormone in humans is dependent on phenotypic, genetic and environmental factors. The present study in children with growth hormone deficiency (GHD) collected worldwide characterised gene-environment interactions on growth response to recombinant human growth hormone (r-hGH)."

Our news editors obtained a quote from the research from the University of Manchester, "Growth responses in children are linked to latitude, and we found that a correlate of latitude, summer daylight exposure (SDE), was a key environmental factor related to growth response to r-hGH. In turn growth response was determined by an interaction between both SDE and genes known to affect growth response to r-hGH. In addition, analysis of associated networks of gene expression implicated a role for circadian clock pathways and specifically the developmental transcription factor NANOG."

According to the news editors, the research concluded: "This work provides the first observation of gene-environment interactions in children treated with r-hGH."

The news editors report that additional information may be obtained by contacting C. De Leonibus, Institute of Human Development, University of Manchester and Royal Manchester Children's Hospital, Central Manchester University Hospitals NHS Foundation Trust, Manchester Academic Health Science Centre, Manchester, UK. Additional authors for this research include P. Chatelain, C. Knight, P. Clayton and A. Stevens.

Researchers at University of Massachusetts Report New Data on Oncology Nursing (Advantages and Limitations of Wearable Activity Trackers: Considerations for Patients and Clinicians)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Nursing - Oncology Nursing.

According to news reporting out of Amherst, Massachusetts, by NewsRx editors, research stated, "Exercise, light physical activity, and decreased sedentary time all have been associated with health benefits following cancer diagnoses. Commercially available wearable activity trackers may help patients monitor and self-manage their behaviors to achieve these benefits."

Our news journalists obtained a quote from the research from the University of Massachusetts, "This article highlights some advantages and limitations clinicians should be aware of when discussing the use of activity trackers with cancer survivors. Limited research has assessed the accuracy of commercially available activity trackers compared to research-grade devices. Because most devices use confidential, proprietary algorithms to convert accelerometry data to meaningful output like total steps, assessing whether these algorithms account for differences in gait abnormalities, functional limitations, and different body morphologies can be difficult. Quantification of sedentary behaviors and light physical activities present additional challenges. The global market for activity trackers is growing, which presents clinicians with a tremendous opportunity to incorporate these devices into clinical practice as tools to promote activity."

According to the news editors, the research concluded: "This article highlights important considerations about tracker accuracy and usage by cancer survivors."

For more information on this research see: Advantages and Limitations of Wearable Activity Trackers: Considerations for Patients and Clinicians. Clinical Journal of Oncology Nursing, 2016;20(6):606-610. Clinical Journal of Oncology Nursing can be contacted at: Oncology Nursing Soc, 125 Enterprise Dr, Pittsburgh, PA 15275, USA.

Our news journalists report that additional information may be obtained by contacting R.K. Walker, University of Massachusetts, Coll Nursing, Amherst, MA 01003, United States. Additional authors for this research include A.M. Hickey and P.S. Freedson.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1188/16.CJON.606-610. This DOI is a link to an online electronic document that is either free or for purchase.

Researchers at University of Medicine and Dentistry of New Jersey (UMDNJ) Have Reported New Data on Arteriovenous Fistula
(Endovascular Management of Spinal Dural Arteriovenous Fistulas)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Cardiovascular Diseases and Conditions - Arteriovenous Fistula is now available. According to news reporting from Newark, New Jersey, by NewsRx journalists, research stated, "Spinal vascular malformations, although rare, cause devastating disease. These malformations are commonly categorized as follows: spinal arteriovenous malformations (AVMs), dural arteriovenous fistulas (DAVFs), spinal hemangiomas, cavernous angiomas, and aneurysms."

The news correspondents obtained a quote from the research from the University of Medicine and Dentistry of New Jersey (UMDNJ), "Spinal DAVFs (SDAVFs), or type 1 spinal AVMs, occur most frequently, representing similar to 60 to 80% of vascular malformations of the spinal cord. While previously microsurgical treatment was considered the gold standard in the treatment of SDAVFs, recent advancements in technology-advancements of magnetic resonance imaging as a screening examination, contrast-enhanced magnetic resonance angiography, multidetector computed tomography as preangiographic evaluations, digital subtraction angiography, diagnostic catheters, and embolization materials-have made endovascular treatment a possible option."

According to the news reporters, the research concluded: "We review the treatment of SDAVFs, primarily discussing the endovascular management of these lesions."

Our news journalists report that additional information may be obtained by contacting C.J. Prestigiacomo, Rutgers New Jersey Med Sch, Dept. of Neurol & Neurosci, Newark, NJ, United States. Additional authors for this research include D.R. Hansberry, A. Meleis, B.A. Lieber, C.D. Gandhi and C.J. Prestigiacomo.

Researchers at University of Medicine and Dentistry of New Jersey (UMDNJ) Report New Data on Dermatology (Basal cell naevus syndrome: an update on genetics and treatment)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Health and Medicine - Dermatology. According to news reporting out of Newark, New Jersey, by NewsRx editors, research stated, "Basal cell naevus syndrome is an autosomal dominant disorder that stems from mutations in multiple genes, most commonly patched 1 (PTCH1). The classic triad of symptoms consists of basal cell carcinomas, jaw keratocysts and cerebral calcifications, although there are many other systemic manifestations."

Our news journalists obtained a quote from the research from the University of Medicine and Dentistry of New Jersey (UMDNJ), "Because of the broad range of symptoms and development of several types of tumours, early diagnosis and close monitoring are essential to preserve quality of life. Targeting treatment is often difficult because of tumor prevalence. Newer inhibitors of the hedgehog signalling pathway and proteins involved in proliferative growth have shown therapeutic promise. In addition, preventive medications are being devised."

According to the news editors, the research concluded: "We propose a method for determining appropriate treatment for cutaneous tumours."

Our news journalists report that additional information may be obtained by contacting A.M. John, Dept. of Dermatology, Rutgers New Jersey Medical School, Newark, NJ, 07103, United States.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1111/bjd.14206. This DOI is a link to an online electronic document that is either free or for purchase.

Researchers at University of Melbourne Discuss Findings in Heart Failure (Comorbidity of atrial fibrillation and heart failure)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Heart Disorders and Diseases - Heart Failure. According to news originating from Melbourne, Australia, by NewsRx correspondents, research stated, "Atrial fibrillation (AF) and heart failure (HF) are evolving epidemics, together responsible for substantial human suffering and health-care expenditure. Ageing, improved cardiovascular survival, and epidemiological transition form the basis for their increasing global
Our news journalists obtained a quote from the research from the University of Melbourne, "Although we now have a clear picture of how HF promotes AF, gaps remain in our knowledge of how AF exacerbates or even causes HF, and how the development of HF affects the outcome of patients with AF. New data regarding HF with preserved ejection fraction and its unique relationship with AF suggest a possible role for AF in its aetiology, possibly as a trigger for ventricular fibrosis. Deciding on optimal treatment strategies for patients with both AF and HF is increasingly difficult, given that results from trials of pharmacological rhythm control are arguably obsolete in the age of catheter ablation. Restoring sinus rhythm by catheter ablation seems successful in the medium term and improves HF symptoms, functional capacity, and left ventricular function. Long-term studies to examine the effect on rates of stroke and death are ongoing."

According to the news editors, the research concluded: "Guidelines continue to evolve to keep pace with this rapidly changing field."

For more information on this research see: Comorbidity of atrial fibrillation and heart failure. Nature Reviews Cardiology, 2015;13(3):131-47. (Nature Publishing Group - www.nature.com/nature.com/nature.com/nature.com/nrcardio/)

The news correspondents report that additional information may be obtained from L.H. Ling, Dept. of Cardiovascular Medicine, University of Melbourne and The Alfred Hospital, Royal Parade, Melbourne, Victoria 3181, Australia. Additional authors for this research include P.M. Kistler, J.M. Kalman, R.J. Schilling and R.J Hunter.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1038/nrcardio.2015.191. This DOI is a link to an online electronic document that is either free or for purchase.

Researchers at University of Miami Have Reported New Data on Anesthesia (Case report: management of differential diagnosis and treatment of severe anaphylaxis in the setting of spinal anesthesia)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Anesthesia. According to news reporting originating in Miami, Florida, by NewsRx journalists, research stated, "The purpose of this case report is to educate fellow anesthesiologists of a complicated differential diagnosis for sudden cardiovascular collapse after spinal anesthesia. We report a case where anaphylaxis occurred while under spinal anesthesia and resulted in difficult resuscitation."

The news reporters obtained a quote from the research from the University of Miami, "A 58-year-old woman undergoing bilateral knee replacements under spinal anesthesia experienced sudden seizure and cardiovascular collapse from acute anaphylactic shock while administering a cephalosporin. Local anesthetic toxicity, high spinal, and anaphylaxis were..."
considered due to overlapping of symptoms. Successful resuscitation required prolonged advanced cardiac life support with substantially larger doses of epinephrine. Anaphylactic shock under spinal anesthesia is an acute and life-threatening complication, worsened by the spinal-induced sympathectomy, and aggressive resuscitation is warranted. Despite the presence of overlapping symptoms of differential diagnoses, rapid identification of the cause of cardiovascular collapse is crucial given that resuscitation treatment modalities may conflict.

According to the news reporters, the research concluded: "Timing of antibiotic administration should be adjusted for spinal anesthesia cases to allow time to detect possible anaphylaxis."

Our news correspondents report that additional information may be obtained by contacting B.M. Osman, University of Miami, Miller Sch Med, Dept. of Anesthesiol, Miami, FL 33136, United States. Additional authors for this research include J.M. Maga and S.M. Baquero.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1016/j.jclinane.2016.07.009. This DOI is a link to an online electronic document that is either free or for purchase.

Acetanilides

Researchers at University of Miami Release New Data on Acetanilides (Understanding the large solubility of lidocaine in 1-n-butyl-3-methylimidazolium based ionic liquids using molecular simulation)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Acetanilides is the subject of a report. According to news reporting from Oxford, Ohio, by NewsRx journalists, research stated, "Room temperature ionic liquids have been proposed as replacement solvents in a wide range of industrial separation processes. Here, we focus on the use of ionic liquids as solvents for the pharmaceutical compound lidocaine."

Financial supporters for this research include Miami University College of Engineering and Computing, Miami University Committee on Faculty Research.

The news correspondents obtained a quote from the research from the University of Miami, "We show that the solubility of lidocaine in seven common 1-n-butyl-3-methylimidazolium based ionic liquids is greatly enhanced relative to water. The predicted solubility is greatest in [BMIM](+)[CH3CO[2](-), which we find results from favorable hydrogen bonding between the lidocaine amine hydrogen and the [CH3CO][2](-) oxygen, favorable electrostatic interactions between the lidocaine amide oxygen with the [BMIM](+)}
aromatic ring hydrogens, while lidocaine does not interfere with the association of [BMIM](+) with [CH3CO[2]](-).

According to the news reporters, the research concluded: "Additionally, by removing functional groups from the lidocaine scaffold while maintaining the important amide group, we found that as the van der Waals volume increases, solubility in [BMIM](+)[CH3CO[2]](-) relative to water increases."

For more information on this research see: Understanding the large solubility of lidocaine in 1-n-butyl-3-methylimidazolium based ionic liquids using molecular simulation. The Journal of Chemical Physics, 2016;144(8):084501.

Our news journalists report that additional information may be obtained by contacting R.T. Ley, Dept. of Chemical, Paper and Biomedical Engineering, Miami University, Oxford, Ohio 45056, United States.

Age-Related Macular Degeneration

Researchers at University of Miami Target Age-Related Macular Degeneration (Heritability of Choroidal Thickness in the Amish)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Age-Related Macular Degeneration. According to news reporting out of Miami, Florida, by NewsRx editors, research stated, "To evaluate the heritability of choroidal thickness and its relationship to age-related macular degeneration (AMD). Cohort study. Six hundred eighty-nine individuals from Amish families with early or intermediate AMD."

Our news journalists obtained a quote from the research from the University of Miami, “Ocular coherence tomography was used to quantify choroidal thickness, and fundus photography was used to classify eyes into categories using a modified Clinical Age-Related Maculopathy Staging (CARMs) system. Repeatability and heritability of choroidal thickness and its phenotypic and genetic correlations with the AMD phenotype (CARMs category) were estimated using a generalized linear mixed model (GLMM) approach that accounted for relatedness, repeated measures (left and right eyes), and the effects of age, gender, and refraction. Heritability of choroidal thickness and its phenotypic and genetic correlation with the AMD phenotype (CARMs category). Phenotypic correlation between choroidal thickness and CARMs category was moderate (Spearman's rank correlation, rs = -0.24; n = 1313 eyes) and significant (GLMM posterior mean, -4.27; 95% credible interval [CI], -7.88 to -0.79; P = 0.02) after controlling for relatedness, age, gender, and refraction. Eyes with advanced AMD had thinner choroids than eyes without AMD (posterior mean, -73.8; 95% CI, -94.7 to -54.6; P<0.001; n = 1178 eyes). Choroidal thickness was highly repeatable within individuals (repeatability, 0.78; 95% CI, 0.68 to 0.89) and moderately heritable (heritability, 0.40; 95% CI,
0.14 to 0.51), but did not show significant genetic correlation with CARMS category, although the effect size was moderate (genetic correlation, -0.18; 95% CI, -0.49 to 0.16). Choroidal thickness also varied with age, gender, and refraction. The CARMS category showed moderate heritability (heritability, 0.49; 95% CI, 0.26 to 0.72). We quantify the heritability of choroidal thickness for the first time, highlighting aheritable, quantitative trait that is measurable in all individuals regardless of AMD affection status, and moderately phenotypically correlated with AMD severity. Choroidal thickness therefore may capture variation not captured by the CARMS system. However, because the genetic correlation between choroidal thickness and AMD severity was not significant in our data set, genes associated with the 2 traits may not overlap substantially."

According to the news editors, the research concluded: "Future studies should therefore test for genetic variation associated with choroidal thickness to determine the overlap in genetic basis with AMD."

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1016/j.ophtha.2016.09.001. This DOI is a link to an online electronic document that is either free or for purchase.

**Meniere’s Disease**

**Researchers at University of Michigan Target Meniere's Disease (SLC44A2 single nucleotide polymorphisms, isoforms, and expression: Association with severity of Meniere’s disease?)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Meniere's disease. According to news reporting originating from Ann Arbor, Michigan, by NewsRx correspondents, research stated, "SLC44A2 was discovered as the target of an antibody that causes hearing loss. Knockout mice develop age related hearing loss, loss of sensory cells and spiral ganglion neurons."

Financial support for this research came from NIH.

Our news editors obtained a quote from the research from the University of Michigan, "SLC44A2 has polymorphic sites implicated in human disease. Transfusion related acute lung injury (TRALI) is linked to rs2288904 and genome wide association studies link rs2288904 and rs9797861 to venous thromboembolism (VTE), coronary artery disease and
stroke. Here we report linkage disequilibrium of rs2288904 with rs3087969 and the association of these SLC44A2 SNPs with Meniere's disease severity. Tissue-specific isoform expression differences suggest that the N-terminal domain is linked to different functions in different cell types. Heterozygosity at rs2288904 CGA/CAA and rs3087969 GAT/GAC showed a trend for association with intractable Meniere's disease compared to less severe disease and to controls."

According to the news editors, the research concluded: "The association of SLC44A2 SNPs with VTE suggests that thrombi affecting cochlear vessels could be a factor in Meniere's disease."

For more information on this research see: SLC44A2 single nucleotide polymorphisms, isoforms, and expression: Association with severity of Meniere's disease? Genomics, 2016;108(5-6):201-208. Genomics can be contacted at: Academic Press Inc Elsevier Science, 525 B St, Ste 1900, San Diego, CA 92101-4495, USA. (Elsevier - www.elsevier.com; Genomics - www.journals.elsevier.com/genomics/)

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1016/j.ygeno.2016.11.002. This DOI is a link to an online electronic document that is either free or for purchase.

Hormones - Estradiol Congeners

Researchers at University of Milan Have Reported New Data on Estradiol Congeners (Hormonal influence on the effect of mirabegron treatment for overactive bladder)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Hormones - Estradiol Congeners are presented in a new report. According to news originating from Milan, Italy, by NewsRx correspondents, research stated, "The aim of this study was to evaluate if levels of gonadotropic and sex steroidal hormones influence the efficacy of mirabegron in the treatment of overactive bladder. We included 58 female participants who received treatment with mirabegron 50 mg once daily and provided a blood sample for hormone profiling before treatment was initiated."

Our news journalists obtained a quote from the research from the University of Milan, "Serum hormone concentrations for estradiol, progesterone, testosterone, FSH, LH, TSH, and T4 were analyzed. Urinary Distress Inventory (UDI), (overactive bladder domain: UDIOAB), and the short form Pelvic Floor Impact Questionnaire (PFIQ-7) were used to assess subjective outcomes. There were significant overall improvements in UDI, UDIOAB, and the
PFIQ from baseline to the 2 months of follow-up (P = 0.001, 0.001, and 0.008, respectively). The magnitude of the mean difference of improvements was similar between pre-and postmenopausal women. Estrogen levels were nonsignificantly lower in participants who experienced an improvement in UDI and UDIOAB at 2 months of follow-up as compared with those that did not (P = 0.7). There were no other clinically relevant differences in hormone levels in relation to improvements in UDI, UDIOAB, or PFIQ. In logistic regression analysis there were no associations between UDIOAB outcomes and age, previous use of anticholinergic drugs, parity, menopause, and local estrogen treatment. Estradiol, gonadotropic hormones, thyroid hormones, and testosterone levels did not influence the clinical effects of mirabegron in women with overactive bladder.

According to the news editors, the research concluded: "Menopause status should not be a determinant for mirabegron treatment."

The news correspondents report that additional information may be obtained from D. Altman, Univ Milano Bicocca, Dept. of Stat & Quantitat Methods, Milan, Italy. Additional authors for this research include C. Elmer, K.E. Andersson and D. Altman.

Keywords for this news article include: Milan, Italy, Europe, Estradiol Congeners, Gonadal Hormones, Women's Health, Endocrinology, Estrogens, University of Milan.

Anions

Researchers at University of Milan Release New Data on Anions (Iron citrate reduces high phosphate-induced vascular calcification by inhibiting apoptosis)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Anions is the subject of a report. According to news reporting originating from Milan, Italy, by NewsRx correspondents, research stated, "High phosphate-induced vascular calcification (VC) and iron deficiency-induced anemia are two major contributors of cardiovascular morbidity and mortality in patients affected by chronic kidney disease (CKD). Since phosphate (Pi) control and iron replacement are common therapies in CKD, the aim of our study was to investigate the effect of iron on high Pi-induced VC in rat vascular smooth muscle cells (VSMCs)."

Our news editors obtained a quote from the research from the University of Milan, "We treated VSMCs with 5 mM Pi and iron citrate (Fe3+) to evaluate Ca deposition by Alizarin Red destaining, DNA fragmentation by ELISA, gene expression by RT-PCR and protein expression by Western blot. Pretreatment with Fe3+ prevents high Pi-induced calcium (Ca) deposition concentration-dependently, with 90.1% inhibition at 50 mu M (0.716 +/- 0.04 vs. 0.071 +/- 0.01, OD/mg protein; Pi vs. Pi + Fe3+, p< 0.01). We found that 50 mM Fe3+ completely prevents high Pi-induced apoptosis measured as DNA fragmentation (1.51 +/- 0.08 vs. 1.03 +/- 0.06, Pi vs. Pi + Fe3+: p< 0.01), through the prevention of the downregulation of the
According to the news editors, the research concluded: "Iron citrate inhibits high Pi-induced Ca deposition by prevention of apoptosis, induction of autophagy, and partially affecting osteoblastic differentiation."

Science

Researchers at University of Montreal Target Science (Social status alters immune regulation and response to infection in macaques)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Science have been published. According to news originating from Montreal, Canada, by NewsRx correspondents, research stated, "Social status is one of the strongest predictors of human disease risk and mortality, and it also influences Darwinian fitness in social mammals more generally. To understand the biological basis of these effects, we combined genomics with a social status manipulation in female rhesus macaques to investigate how status alters immune function."

Our news journalists obtained a quote from the research from the University of Montreal, "We demonstrate causal but largely plastic social status effects on immune cell proportions, cell type-specific gene expression levels, and the gene expression response to immune challenge. Further, we identify specific transcription factor signaling pathways that explain these differences, including low-status-associated polarization of the Toll-like receptor 4 signaling pathway toward a proinflammatory response."

According to the news editors, the research concluded: "Our findings provide insight into the direct biological effects of social inequality on immune function, thus improving our understanding of social gradients in health."

The news correspondents report that additional information may be obtained from
Researchers at University of Naples Federico II Have Reported New Data on Squamous Cell Carcinoma (Neck dissection versus "watchful-waiting" in early squamous cell carcinoma of the tongue our experience on 127 cases)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Oncology - Squamous Cell Carcinoma. According to news reporting originating from Naples, Italy, by NewsRx correspondents, research stated, "Early oral squamous cell carcinoma (EOSCC) represents about 90% of the oral cancers especially in older males. The etiology is multifactorial, strongly related to tobacco and alcohol abuse, but also infective agents, Human papillomaviruses (HPV16-18), genetic factors and pre-neoplastic lesions seem to be implicated."

Our news editors obtained a quote from the research from the University of Naples Federico II, "There is no consensus in the literature for the treatment of early squamous cell carcinoma of the tongue (stages I-II); both an elective neck dissection policy and a watchful-waiting policy have their proponents in the different centers. The records of 127 patients with EOSCC of the tongue treated in our Department between 2007 and 2011, with cN0 neck staging, who underwent resection of the primary tumor with or without elective neck dissection, were reviewed. We divided the patients into two groups, in Group 1 the 66 patients who received an elective neck dissection 30 days later from the primary surgery have been included, and in Group 2 the 61 patients undergoing 'watchful waiting' observation for the development of nodal metastases have been collected. Statistical calculations were performed using Chi-square and t student test. A significant difference was found between the two groups as concerns tumor stage and pathologic tumor classification (p < 0.001). No significant differences were present between the two groups as concerns mean follow up (P = 0.2), relapse rate (p = 0.3) and relapse-free survival time (p = 0.2). In T1 stage tumors with depth of infiltration <= 4 mm, or low grade (G1-G2), the 'watchful waiting' strategy for cervical metastases is appropriate, given the low regional recurrence rate (15%) and overall survival of 100%.

According to the news editors, the research concluded: "In case of T2 lesions with depth of infiltration => 4 mm or high grade (G3) we prefer to perform the elective neck dissection, with 13% of local recurrence and 100% of survival at 6 years."

For more information on this research see: Neck dissection versus "watchful-waiting" in early squamous cell carcinoma of the tongue our experience on 127 cases. Surgical

The news editors report that additional information may be obtained by contacting P. Bonavolonta, University of Naples Federico II, Dept. of Maxillofacial Surg, Naples, Italy. Additional authors for this research include P. Bonavolonta, F. Maglitto, M. Friscia, G. Iaconetta and L. Califano.

Keywords for this news article include: Naples, Italy, Europe, Otorhinolaryngologic Surgical Procedures, Squamous Cell Carcinoma, Neck Dissection, Carcinomas, Oncology, Genetics, Surgery, University of Naples Federico II.

Immune System Diseases and Conditions - HIV/AIDS

Researchers at University of New South Wales Target HIV/AIDS (Circulating microRNAs in Sera Correlate with Soluble Biomarkers of Immune Activation but Do Not Predict Mortality in ART Treated Individuals with HIV-1 Infection: A Case Control Study)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Immune System Diseases and Conditions - HIV/AIDS have been presented. According to news reporting originating in Sydney, Australia, by NewsRx journalists, research stated, "The use of anti-retroviral therapy (ART) has dramatically reduced HIV-1 associated morbidity and mortality. However, HIV-1 infected individuals have increased rates of morbidity and mortality compared to the non-HIV-1 infected population and this appears to be related to end-organ diseases collectively referred to as Serious Non-AIDS Events (SNAEs)."

The news reporters obtained a quote from the research from the University of New South Wales, "Circulating miRNAs are reported as promising biomarkers for a number of human disease conditions including those that constitute SNAEs. Our study sought to investigate the potential of selected miRNAs in predicting mortality in HIV-1 infected ART treated individuals. A set of miRNAs was chosen based on published associations with human disease conditions that constitute SNAEs. This case: control study compared 126 cases (individuals who died whilst on therapy), and 247 matched controls (individuals who remained alive). Cases and controls were ART treated participants of two pivotal HIV-1 trials. The relative abundance of each miRNA in serum was measured, by RTqPCR. Associations with mortality (all-cause, cardiovascular and malignancy) were assessed by logistic regression analysis. Correlations between miRNAs and CD4+ T cell count, hs-CRP, IL-6 and D-dimer were also assessed. None of the selected miRNAs was associated with all-cause, cardiovascular or malignancy mortality. The levels of three miRNAs (miRs -21, -122 and -200a) correlated with IL-6 while miR-21 also correlated with D-dimer. Additionally, the abundance of miRs -31, -150 and -223, correlated with baseline CD4+ T cell count while the same three miRNAs plus miR-145 correlated with nadir CD4+ T cell count. No associations with mortality were found with any circulating miRNA studied."

According to the news reporters, the research concluded: "These results cast doubt onto the effectiveness of circulating miRNA as early predictors of mortality or the major underlying diseases that contribute to mortality in participants treated for HIV-1 infection."
For more information on this research see: Circulating microRNAs in Sera Correlate with Soluble Biomarkers of Immune Activation but Do Not Predict Mortality in ART Treated Individuals with HIV-1 Infection: A Case Control Study. Plos One, 2015;10(10):e0139981. (Public Library of Science - www.plos.org; Plos One - www.plosone.org)

Nutritional and Metabolic Diseases and Conditions ...

Researchers at University of Niigata Target Type 2 Diabetes [The fruit of Acanthopanax senticosus (Rupr. et Maxim.) Harms improves insulin resistance and hepatic lipid accumulation by modulation of liver adenosine monophosphate-activated protein ...]

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Nutritional and Metabolic Diseases and Conditions - Type 2 Diabetes. According to news originating from Niigata, Japan, by NewsRx correspondents, research stated, "Obesity-associated insulin resistance is a major risk factor for most metabolic diseases, including dyslipidemia and type 2 diabetes. Acanthopanax senticosus (Rupr. et Maxim.) Harms (Goka) root has been used in traditional Chinese medicine for treatment of diabetes and other conditions; however, little is known about the effects of Goka fruit (GF). Goka fruit is rich in anthocyanin, which has beneficial effects on obesity and insulin resistance via activation of adenosine monophosphate activated protein kinase (AMPK)."

Our news journalists obtained a quote from the research from the University of Niigata, "We hypothesized that GF can improve obesity-associated insulin resistance. The aim of the present study was to investigate whether GF improves insulin resistance in high-fat diet (HFD) induced obese mice. High-fat diet mice treated with GF (500 and 1000 mg/kg) for 12 weeks showed an improved glucose tolerance and insulin sensitivity, as well as reduced plasma insulin and liver lipid accumulation. Moreover, GF administration to HFD mice resulted in down-regulation of fatty acid synthase expression and up-regulation of cholesterol 7-alpha-hydroxylase expression in the liver. Notably, AMPK phosphorylation in the liver increased after GF administration."

According to the news editors, the research concluded: "In summary, GF supplementation improved obesity-associated insulin resistance and hepatic lipid accumulation
through modulation of AMPK activity and lipid metabolism associated gene expression."

The news correspondents report that additional information may be obtained from H. Nishida, Niigata University of Pharmacy & Applied Life Sciences, Fac Appl Life Sci, Niigata, Niigata 9568603, Japan. Additional authors for this research include M. Nishida, M. Saito, A. Tanabe, T. Eitsuka, S.H. Yuan, N. Ikekawa and H. Nishida.

**Stroke**

**Researchers at University of North Carolina Report New Data on Stroke (Variants of Rab GTPase-Effector Binding Protein-2 Cause Variation in the Collateral Circulation and Severity of Stroke)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Stroke are discussed in a new report. According to news reporting from Chapel Hill, North Carolina, by NewsRx journalists, research stated, "The extent (number and diameter) of collateral vessels varies widely and is a major determinant, along with arteriogenesis (collateral remodeling), of variation in severity of tissue injury after large artery occlusion. Differences in genetic background underlie the majority of the variation in collateral extent in mice, through alterations in collaterogenesis (embryonic collateral formation)."

The news correspondents obtained a quote from the research from the University of North Carolina, "In brain and other tissues, approximate to 80% of the variation in collateral extent among different mouse strains has been linked to a region on chromosome 7. We recently used congenic (CNG) fine mapping of C57BL/6 (B6, high extent) and BALB/cByJ (BC, low extent) mice to narrow the region to a 737 Kb locus, Dce1. Herein, we report the causal gene. We used additional CNG mapping and knockout mice to narrow the number of candidate genes. Subsequent inspection identified a nonsynonymous single nucleotide polymorphism between B6 and BC within Rabep2 (rs33084087). We then created B6 mice with the BC single nucleotide polymorphism at this locus plus 3 other lines for predicted alteration or knockout of Rabep2 using gene editing. The single amino acid change caused by rs33084087 accounted for the difference in collateral extent and infarct volume between B6 and BC mice attributable to Dce1. Mechanistically, variants of Rabep2 altered collaterogenesis during embryogenesis but had no
effect on angiogenesis examined in vivo and in vitro. Rabep2 deficiency altered endosome trafficking known to be involved in VEGF-A -> VEGFR2 signaling required for collaterogenesis."

According to the news reporters, the research concluded: "Naturally occurring variants of Rabep2 are major determinants of variation in collateral extent and stroke severity in mice."

For more information on this research see: Variants of Rab GTPase-Effector Binding Protein-2 Cause Variation in the Collateral Circulation and Severity of Stroke. Stroke, 2016;47(12):3022-3031. Stroke can be contacted at: Lippincott Williams & Wilkins, Two Commerce Sq, 2001 Market St, Philadelphia, PA 19103, USA. Drugs and Therapies - Drug Delivery Systems

Researchers at University of North Carolina Target Drug Delivery Systems (Tumor Microenvironment-Mediated Construction and Deconstruction of Extracellular Drug-Delivery Depots)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Drugs and Therapies - Drug Delivery Systems have been presented. According to news originating from Raleigh, North Carolina, by NewsRx correspondents, research stated, "Protein therapy has been considered the most direct and safe approach to treat cancer. Targeting delivery of extracellularly active protein without internalization barriers, such as membrane permeation and endosome escape, is efficient and holds vast promise for anticancer treatment."

Financial support for this research came from National Center for Advancing Translational Sciences.

Our news journalists obtained a quote from the research from the University of North Carolina, "Herein, we describe a 'transformable' core-shell based nanocarrier (designated CS-NG), which can enzymatically assemble into microsized extracellular depots at the tumor site with assistance of hyaluronidase (HAase), an overexpressed enzyme at the tumor microenvironment. Equipped with an acid-degradable modality, the resulting CS-NG can substantially release combinational anticancer drugs-tumor necrosis factor (TNF)-related apoptosis inducing ligand (TRAIL) and antiangiogenic cilenitide toward the membrane of cancer cells and endothelial cells at the acidic tumor microenvironment, respectively."

According to the news editors, the research concluded: "Enhanced cytotoxicity on MDA-MB-231 cells and improved antitumor efficacy were observed using CS-NG, which was attributed to the inhibition of cellular internalization and prolonged retention time in vivo."

The news correspondents report that additional information may be obtained from Q. Hu, Joint Dept. of Biomedical Engineering, University of North Carolina at Chapel Hill and North Carolina State University, Raleigh, North Carolina 27695, United States. Additional authors for this research include W. Sun, Y. Lu, H.N. Bomba, Y. Ye, T. Jiang, A.J. Isaacson and Z. Gu.

**Drugs and Therapies - Cancer Therapy**

**Researchers at University of Oklahoma Report New Data on Cancer Therapy (Label-Free Real-Time Microarray Imaging of Cancer Protein-Protein Interactions and Their Inhibition by Small Molecules)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Drugs and Therapies - Cancer Therapy are presented in a new report. According to news reporting originating from Oklahoma City, Oklahoma, by NewsRx correspondents, research stated, "A rapid optical microarray imaging approach for anticancer drug screening at specific cancer protein-protein interface targets with binding kinetics and validation by a mass sensor is reported for the first time. Surface plasmon resonance imager (SPRi) demonstrated a 3.5-fold greater specificity for interactions between murine double minute 2 protein (MDM2) and wild-type p53 over a nonspecific p53 mutant in a real-time microfluidic analysis."

Financial support for this research came from College of Arts and Sciences, Oklahoma State University.

Our news editors obtained a quote from the research from the University of Oklahoma, "Significant percentage reflectivity changes (D%R) in the SPRi signals and molecular-level mass changes were detected for both the MDM2-p53 interaction and its inhibition by a small-molecule Nutlin-3 drug analogue known for its anticancer property. We additionally demonstrate that synthetic, inexpensive binding domains of interacting cancer proteins are sufficient to screen anticancer drugs by an array-based SPRi technique with excellent specificity and sensitivity."

According to the news editors, the research concluded: "This imaging array, combined with a mass sensor, can be used to study quantitatively any protein-protein interaction and screen for small molecules with binding and potency evaluations."

For more information on this research see: Label-Free Real-Time Microarray Imaging of Cancer Protein-Protein Interactions and Their Inhibition by Small Molecules. *Analytical Chemistry*, 2016;88(6):3130-5. (American Chemical Society - www.acs.org;
Analytical Chemistry - www.pubs.acs.org/journal/ancham)

The news editors report that additional information may be obtained by contacting D.M. Benbrook, Dept. of Obstetrics and Gynecology, University of Oklahoma Health Sciences Center, Oklahoma City, Oklahoma 73104, United States. Additional authors for this research include Z.H. Al Mubarak, B. Zhang, M. Akinwale, A. Pathiranage, J. Deng, K.D. Berlin, D.M. Benbrook and S. Krishnan.

Drugs and Therapies - Alimentary Pharmacology and…

Researchers at University of Orebro Report New Data on Alimentary Pharmacology and Therapeutics (Consensus report: faecal microbiota transfer - clinical applications and procedures)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Drugs and Therapies - Alimentary Pharmacology and Therapeutics are presented in a new report. According to news reporting originating from Orebro, Sweden, by NewsRx correspondents, research stated, "Faecal microbiota transplantation or transfer (FMT) aims at replacing or reinforcing the gut microbiota of a patient with the microbiota from a healthy donor. Not many controlled or randomised studies have been published evaluating the use of FMT for other diseases than Clostridium difficile infection, making it difficult for clinicians to decide on a suitable indication."

Financial support for this research came from Seres Therapeutics.

Our news editors obtained a quote from the research from the University of Orebro, "To provide an expert consensus on current clinical indications, applications and methodological aspects of FMT. Well-acknowledged experts from various countries in Europe have contributed to this article. After literature review, consensus has been achieved by repetitive circulation of the statements and the full manuscript among all authors with intermittent adaptation to comments (using a modified Delphi process). Levels of evidence and agreement were rated according to the GRADE system. Consensus was defined a priori as agreement by at least 75% of the authors. Key recommendations include the use of FMT in recurrent C. difficile infection characterised by at least two previous standard treatments without persistent cure, as well as its consideration in severe and severe-complicated C. difficile infection as an alternative to total colectomy in case of early failure of antimicrobial therapy. FMT in inflammatory bowel diseases (IBD), irritable bowel syndrome (IBS) and metabolic syndrome should only be performed in research settings. Faecal microbiota transplantation or transfer is a promising treatment for a variety of diseases in which the intestinal microbiota is disturbed."

According to the news editors, the research concluded: "For indications other than C. difficile infection, more evidence is needed before more concrete recommendations can be
made."

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1111/apt.13868. This DOI is a link to an online electronic document that is either free or for purchase.

Keywords for this news article include: Örebro, Sweden, Europe, Alimentary Pharmacology and Therapeutics, Drugs and Therapies, University of Örebro.

**Transport Vesicles**

**Researchers at University of Oslo Report New Data on Transport Vesicles (Bidirectional traffic between the Golgi and the endosomes - machineries and regulation)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Transport Vesicles is now available. According to news originating from Oslo, Norway, by NewsRx correspondents, research stated, "The bidirectional transport between the Golgi complex and the endocytic pathway has to be finely regulated in order to ensure the proper delivery of newly synthetized lysosomal enzymes and the return of sorting receptors from degradative compartments. The high complexity of these routes has led to experimental difficulties in properly dissecting and separating the different pathways."

Our news journalists obtained a quote from the research from the University of Oslo, "As a consequence, several models have been proposed during the past decades. However, recent advances in our understanding of endosomal dynamics have helped to unify these different views. We provide here an overview of the current insights into the transport routes between Golgi and endosomes in mammalian cells. The focus of the Commentary is on the key molecules involved in the trafficking pathways between these intracellular compartments, such as Rab proteins and sorting receptors, and their regulation."

According to the news editors, the research concluded: "A proper understanding of the bidirectional traffic between the Golgi complex and the endolysosomal system is of uttermost importance, as several studies have demonstrated that mutations in the factors involved in these transport pathways result in various pathologies, in particular lysosome-associated diseases and diverse neurological disorders, such as Alzheimer's and Parkinson's disease."

For more information on this research see: Bidirectional traffic between the Golgi
Researchers at University of Otago Report New Data on Epilepsy (Alterations In Ampa Receptor Subunit Expression In Cortical Inhibitory Interneurons In The Epileptic Stargazer Mutant Mouse)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Central Nervous System Diseases and Conditions - Epilepsy are discussed in a new report. According to news originating from Dunedin, New Zealand, by NewsRx correspondents, research stated, "Absence seizures arise from disturbances within the corticothalamocortical network, however the precise cellular and molecular mechanisms underlying seizure generation arising from different genetic backgrounds are not fully understood. While recent experimental evidence suggests that changes in inhibitory microcircuits in the cortex may contribute to generation of the hallmark spike-wave discharges, it is still unclear if altered cortical inhibition is a result of interneuron dysfunction due to compromised glutamatergic excitation and/or changes in cortical interneuron number."

Our news journalists obtained a quote from the research from the University of Otago, "The stargazer mouse model of absence epilepsy presents with a genetic deficit in stargazin, which is predominantly expressed in cortical parvalbumin-positive (PV+) interneurons, and involved in the trafficking of glutamatergic AMPA receptors. Hence, in this study we examine changes in (1) the subunit-specific expression of AMPA receptors which could potentially result in a loss of excitation onto cortical PV+ interneurons, and (2) PV+ neuron density that could additionally impair cortical inhibition. Using Western blot analysis we found subunit-specific alterations in AMPA receptor expression in the stargazer somatosensory cortex. Further analysis using confocal fluorescence microscopy revealed that although there are no changes in cortical PV+ interneuron number, there is a predominant loss of GluA1 and 4 containing AMPA receptors in PV+ neurons in stargazers compared to non-epileptic controls. Taken together, these data suggest that the loss of AMPA receptors in PV+ neurons could impair their feed-forward inhibitory output, ultimately altering cortical network oscillations, and contribute to seizure generation in stargazers."

According to the news editors, the research concluded: "As such the feed forward inhibitory interneurons could be potential targets for future therapeutic intervention for some absence epilepsy patients."

For more information on this research see: Alterations In Ampa Receptor Subunit Expression In Cortical Inhibitory Interneurons In The Epileptic Stargazer Mutant Mouse. Neuroscience, 2016;339():124-138. Neuroscience can be contacted at: Pergamon-Elsevier Science Ltd, The Boulevard, Langford Lane, Kidlington, Oxford OX5 1GB, England.
Researchers at University of Ottawa Report New Data on Suicide (Child abuse and the prevalence of suicide attempts among those reporting suicide ideation)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Suicide have been published. According to news reporting out of Ottawa, Canada, by NewsRx editors, research stated, "Victims of child abuse may be at increased risk of acting on suicide ideation, although this has not been empirically tested. We estimated the risk of suicide attempts associated with child abuse among individuals who reported suicide ideation."

Our news journalists obtained a quote from the research from the University of Ottawa, "Secondary analysis of data from the population-based Canadian Community Health Survey Mental Health (n = 828). This population-based survey included various structured questionnaires, including the Composite International Diagnostic Interview to assess mental illness and suicidal thoughts and behaviours. Approximately 80 % of those who attempted suicide had a history of child abuse. Poor mental health, financial difficulties, poor coping skills, and reporting a suicide plan were also associated with an increased prevalence of attempting suicide; adjusted for these factors, child abuse was associated with a 1.77-fold increased prevalence (95 % CI 0.93, 3.36) of suicide attempts. Most individuals who attempt suicide experience child abuse, and worse health and social functioning."

According to the news editors, the research concluded: "Adopting a life-course perspective to understand trajectories of suicide risk factors may inform prevention and treatment."

Our news journalists report that additional information may be obtained by
Researchers at University of Oxford Report Findings in Clinical Trials and Studies (Targeting the CCL2-CCR2 signaling axis in cancer metastasis)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Clinical Research - Clinical Trials and Studies are discussed in a new report. According to news reporting out of Oxford, United Kingdom, by NewsRx editors, research stated, "The CCL2-CCR2 signaling axis has generated increasing interest in recent years due to its association with the progression of cancer. Although first described as a chemotactic molecule with physiological roles in regulating inflammation, recent studies have revealed a pro-tumorigenic function for CCL2 in favoring cancer development and subsequent metastasis."

Our news journalists obtained a quote from the research from the University of Oxford, "CCL2 binds the cognate receptor CCR2, and together this signaling pair has been shown to have multiple pro-tumorigenic roles, from mediating tumor growth and angiogenesis to recruiting and usurping host stromal cells to support tumor progression. The importance of CCL2-CCR2 signaling has been further championed by the establishment of clinical trials targeting this signaling pair in solid and metastatic cancers. Here we review the roles of CCL2-CCR2 signaling in the development and progression of cancer metastasis."

According to the news editors, the research concluded: "We further evaluate the outcome of several clinical trials targeting either CCL2 or CCR2, and discuss the prospects and challenges of manipulating CCL2-CCR2 interaction as a potential approach for combating metastatic disease."

For more information on this research see: Targeting the CCL2-CCR2 signaling axis in cancer metastasis. Oncotarget, 2016;7(19):28697-710.

Our news journalists report that additional information may be obtained by contacting S.Y. Lim, CRUK, MRC Oxford Institute for Radiation Oncology, University of Oxford, Oxford, UK. Additional authors for this research include A.E. Yuzhalin, A.N. Gordon-Weeks and R.J Muschel.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.18632/oncotarget.7376. This DOI is a link to an online electronic document that is either free or for purchase.

Keywords for this news article include: Oxford, Europe, Cancer, Oncology, United Kingdom, Article Review, Clinical Research, Clinical Trials and Studies.
Researchers at University of Padova Describe Findings in Atrial Fibrillation (A Randomized Trial of Pharmacogenetic Warfarin Dosing in Na?ve Patients with Non-Valvular Atrial Fibrillation)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Heart Disorders and Diseases - Atrial Fibrillation. According to news originating from Padova, Italy, by NewsRx correspondents, research stated, "Genotype-guided warfarin dosing have been proposed to improve patient's management. This study is aimed to determine whether a CYP2C9-VKORC1-CYP4F2-based pharmacogenetic algorithm is superior to a standard, clinically adopted, pharmacodynamic method."

Our news journalists obtained a quote from the research from the University of Padova, "Two-hundred na?ve patients with non-valvular atrial fibrillation were randomized to trial arms and 180 completed the study. No significant differences were found in the number of out-of-range INRs (INR <2.0 or >3.0) (p=0.79) and in the mean percentage of time spent in the therapeutic range (TTR) after 19 days in the pharmacogenetic (51.9%) and in the control arm (53.2%, p=0.71). The percentage of time spent at INR >4.0 was significantly lower in the pharmacogenetic (0.7%) than in the control arm (1.8%) (p=0.02)."

According to the news editors, the research concluded: "Genotype-guided warfarin dosing is not superior in overall anticoagulation control when compared to accurate clinical standard of care."

For more information on this research see: A Randomized Trial of Pharmacogenetic Warfarin Dosing in Na?ve Patients with Non-Valvular Atrial Fibrillation. Plos One, 2015;10 (12):e0145318. (Public Library of Science - www.plos.org; Plos One - www.plosone.org)

The news correspondents report that additional information may be obtained from V. Pengo, Dept. of Cardiac, Thoracic and Vascular Sciences University of Padova, Padova, Italy. Additional authors for this research include C.F. Zambon, P. Fogar, A. Padoan, G. Nante, M. Pelloso, S. Moz, A.C. Frigo, F. Groppa, D. Bozzato, E. Tiso, E. Gnatta, G. Denas, S. Padayattil Jose, R. Padrini, D. Basso and M. Plebani.

Researchers at University of Padua Target Imino Acids [Natural Deep Eutectic Solvents (NADES) as a Tool for Bioavailability Improvement: Pharmacokinetics of Rutin Dissolved in Proline/Glycine after Oral Administration in Rats: Possible ...]

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Imino Acids are presented in a new report. According to news reporting from Padua, Italy, by NewsRx journalists, research stated, "There is a need for innovation in plant-derived pharmaceuticals, food supplements and nutraceutical products regarding the use of more eco-sustainable solvents for their extraction. Furthermore, the poor oral bioavailability of several phytochemicals with health promoting effects stimulates the research in the field of pharmaceutical formulations."

The news correspondents obtained a quote from the research from the University of Padua, "Natural Deep Eutectic Solvents (NADES) are formed by natural compounds, and can be considered as future solvents being especially useful for the preparation of nutraceuticals and food-grade extracts. In this paper various NADES were prepared using sugars, amino acids and organic acids. Rutin (quercetin-3-O-alpha-L-rhamnopyranosyl-(1 -> 6))-beta-D-glucopyranose) was used as a model compound to study NADES. Moreover, the effect of various eutectic mixtures on rutin's water solubility was studied. Proline/glutamic acid (2:1) and proline/choline chloride (1:1) mixtures have a solubility comparable to ethanol. The proline/glutamic acid (2:1) eutectic containing rutin was used in a pharmacokinetic study in Balb/c mice while bioavailability was compared to oral dosing of water suspension. Plasmatic levels of rutin were measured by HPLC-MS/MS showing increased levels and longer period of rutin permanence in plasma of NADES treated animals."

According to the news reporters, the research concluded: "This paper reports the possible use of non-toxic NADES for pharmaceutical and nutraceutical preparations."

For more information on this research see: Natural Deep Eutectic Solvents (NADES) as a Tool for Bioavailability Improvement: Pharmacokinetics of Rutin Dissolved in Proline/Glycine after Oral Administration in Rats: Possible Application in Nutraceuticals. Researchers at University of Palermo Target Osteosarcomas (The secreted protein acidic and rich in cysteine is a critical mediator of cell death program induced by WIN/TRAIL combined treatment in osteosarcoma cells)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Oncology - Osteosarcomas is now available. According to news reporting out of Palermo, Italy, by NewsRx editors, research stated, "Secreted protein acidic and rich in cysteine (SPARC) is a multi-functional protein which modulates cell-cell and cell-matrix interactions. In cancer cells, SPARC behaves as a tumor promoter in a number of tumors, but it can also act as a tumor suppressor factor."

Our news journalists obtained a quote from the research from the University of Palermo, "Our previous results showed that the synthetic cannabinoid WIN55,212-2 (WIN), a potent cannabinoid receptor agonist, is able to sensitize osteosarcoma MG63 cells to TNF-related apoptosis-inducing ligand (TRAIL)-induced apoptosis which is accompanied with endoplasmic reticulum (ER)-stress induction and the increase in autophagic markers. In the present investigation, we studied the role of SPARC in WIN/TRAIL-induced apoptosis demonstrating that WIN increased the level of SPARC protein and mRNA in a time-dependent manner. This event was functional to WIN/TRAIL-dependent apoptosis as demonstrated by RNA interfering analysis which indicated that SPARC-silenced cells were less sensitive to cytotoxic effects induced by the combined treatment. Our experiments also demonstrate that SPARC interacts with caspase-8 thus probably favoring its translocation to plasma membrane and the activation of extrinsic apoptotic pathway."

According to the news editors, the research concluded: "To the best of our knowledge, our results are the first to show that WIN-dependent increase in the level of SPARC plays a critical role in sensitizing osteosarcoma cells to TRAIL action."

For more information on this research see: The secreted protein acidic and rich in cysteine is a critical mediator of cell death program induced by WIN/TRAIL combined treatment in osteosarcoma cells. International Journal of Oncology, 2015;48(3):1039-44.

Our news journalists report that additional information may be obtained by contacting A. Notaro, Dept. of Biological, Chemical and Pharmaceutical Sciences and Technologies, Laboratory of Biochemistry, University of Palermo, Polyclinic, Palermo 90128, Italy. Researchers at University of Paris Report Findings in Oncology (Genetic polymorphisms associated with increased risk of developing chronic myelogenous leukemia)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Oncology. According to news reporting from Paris, France, by NewsRx journalists, research stated, "Little is known about inherited factors associated with the risk of developing chronic myelogenous leukemia (CML). We used a dedicated DNA chip containing 16,561 single nucleotide polymorphisms (SNPs) covering 1,916 candidate genes to analyze 437 CML patients and 1,144 healthy control individuals."

The news correspondents obtained a quote from the research from the University of Paris, "Single SNP association analysis identified 139 SNPs that passed multiple comparisons (1% false discovery rate). The HDAC9, AVEN, SEMA3C, IKBKB, GSTA3, RIPK1 and FGF2 genes were each represented by three SNPs, the PSM family by four SNPs and the SLC15A1 gene by six. Haplotype analysis showed that certain combinations of rare alleles of these genes increased the risk of developing CML by more than two or three-fold. A classification tree model identified five SNPs belonging to the genes PSMB10, TNFRSF10D, PSMB2, PPARD and CYP26B1, which were associated with CML predisposition. A CML-risk-allele score was created using these five SNPs. This score was accurate for discriminating CML status (AUC: 0.61, 95%CI: 0.58-0.64). Interestingly, the score was associated with age at diagnosis and the average number of risk alleles was significantly higher in younger patients. The risk-allele score showed the same distribution in the general population (HapMap CEU samples) as in our control individuals and was associated with differential gene expression patterns of two genes (VAPA and TDRKH)."

According to the news reporters, the research concluded: "We describe haplotypes and a genetic score that are significantly associated with a predisposition to develop CML. The SNPs identified will also serve to drive fundamental research on the putative role of these genes in CML development."

For more information on this research see: Genetic polymorphisms associated with increased risk of developing chronic myelogenous leukemia. Oncotarget, 2015;6(34):36269-77.

Prothrombin

Researchers at University of Paris Report Findings in Prothrombin
(Repeat liver retransplantation: rationale and outcomes)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Prothrombin. According to news reporting from Villejuif, France, by NewsRx journalists, research stated, "Liver retransplantation remains the only option for recurrent graft failure. The aim of our study is to identify predictive factors involved in patients and graft survival for patients undergoing repeat retransplantation (RRT)."

The news correspondents obtained a quote from the research from the University of Paris, "From January 1985 to December 2012, 2940 liver transplantations were performed in 2477 patients at Paul Brousse Hospital, Villejuif, France. All patients who underwent third, fourth, and fifth transplantation were included in the study and retrospectively analyzed. In the univariate analysis, the factors that were associated with 90-d patient post-operative survival were pre-operative vasopressors support, pre-operative extra hepatic sepsis, primary non-function (PNF) as indication of RRT, recipient's model of end stage liver disease (MELD), urgent RRT, creatinine value at RRT, and prothrombin ratio. The multivariate logistic regression confirmed the role of systemic septic status (OR=12.8, p=0.01) and vasopressor drug support (OR=4.7, p=0.05) as predictors of post-operative mortality. In the univariate analysis, the factors that were associated with patient 10 yr long-term survival (were vasopressor support, systemic septic patient, PNF as indication of RRT, RRT occurred between 1985 and 1999, recipient's MELD, creatinine value at RRT, and prothrombin ratio. The multivariate logistic regression confirmed the role of systemic septic patient (OR=6.4, p=0.03) and the RRT between 1985 and 1999 (OR=3.6, p=0.05) as predictors of long-term mortality. RRT represent a valid alternative in selected patients. Selection should be oriented on patients needing third transplant without extra hepatic sepsis and vasoactive drug support at moment of RRT."

According to the news reporters, the research concluded: "If necessary, fourth and fifth RRT could be performed with a decision made on case-by-case basis, despite a high post-operative mortality."

Our news journalists report that additional information may be obtained by contacting R. Memeo, Centre Hepato-biliaire, Paul Brousse Hospital, Universite Paris Sud, Villejuif, France. Additional authors for this research include A. Laurenzi, G. Pittau, S. Sanchez-Cabus, E. Vibert, R. Adam, D. Azoulay, A.S. Cunha, P. Ichai, F. Saliba, D. Samuel, D. Cherqui and D. Castaing.

Researchers at University of Parma Release New Data on Clinical Research in Anesthesia (Perineural catheter infection: a systematic review of the literature)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Clinical Research - Clinical Research in Anesthesia have been published. According to news reporting originating in Parma, Italy, by NewsRx journalists, research stated, "Perineural catheter infection is a rare but potentially dramatic complication of continuous peripheral nerve block. Different risk factors have been identified and the incidence of infection is increased in trauma victims, intensive care unit patients, immunodeficient individuals, and diabetic patients."

The news reporters obtained a quote from the research from the University of Parma, "Also, postoperative hyperglycemia, the absence of antibiotic prophylaxis, and catheter lasting more than 48 hours seem to be associated with a greater risk of infection. Skin disinfection and a strict aseptic technique during catheter placement are fundamental. The use of micropore filters, antiseptic dressings, catheter tunneling, and aseptic preparation of the infused drug has all been hypothesized to reduce infection rate, but the existing evidence is conflicting. Infection is a rare complication of continuous peripheral nerve blocks. Severe and even fatal cases have been reported, even if morbidity is generally very low."

According to the news reporters, the research concluded: "The identification of high risk patients and adoption of preventive measures might reduce the incidence of this complication."

Our news correspondents report that additional information may be obtained by contacting D. Nicolotti, Parma Univ Hosp, Dept. of Anesthesia Intens Care & Pain Med 2, I-43126 Parma, Italy. Additional authors for this research include E. Iotti, G. Fanelli and C. Compagnone.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1016/j.jclinane.2016.07.025. This DOI is a link to an online electronic document that is either free or for purchase.

Researchers at University of Pennsylvania Report New Data on Type 2 Diabetes (Roles of Fe-S proteins: from cofactor synthesis to iron homeostasis to protein synthesis)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Nutritional and Metabolic Diseases and Conditions - Type 2 Diabetes is now available. According to news originating from Philadelphia, Pennsylvania, by NewsRx correspondents, research stated, "Fe-S cluster assembly is an essential process for all cells. Impairment of Fe-S cluster assembly creates diseases in diverse and surprising ways."

Our news journalists obtained a quote from the research from the University of Pennsylvania, "In one scenario, the loss of function of lipoic acid synthase, an enzyme with Fe-S cluster cofactor in mitochondria, impairs activity of various lipoamide-dependent enzymes with drastic consequences for metabolism. In a second scenario, the heme biosynthetic pathway in red cell precursors is specifically targeted, and iron homeostasis is perturbed, but lipoic acid synthesis is unaffected. In a third scenario, tRNA modifications arising from action of the cysteine desulfurase and/or Fe-S cluster proteins are lost, which may lead to impaired protein synthesis."

According to the news editors, the research concluded: "These defects can then result in cancer, neurologic dysfunction or type 2 diabetes."

The news correspondents report that additional information may be obtained from A. Dancis, University of Pennsylvania, Perelman Sch Med, Dept. of Med, Div Hematol Oncol, Philadelphia, PA 19104, United States.

Keywords for this news article include: Philadelphia, Pennsylvania, United States, North and Central America, Nutritional and Metabolic Diseases and Conditions, Non-Insulin Dependent Diabetes Mellitus, Proteomics, Genetics, Risk and Prevention, Protein Synthesis, Medical Devices, Type 2 Diabetes, University of Pennsylvania.

Drugs and Therapies - Health-System Pharmacy

Researchers at University of Pittsburgh Have Reported New Data on Health-System Pharmacy (Educational strategies to enable expansion of pharmacogenomics-based care)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Drugs and Therapies - Health-System Pharmacy is now available. According to news originating from Pittsburgh, Pennsylvania, by NewsRx
correspondents, research stated, "The current state of pharmacogenomics education for pharmacy students and practitioners is discussed, and resources and strategies to address persistent challenges in this area are reviewed. Consensus-based pharmacist competencies and guidelines have been published to guide pharmacogenomics knowledge attainment and application in clinical practice."

Our news journalists obtained a quote from the research from the University of Pittsburgh, "Pharmacogenomics education is integrated into various pharmacy school courses and, increasingly, into Pharm.D. curricula in the form of required standalone courses. Continuing education programs and a limited number of postgraduate training opportunities are available to practicing pharmacists. For colleges and schools of pharmacy, identifying the optimal structure and content of pharmacogenomics education remains a challenge; insufficient numbers of faculty members with pharmacogenomics expertise and the inadequate availability of practice settings for experiential education are other limiting factors. Strategies for overcoming those challenges include providing early exposure to pharmacogenomics through foundational courses and incorporating pharmacogenomics into practice-based therapeutics courses and introductory and advanced pharmacy practice experiences. For practitioner education, online resources, clinical decision support-based tools, and certificate programs can be used to supplement structured postgraduate training in pharmacogenomics. Recently published data indicate successful use of 'shared curricula' and participatory education models involving opportunities for learners to undergo personal genomic testing. The pharmacy profession has taken a leadership role in expanding student and practitioner education to meet the demand for increased pharmacist involvement in precision medicine initiatives."

According to the news editors, the research concluded: "Effective approaches to teaching pharmacogenomics knowledge and driving its appropriate application in clinical practice are increasingly available."

For more information on this research see: Educational strategies to enable expansion of pharmacogenomics-based care. American Journal of Health-System Pharmacy, 2016;73(23):1986-1998. American Journal of Health-System Pharmacy can be contacted at: Amer Soc Health-System Pharmacists, 7272 Wisconsin Ave, Bethesda, MD 20814, USA.

The news correspondents report that additional information may be obtained from P.E. Empey, University of Pittsburgh, Inst Precis Med, Pittsburgh, PA 15260, United States. Additional authors for this research include C.L. Aquilante, S. Johnson, D.F. Kisor and P.E. Empey.

Researchers at University of Pittsburgh Release New Data on Ovarian Cancer (Cancer and treatment-related symptoms are associated with mobility disability in women with ovarian cancer: A cross-sectional study)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Oncology - Ovarian Cancer are discussed in a new report. According to news reporting from Pittsburgh, Pennsylvania, by NewsRx journalists, research stated, "To examine the prevalence of symptom-related mobility disability and identify specific symptoms and other factors associated with mobility disability among a national sample of ovarian cancer (OC) survivors. Descriptive, correlational secondary analysis of a National Ovarian Cancer Coalition mailed survey of women with a history of OC (n = 713)."

The news correspondents obtained a quote from the research from the University of Pittsburgh, "We used the Symptom Representation Questionnaire (SRQ), the MD Anderson Symptom Inventory (MDASI) Interference Scale, and medical and demographic information to determine prevalence of symptom-related mobility disability. We constructed a multiple linear regression model to determine the relative contributions of specific symptoms and other factors to mobility disability. A majority of the sample (60.0%) reported symptom-related mobility disability. Independent predictors included: > one comorbidity (3 = 0.097, p = 0.006), active OC = 0.111, p = 0.037), abdominal bloating (3 = 0.072, p = 0.045), numbness/tingling (3 = 0.134, p < 0.001), and pain (3 = 0.194, p < 0.001). The model explained 41.5% of the variance in symptom related mobility disability (R2 = 0.415). Unsurprisingly, age (3 = 0.028, p = 0.412) and current chemotherapy (3 = 0.107, p = 0.118) were not significant predictors. Symptom-related mobility disability is common among women with OC and is associated with medical comorbidities, abdominal bloating, fatigue, lack of appetite, numbness/tingling, and pain."

According to the news reporters, the research concluded: "Longitudinal research should clarify the relationship of these symptoms to mobility disability and determine whether effective symptom management minimizes disability."

For more information on this research see: Cancer and treatment-related symptoms are associated with mobility disability in women with ovarian cancer: A cross-sectional study. Gynecologic Oncology, 2016;143(3):578-583. Gynecologic Oncology can be contacted at: Academic Press Inc Elsevier Science, 525 B St, Ste 1900, San Diego, CA 92101-4495, USA. Researchers at University of Primorska Target Ischemia (Chronic exposure to zinc oxide nanoparticles increases ischemic-reperfusion injuries in isolated rat hearts)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Ischemia. According to news reporting originating in Koper, Slovenia, by NewsRx journalists, research stated, "The use of zinc oxide nanoparticles (ZnO NPs) in numerous products is increasing, although possible negative implications of their long-term consumption are not known yet. Our aim was to evaluate the chronic, 6-week oral exposure to two different concentrations of ZnO NPs on isolated rat hearts exposed to ischemic-reperfusion injury and on small intestine morphology."

The news reporters obtained a quote from the research from the University of Primorska, "Wistar rats of both sexes (n = 18) were randomly divided into three groups: (1) 4 mg/kg ZnO NPs, (2) 40 mg/kg ZnO NPs, and (3) control. After 6 weeks of treatment, the hearts were isolated, the left ventricular pressure (LVP), the coronary flow (CF), the duration of arrhythmias and the lactate dehydrogenase release rate (LDH) were measured. A histological investigation of the small intestine was performed. Chronic exposure to ZnO NPs acted cardiotoxic dose-dependently. ZnO NPs in dosage 40 mg/kg maximally decreased LVP (3.3-fold) and CF (2.5-fold) and increased the duration of ventricular tachycardia (all P< 0.01) compared to control, whereas ZnO NPs in dosage 4 mg/kg acted less cardiotoxic. Goblet cells in the small intestine epithelium of rats, treated with 40 mg ZnO NPs/kg, were enlarged, swollen and numerous, the intestinal epithelium width was increased. Unexpectedly, ZnO NPs in both dosages significantly decreased LDH. A 6-week oral exposure to ZnO NPs dose-dependently increased heart injuries and caused irritation of the intestinal mucosa."

According to the news reporters, the research concluded: "A prolonged exposure to ZnO NPs might cause functional damage to the heart even with exposures to the recommended daily doses, which should be tested in future studies."

Our news correspondents report that additional information may be obtained by contacting G. Drevensek, Univ Primorska, Fac Math Nat Sci & Informat Technol, Koper 6000, Slovenia. Additional authors for this research include D. Drobne, T. Romih, L.B. Mali, I. Marin, M. Lunder and G. Drevensek.

Researchers at University of Queensland Target Membrane Glycoproteins (Xenopus borealis as an alternative source of oocytes for biophysical and pharmacological studies of neuronal ion channels)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Membrane Proteins - Membrane Glycoproteins have been published. According to news reporting originating in St. Lucia, Australia, by NewsRx journalists, research stated, "For the past 30 years, oocytes from Xenopus laevis have been extensively used to express and characterise ion channels in an easily controlled environment. Here we report the first use of oocytes from the closely related species Xenopus borealis as an alternative expression system for neuronal ion channels."

The news reporters obtained a quote from the research from the University of Queensland, "Using the two-electrode voltage-clamp technique, we show that a wide variety of voltage-and ligand-gated ion channels have the same channel properties and pharmacological profiles when expressed in either X. laevis or X. borealis oocytes. Potential advantages of the X. borealis oocytes include a smaller endogenous chloride current and the ability to produce more intense fluorescence signals when studied with voltage-clamp fluorometry. Scanning electron microscopy revealed a difference in vitelline membrane structure between the two species, which may be related to the discrepancy in fluorescence signals observed."

According to the news reporters, the research concluded: "We demonstrate that X. borealis oocytes are a viable heterologous system for expression of neuronal ion channels with some potential advantages over X. laevis oocytes for certain applications."

For more information on this research see: Xenopus borealis as an alternative source of oocytes for biophysical and pharmacological studies of neuronal ion channels. Scientific Reports, 2015;5():14763. (Nature Publishing Group - www.nature.com/; Scientific Reports - www.nature.com/srep/)

Our news correspondents report that additional information may be obtained by contacting B. Cristofori-Armstrong, Institute for Molecular Bioscience, The University of Queensland, St Lucia, QLD 4072, Australia. Additional authors for this research include M.S. Soh, S. Talwar, D.L. Brown, J.D. Griffin, Z. Dekan, J.L. Stow, G.F. King, J.W. Lynch and L.D Rash.

**Heart Disorders and Diseases - Heart Failure**

**Researchers at University of Sao Paulo Have Reported New Data on Heart Failure (Aerobic Exercise and Pharmacological Therapies for Skeletal Myopathy in Heart Failure: Similarities and Differences)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Heart Disorders and Diseases - Heart Failure. According to news reporting originating from Sao Paulo, Brazil, by NewsRx correspondents, research stated, "Skeletal myopathy has been identified as a major comorbidity of heart failure (HF) affecting up to 20% of ambulatory patients leading to shortness of breath, early fatigue, and exercise intolerance. Neurohumoral blockade, through the inhibition of renin angiotensin aldosterone system (RAS) and b-adrenergic receptor blockade (b-blockers), is a mandatory pharmacological therapy of HF since it reduces symptoms, mortality, and sudden death."

Funders for this research include National Natural Science Foundation of China, Conselho Nacional de Desenvolvimento Cientifico e Tecnologico.

Our news editors obtained a quote from the research from the University of Sao Paulo, "However, the effect of these drugs on skeletal myopathy needs to be clarified, since exercise intolerance remains in HF patients optimized with b-blockers and inhibitors of RAS. Aerobic exercise training (AET) is efficient in counteracting skeletal myopathy and in improving functional capacity and quality of life. Indeed, AET has beneficial effects on failing heart itself despite being of less magnitude compared with neurohumoral blockade. In this way, AET should be implemented in the care standards, together with pharmacological therapies. Since both neurohumoral inhibition and AET have a direct and/or indirect impact on skeletal muscle, this review aims to provide an overview of the isolated effects of these therapeutic approaches in counteracting skeletal myopathy in HF."

According to the news editors, the research concluded: "The similarities and dissimilarities of neurohumoral inhibition and AET therapies are also discussed to identify potential advantageous effects of these combined therapies for treating HF."

The news editors report that additional information may be obtained by contacting A.V. Bacurau, School of Physical Education and Sport, University of Sao Paulo, 05508-030 Sao Paulo, SP, Brazil. Additional authors for this research include T.F. Cunha, R.W. Souza, V.A. Voltarelli, D. Gabriel-Costa and P.C Brum.

Researchers at University of Sao Paulo Report Findings in Hematopoietic Stem Cells (Does ex vivo CD34+ positive selection influence outcome after autologous hematopoietic stem cell transplantation in systemic sclerosis patients?)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Stem Cell Research - Hematopoietic Stem Cells are discussed in a new report. According to news originating from Ribeirao Preto, Brazil, by NewsRx correspondents, research stated, "This EBMT Autoimmune Disease Working Party study aimed to evaluate the influence of CD34+ positive graft selection (CD34+) on the outcome of systemic sclerosis (SSc) patients after autologous hematopoietic stem cell transplantation (AHSCT). Clinical and laboratory data from 138 SSc patients at diagnosis, before and after AHSCT were retrospectively analyzed."

Our news journalists obtained a quote from the research from the University of Sao Paulo, "CD34+ selection was performed in 47.1% (n=65) patients. By multivariate analysis adjusting for all factors differing between the two groups (without or with CD34+), there was no statistically significant difference in terms of overall survival (hazard ratio (HR): 0.98, 95% confidence interval (CI) 0.40-2.39, p=0.96), PFS (HR: 1.55, 95% CI 0.83-2.88, p=0.17) and incidence of relapse or progression (HR: 1.70, 95% CI 0.85-3.38, p=0.13). We demonstrate that CD34+ does not add benefit to the outcome of SSc patient treated with AHSCT."

According to the news editors, the research concluded: "These findings should be further confirmed by prospective randomized trials."

For more information on this research see: Does ex vivo CD34+ positive selection influence outcome after autologous hematopoietic stem cell transplantation in systemic sclerosis patients? Researchers at University of Sao Paulo Report New Data on Human Herpesvirus 8 (Genotypic distribution of HHV-8 in AIDS individuals without and with Kaposi sarcoma Is genotype B associated with better prognosis of AIDS-KS?)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Human Herpesvirus Diseases and Conditions - Human Herpesvirus 8 is the subject of a report. According to news reporting out of Sao Paulo, Brazil, by NewsRx editors, research stated, "AIDS-associated Kaposi's sarcoma (AIDS-KS) caused by human herpes virus 8 (HHV-8) is the most severe and resistant form of KS tumor. Our aim was to verify whether there is an association between HHV-8 variability and development of AIDS-KS in Brazil by comparing the HHV-8 variability between individuals without and with KS."

Our news journalists obtained a quote from the research from the University of Sao Paulo, "Saliva samples and blood, when available, were analyzed by PCR techniques for detection of the fragments of ORF K1 of HHV-8, which were then genotyped and analyzed regarding the genetic variability. Our study described 106 positive cases for HHV-8 in the saliva from 751 AIDS patients without previous KS. In addition, we performed a phylogenetic analysis of HHV-8 in 34 of the 106 AIDS patients without KS and in 33 of the 37 patients with active KS. The distribution of HHV-8 genotypes A, B, C, and F in AIDS individuals was indistinguishable by comparing non-KS and KS groups, as well as regarding ethnicity. Considering the KS group, genotype B was associated with better prognosis of KS tumor. Interestingly, we found a particular profile of diversity within Glade C and 2 recombinant patterns of HHV-8 in the saliva of AIDS individuals without KS. We emphasize the need to achieve standard genotyping protocol for ORF K1 amplification, thus allowing for substantial detection of HHV-8 variants."

According to the news editors, the research concluded: "Our findings can shed light on the role of HHV-8 variability in the pathogenesis of AIDS-KS."

For more information on this research see: Genotypic distribution of HHV-8 in AIDS individuals without and with Kaposi sarcoma Is genotype B associated with better prognosis of AIDS-KS? *Medicine*, 2016;95(48):60-67. *Medicine* can be contacted at: Lippincott Williams & Wilkins, Two Commerce Sq, 2001 Market St, Philadelphia, PA 19103, USA. Researchers at University of Sao Paulo Target Ovarian Cancer
(Germline mutations in BRCA1 and BRCA2 in epithelial ovarian cancer patients in Brazil)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Oncology - Ovarian Cancer. According to news reporting from Sao Paulo, Brazil, by NewsRx journalists, research stated, "Approximately 8-15% epithelial ovarian cancer patients are BRCA1 or BRCA2 germline mutation carriers. Brazilian inhabitants may have peculiar genetic characteristics associated with ethnic diversity, and studies focusing on the entire BRCA1/BRCA2 gene sequencing in Brazilian ovarian cancer patients are still lacking."

The news correspondents obtained a quote from the research from the University of Sao Paulo, "The aim of this study was to evaluate BRCA1/2 mutations, through entire gene sequencing, in a Brazilian population of women with epithelial ovarian cancer. In a cross sectional study performed in one reference centre for cancer treatment in Sao Paulo, Brazil, 100 patients diagnosed with epithelial ovarian cancer unselected for family history of breast and/or ovarian cancer were included. The complete coding sequence of BRCA1/2 genes was evaluated through Next-Generation or capillary sequencing. Large deletions were investigated through Multiplex Ligation-dependent Probe Amplification (MLPA). Nineteen pathogenic mutations (BRCA1: n = 17 and BRCA2: n = 2) featuring 14 different mutations, including two large deletions in BRCA1 (exon 1-2 deleted and exon 5-7 deleted) were identified. Three mutations were detected more than once (c.3331_3334delCAAG, c.5266dupC and c.4484G>T). Two novel frameshift mutations were identified, one in BRCA1 (c.961_962delTG) and one in BRCA2 (c.1963_1963delC). BRCA1/2 mutations were seen in 35.5% of the patients with first and/or second-degree relatives with breast and/or ovarian cancer. Nineteen variants of uncertain significance (VUS) were detected (BRCA1: n = 2 and BRCA2: n = 17), including five distinct missense variants (BRCA1: c.5348 T>C; BRCA2: c.2350A>G, c.3515C>T, c.7534C>T, and c.8351G>A). Among epithelial ovarian cancer patients unselected for family history of cancer, 19% were BRCA1/2 germline mutation carriers. Almost 3/4 of the BRCA mutations, including two large deletions, were detected only once."

According to the news reporters, the research concluded: "Our work emphasizes the need of entire gene sequencing and MLPA screening in Brazil."

For more information on this research see: Germline mutations in BRCA1 and BRCA2 in epithelial ovarian cancer patients in Brazil. *BMC Cancer*, 2016;16():9-16. *BMC Cancer* can be contacted at: Biomed Central Ltd, 236 Grays Inn Rd, Floor 6, London WC1X 8HL, England. Researchers at University of Seville Report New Data on Squamous Cell Carcinoma (Is there an association between dental implants and squamous cell carcinoma?)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Oncology - Squamous Cell Carcinoma are discussed in a new report. According to news reporting out of Seville, Spain, by NewsRx editors, research stated, "The complications associated with dental implants are numerous, most of them of an inflammatory nature; nevertheless, some isolated cases of oral squamous cell carcinoma (OSCC) have been found in the vicinity of the implants. The objective of the present article is to know whether there is an association between dental implants and the development of OSCC."

Our news journalists obtained a quote from the research from the University of Seville, "A search was carried out in Medline, Tripdatabase and Cochrane with the keywords 'dental implants' AND `squamous cell carcinoma', and 'dental implant complications' AND `squamous cell carcinoma.' The criteria for inclusion were articles published in English that dealt with the possible carcinogenic effects of implants and the possible malign transformation of oral lesions after the insertion of the implants. For the analysis, cases were used in which an OSCC had appeared in the periimplantary mucosa. After an initial search, 269 articles were selected, of which 197 were excluded as not being directly related to the subject. Finally, 45 articles were selected, with 23 of them being used in the analysis. In these, 46 cases of OSCC in the vicinity of implants were discussed. Chronic inflammation in itself can lead to a malign transformation of the oral tissue, while in other cases it is caused and modulated by carcinogens, genetic factors or inherent factors in the patient, or by the dental implants. It is not possible to establish a cause-effect relation between the implants and the development of OSCC. Its presence can be confused with peri-implantitis, so that in the cases where it appears suddenly, does not respond to conventional treatment and/or there is anaesthesia or paresthesia, it is advisable to do a biopsy. It is important to make an adequate selection of the patient and reduce or eliminate the risk factors."

According to the news editors, the research concluded: "The findings of the present review are based on case study level of evidence, so meta-analysis is needed to further draw from these results."

For more information on this research see: Is there an association between dental implants and squamous cell carcinoma? *British Dental Journal*, 2016;221(10):645-649.

*British Dental Journal* can be contacted at: Nature Publishing Group, Macmillan Building, 4 Crinan St, London N1 9XW, England. (Nature Publishing Group - www.nature.com/; British Dental Journal - www.nature.com/bdj/)

Our news journalists report that additional information may be obtained by contacting A.O. Salgado-Peralvo, Univ Seville, Family & Community Dental, Seville, Spain. Additional authors for this research include L. Arriba-Fuente, M.V. Mateos-Moreno and A. Salgado-Garcia.

Researchers at University of Sfax Target Vibrionaceae (Molecular Detection of the Three Major Pathogenic Vibrio Species from Seafood Products and Sediments in Tunisia Using Real-Time PCR)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Gram-Negative Bacteria - Vibrionaceae have been presented. According to news reporting out of Sfax, Tunisia, by NewsRx editors, research stated, "Vibrio spp. have emerged as a serious threat to human health worldwide. V. parahaemolyticus, V. cholerae, and V. vulnificus pose a considerable public health risk in Tunisia because they cause sporadic and epidemic foodborne infections associated with the consumption of raw or undercooked contaminated seafood. More recently, toxR-positive V. alginolyticus was also reported to be a potential source of contaminated seafood."

Our news journalists obtained a quote from the research from the University of Sfax, "A total of 247 samples, including 113 fishes (Labrus viridis, Penaeus kerathurus, Diplodus annularis, Diplodus sparaillon, Scorparna porcus, Sarpa salpa, Dentex dentex, Scorparna scrofa, Sardinella aurita, Trachurus trachurus, Synodus saurus, Pagellus euthrinus, and Metapenaeus monoceros), 83 clams (Ruditapes decussatus species), 30 seawater samples, and 21 sediment samples were analyzed using traditional culture methods (ISO/TS 21872-1; International Organization for Standardization 2007) and a conventional PCR method for Vibrio spp. identification. A rapid, sensitive, and highly reproducible real-time PCR assay was developed to detect the three major Vibrio spp. pathogenic for humans in Tunisian seafood products and sediments. A conventional culture method found 102 (41.3%) of 247 analyzed samples positive for Vibrio spp.; a conventional PCR method found 126 (51%) of the 247 samples positive. Real-time PCR assay found 126 (51.1%) samples positive; V. alginolyticus toxR was the most common, found in 99 (78.57%) of samples, followed by V. parahaemolyticus in 26 (20.63%) and V. cholerae in 1 (0.7%). All culture-positive samples were PCR positive. However, 24 samples that were positive by conventional PCR and real-time PCR were culture negative. Our findings indicate that retail seafood is commonly contaminated with Vibrio spp. and presents a potential risk to human health in Tunisia."

According to the news editors, the research concluded: "These data also indicate that real-time PCR can provide sensitive species-specific detection of Vibrio spp. in seafood without prior isolation and characterization of the bacteria by traditional microbiological methods."

For more information on this research see: Molecular Detection of the Three Major Pathogenic Vibrio Species from Seafood Products and Sediments in Tunisia Using Real-Time PCR. *Journal of Food Protection*, 2016;79(12):2086-2094. *Journal of Food Protection* can be contacted at: Int Assoc Food Protection, 6200 Aurora Ave Suite 200W, Des Moines, IA 50322-2863, USA.

Researchers at University of South Australia Describe Findings in Drug Delivery Systems ("Thunderstruck" Plasma-Polymer-Coated Porous Silicon Microparticles As a Controlled Drug Delivery System)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Drugs and Therapies - Drug Delivery Systems. According to news reporting from Adelaide, Australia, by NewsRx journalists, research stated, "Controlling the release kinetics from a drug carrier is crucial to maintain a drug's therapeutic window. We report the use of biodegradable porous silicon microparticles (pSi MPs) loaded with the anticancer drug camphothecin, followed by a plasma polymer overcoating using a loudspeaker plasma reactor."

The news correspondents obtained a quote from the research from the University of South Australia, "Homogenous 'Teflon-like' coatings were achieved by tumbling the particles by playing AC/DC's song 'Thunderstruck'. The overcoating resulted in a markedly slower release of the cytotoxic drug, and this effect correlated positively with the plasma polymer coating times, ranging from 2-fold up to more than 100-fold."

According to the news reporters, the research concluded: "Ultimately, upon characterizing and verifying pSi MP production, loading, and coating with analytical methods such as time-of-flight secondary ion mass spectrometry, scanning electron microscopy, thermal gravimetry, water contact angle measurements, and fluorescence microscopy, human neuroblastoma cells were challenged with pSi MPs in an in vitro assay, revealing a significant time delay in cell death onset."

For more information on this research see: "Thunderstruck" Plasma-Polymer-Coated Porous Silicon Microparticles As a Controlled Drug Delivery System. Acs Applied Materials & Interfaces, 2016;8(7):4467-76. (American Chemical Society - www.acs.org; Acs Applied Materials & Interfaces - www.pubs.acs.org/journal/aamick)

Researchers at University of South Florida Target Proteomics (g-AApeptides: Design, Structure, and Applications)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Proteomics. According to news reporting from Tampa, Florida, by NewsRx journalists, research stated, "The development of sequence-specific peptidomimetics has led to a variety of fascinating discoveries in chemical biology. Many peptidomimetics can mimic primary, secondary, and even tertiary structure of peptides and proteins, and because of their unnatural backbones, they also possess significantly enhanced resistance to enzymatic hydrolysis, improved bioavailability, and chemodiversity."

Financial supporters for this research include Division of Chemistry, National Institute of General Medical Sciences.

The news correspondents obtained a quote from the research from the University of South Florida, "It is known that peptide nucleic acids (PNAs) are peptidic sequences developed for the mimicry of nucleic acids; however, their unique backbone as the molecular scaffold of peptidomimetics to mimic structure and function of bioactive peptides has not been investigated systematically. As such, we recently developed a new class of peptidomimetics, 'g-AApeptides', based on the chiral g-PNA backbone. They are termed g-AApeptides because they are the oligomers of g-substituted-N-acylated-N-aminoethyl amino acids. Similar to other classes of peptidomimetics, g-AApeptides are also resistant to proteolytic degradation and possess the potential to enhance chemodiversity. Moreover, in our scientific journey on the exploration of this class of peptidomimetics, we have discovered some intriguing structures and functions of g-AApeptides. In this Account, we summarize the current development and application of g-AApeptides with biological potential. Briefly, both linear and cyclic (either through head-to-tail or head-to-side-chain cyclization) g-AApeptides with diverse functional groups can be synthesized easily on the solid phase using the synthetic protocol we developed. g-AApeptides could mimic the primary structure of peptides, as they project the same number of side chains as peptides of the same lengths. For instance, they could mimic the Tat peptide to permeate cell membranes and bind to HIV RNA with high specificity and affinity. Certain g-AApeptides show similar activity to the RGD peptide and target integrin specifically on the cell surface. g-AApeptides with function akin to fMLF peptides are also identified. More importantly, we found that g-AApeptides can fold into discrete secondary structures, such as helical and b-turn-like structures. Therefore, they could be rationally designed for a range of biological applications. For instance, g-AApeptides can mimic host-defense peptides and display potent and broad-spectrum activity toward a panel of drug-resistant bacterial pathogens. Meanwhile, because of their stability against proteolysis and their chemodiversity, g-AApeptides are also amenable for combinatorial screening. We demonstrate that, through combinatorial selection, certain g-AApeptides are identified to inhibit Ab40 peptide aggregation, suggesting their
potential use as a molecular probe to intervene in Alzheimer's disease. In addition, a few g-AAPeptides identified from the g-AApeptide library have been shown to bind to the DNA-binding domain of STAT3 and antagonize STAT3/DNA interactions.

According to the news reporters, the research concluded: "Our studies suggest that, with further studies and exploration on both structures and functions, g-AApeptides may emerge to be a new class of peptidomimetics that play an important role in chemical biology and biomedical sciences."

Our news journalists report that additional information may be obtained by contacting Y. Shi, Dept. of Chemistry, University of South Florida , 4202 East Fowler Ave, Tampa, Florida 33620, United States. Additional authors for this research include P. Teng, P. Sang, F. She, L. Wei and J. Cai.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1021/acs.accounts.5b00492. This DOI is a link to an online electronic document that is either free or for purchase.

Nutritional and Metabolic Diseases and Conditions -...

Researchers at University of Sydney Report Findings in Type 2 Diabetes
[Low alanine aminotransferase levels and higher number of cardiovascular events in people with Type 2 diabetes: analysis of the Fenofibrate Intervention and Event Lowering in ...]

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Nutritional and Metabolic Diseases and Conditions - Type 2 Diabetes are discussed in a new report. According to news originating from Sydney, Australia, by NewsRx correspondents, research stated, "To determine whether alanine aminotransferase or gamma-glutamyltransferase levels, as markers of liver health and non-alcoholic fatty liver disease, might predict cardiovascular events in people with Type 2 diabetes. Data from the Fenofibrate Intervention and Event Lowering in Diabetes study were analysed to examine the relationship between liver enzymes and incident cardiovascular events (non-fatal myocardial infarction, stroke, coronary and other cardiovascular death, coronary or carotid revascularization) over 5 years."

Funders for this research include Australian branch of the Thessalian Society, Diabetes Research Foundation, University of Sydney, National Health and Medical Research Council, Fournier Laboratories.

Our news journalists obtained a quote from the research from the University of Sydney, "Alanine aminotransferase measure had a linear inverse relationship with the first cardiovascular event occurring in participants during the study period. After adjustment, for every 1 sd higher baseline alanine aminotransferase measure (13.2 U/l), the risk of a cardiovascular event was 7% lower (95% CI 4-13; p=0.02). Participants with alanine
aminotransferase levels below and above the reference range 8-41 U/l for women and 9-59 U/l for men, had hazard ratios for a cardiovascular event of 1.86 (95% CI 1.12-3.09) and 0.65 (95% CI 0.49-0.87), respectively (p=0.001). No relationship was found for gamma-glutamyltransferase.

According to the news editors, the research concluded: "The data may indicate that in people with Type 2 diabetes, which is associated with higher alanine aminotransferase levels because of prevalent non-alcoholic fatty liver disease, a low alanine aminotransferase level is a marker of hepatic or systemic frailty rather than health."

For more information on this research see: Low alanine aminotransferase levels and higher number of cardiovascular events in people with Type 2 diabetes: analysis of the Fenofibrate Intervention and Event Lowering in Diabetes (FIELD) study. Diabetic Medicine, 2015;33(3):356-64. (Wiley-Blackwell - www.wiley.com; Diabetic Medicine - onlinelibrary.wiley.com/journal/10.1111/(ISSN)1464-5491)

The news correspondents report that additional information may be obtained from K.H. Williams, Sydney Medical School, University of Sydney, Sydney, NSW, Australia. Additional authors for this research include D.R. Sullivan, A.S. Veillard, R. O'Brien, J. George, A.J. Jenkins, S. Young, C. Ehnholm, A. Duffield, S.M. Twigg and A.C Keech.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1111/dme.12972. This DOI is a link to an online electronic document that is either free or for purchase.

Physiology, Nutrition and Metabolism

Researchers at University of Sydney Target Physiology, Nutrition and Metabolism (Associations between CD36 gene polymorphisms and metabolic response to a short-term endurance-training program in a young-adult population)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Physiology, Nutrition and Metabolism are presented in a new report. According to news reporting originating in Lidcombe, Australia, by NewsRx journalists, research stated, "Recent studies have shown that CD36 gene variants are associated with an increased prevalence of chronic disease. Although a genetic component to trainability has been proven, no data are available specifically on the influence of CD36 on training response."

The news reporters obtained a quote from the research from the University of Sydney, "Two single nucleotide polymorphisms (SNPs) (rs1527479 and rs1984112) were assessed for associations with whole-body substrate oxidation, response to a 75-g dextrose oral glucose tolerance test, fasting plasma lipids, and cardiovascular disease risk factors in a young healthy cohort, both using cross-sectional analysis and following a 4-week endurance-exercise training program. Genotyping was performed using real-time polymerase chain reaction. Cross-
sectional data were collected in 34 individuals (age, 22.7 ± 3.5 years), with 17 completing the training program. At baseline, TT SNP carriers at rs1527479 and wild-type GG carriers at rs1984112 were associated with significantly greater whole-body rate of fat oxidation (Fatox) during submaximal exercise (p <0.05), whilst AA carriers at the same position were associated with elevated triglyceride (TG) levels. A significant genotype × time interaction in Fatox at SNP rs1984112 was identified at rest. Significant genotype × time interactions were present at rs1527479, with TT carriers exhibiting a favourable response to training when compared with C-allele carriers for fasting TG, diastolic blood pressure (DBP), and mean arterial pressure (MAP)."

According to the news reporters, the research concluded: "Cross-sectional assessment identified associations with Fatox and TG. Training response at both SNPs identified 'at-risk' genotypes responding favourably to the training stimulus in Fatox, TG, DBP, and MAP. Although these data show potential pleiotropic influence of CD36 SNPs, assessment in a larger cohort is warranted."

Our news correspondents report that additional information may be obtained by contacting A.F. Jayewardene, a Exercise Health and Performance Faculty Research Group, Faculty of Health Sciences, University of Sydney, Lidcombe, NSW, Australia. Additional authors for this research include Y. Mavros, T. Gwinn, D.P. Hancock and K.B Rooney.

Hematology - Blood Coagulation Factors

Researchers at University of Tasmania Target Blood Coagulation Factors [Platelet-activating factor receptor (PAFr) is upregulated in small airways and alveoli of smokers and COPD patients]

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Hematology - Blood Coagulation Factors. According to news reporting originating in Hobart, Australia, by NewsRx journalists, research stated, "PAFr is a cell adhesion site for specific bacteria, notably non-typeable Haemophilus influenzae (NTHi) and Streptococcus pneumoniae. We previously published that..."
PAFr expression is significantly upregulated in the large airways of smokers, especially in COPD."

Financial support for this research came from National Health and Medical Research Council.

The news reporters obtained a quote from the research from the University of Tasmania, "We have now investigated PAFr expression in the epithelium and Rbm of small airways and in the alveolar compartment in smokers and patients with both COPD and small airway disease. We evaluated PAFr expression cross-sectionally in resected lung tissue from: eight smokers with normal lung function (NLFS); 10 with smoking-related small airway narrowing only; eight COPD smokers; 10 COPD ex-smokers, and compared these with nine control tissues. Anti-PAFr immunostaining was quantified using computer-aided image analysis. Significantly increased PAFr expression in small airway epithelium of all clinical groups was found compared with controls (p <0.01). Moreover, epithelial PAFr expression was upregulated in COPD smokers compared with NLFS (p <0.05), but not when compared with COPD ex-smokers or patients with only small airways disease. Smoking history (pack-year) correlated significantly with PAFr expression in the currently smoking individuals, especially in NLFS (r=0.9; p<0.002). An increase above normal in PAFr-expressing cells in the airway epithelial Rbm was only significant in COPD smokers (p <0.007). An upregulation of PAFr-expressing cell in alveolar epithelium was uniformly found in all clinical groups compared with normal control (p <0.01). Epithelial PAFr expression is upregulated in small airways and alveoli in smokers and COPD."

According to the news reporters, the research concluded: "Increased expression of PAFr could be crucial in facilitating acute and chronic respiratory infection with specific respiratory pathogens."

Our news correspondents report that additional information may be obtained by contacting S.D. Shukla, NHMRC Centre of Research Excellence for Chronic Respiratory Disease, School of Medicine, University of Tasmania, Hobart, Tasmania, Australia. Additional authors for this research include H.K. Muller, R. Latham, S.S. Sohal and E.H Walters.

**Oncology - Acute Myeloid Leukemia**

**Researchers at University of Texas Release New Data on Acute Myeloid Leukemia (Double minute chromosomes in acute myeloid leukemia, myelodysplastic syndromes, and chronic myelomonocytic leukemia are associated with micronuclei, MYC or MLL ...)**
2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Oncology - Acute Myeloid Leukemia is now available. According to news reporting originating from Houston, Texas, by NewsRx correspondents, research stated, "Double minute chromosomes (dmin) are small, paired chromatin bodies that lack a centromere and represent a form of extrachromosomal gene amplification. Dmin are rare in myeloid neoplasms and are generally associated with a poor prognosis."

Our news editors obtained a quote from the research from the University of Texas, "Most studies of dmin in myeloid neoplasms are case reports or small series. In the current study, we present the clinicopathologic and cytogenetic features of 22 patients with myeloid neoplasms harboring dmin. These neoplasms included acute myeloid leukemia (AML) (n = 18), myelodysplastic syndrome (MDS) (n = 3), and chronic myelomonocytic leukemia (CMML) (n = 1). The AML cases consisted of AML with myelodysplasia-related changes (n = 13) and therapy-related AML (n = 5). Dmin were detected in initial pre-therapy samples in 14 patients with AML or CMML; they were acquired during the disease course in 8 patients who had AML or MDS. The presence of dmin was associated with micronuclei (18/18; 100%), complex karyotype (17/22; 77.3%), and amplification of MYC (12/16; 75%) or MLL (4/16; 25%). Immunohistochemical staining for MYC performed on bone marrow core biopsy or clot sections revealed increased MYC protein in all 19 cases tested. Except for one patient, most patients failed to respond to risk-adapted chemotherapies. At last follow up, all patients had died of disease after a median of 5 months following dmin detection."

According to the news editors, the research concluded: "Dmin in myeloid neoplasms commonly harbor MYC or MLL gene amplification and manifest as micronuclei within leukemic blasts. Dmin are often associated, with myelodysplasia or therapy related disease, and complex karyotypes."

For more information on this research see: Double minute chromosomes in acute myeloid leukemia, myelodysplastic syndromes, and chronic myelomonocytic leukemia are associated with micronuclei, MYC or MLL amplification, and complex karyotype. Cancer Genetics, 2016;209(7-8):313-320. Cancer Genetics can be contacted at: Elsevier Science Inc, 360 Park Ave South, New York, NY 10010-1710, USA. Researchers at University of Texas Southwestern Have Reported New Data on Melanoma (Immune-mediated Disease in Ipilimumab Immunotherapy of Melanoma with FDG PET-CT)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Oncology-Melanoma have been published. According to news reporting originating in Dallas, Texas, by NewsRx journalists, research stated, "The purposes of this study were to provide a case-based overview of various immune-mediated side effects detected by 18F-Fluorodeoxyglucose (F-18 FDG) positron emission tomography-computed tomography (PET-CT) in the patients receiving ipilimumab immunotherapy for treatment of malignant melanoma, and discuss the importance of recognizing immune mediated side effects in the use of F-18 FDG PET-CT for monitoring therapeutic effects of ipilimumab on metastatic melanoma. This is a retrospective case series study of the patients diagnosed with melanoma who were subjected to immunomodulating therapy with ipilimumab."

Financial support for this research came from University of Texas Southwestern Medical Center.

The news reporters obtained a quote from the research from the University of Texas Southwestern, "F-18 FDG PET-CT findings were reviewed, and the patients with immune-mediated side effects were selected for further analysis, in conjunction with review of clinical progress notes, the results of laboratory tests, and findings of other imaging tests. Four patients with immune-mediated side effects were identified among the patients being treated with ipilimumab and subjected to F-18 FDG PET-CT for monitoring therapeutic effects. These immune mediated side effects include new findings of abnormal increased FDG uptake associated with immune-mediated pancreatitis and hypophysitis, as well as immune-mediated thyroiditis and colitis reported previously. Various immune-mediated side effects were detected by F-18 FDG PET-CT in the patients subjected to immunomodulating therapy with ipilimumab."

According to the news reporters, the research concluded: "It is essential for the interpreting provider to recognize and differentiate abnormal FDG uptake associated with immune-mediated side effects from hypermetabolic malignant lesions when using F-18 FDG PET-CT for monitoring therapeutic effects of ipilimumab on melanoma lesions."

Our news correspondents report that additional information may be obtained by contacting J.W. Wachsmann, Univ Texas Southwestern Med Center Dallas, Dept. of Radiol, Dallas, TX 75390, United States. Additional authors for this research include R. Ganti and F.Y. Peng.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1016/j.acra.2016.08.005. This DOI is a link to an online electronic document that is either free or for purchase.

K-Nearest Neighbor

Researchers at University of Toronto Detail Findings in K-Nearest Neighbor (Sample size requirements for knowledge-based treatment planning)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on K-Nearest Neighbor. According to news reporting out of Toronto, Canada, by NewsRx editors, research stated, "To determine how training set size affects the accuracy of knowledge-based treatment planning (KBP) models. The authors selected four models from three classes of KBP approaches, corresponding to three distinct quantities that KBP models may predict: dose-volume histogram (DVH) points, DVH curves, and objective function weights."

Financial support for this research came from Natural Sciences and Engineering Research Council of Canada (NSERC).

Our news journalists obtained a quote from the research from the University of Toronto, "DVH point prediction is done using the best plan from a database of similar clinical plans; DVH curve prediction employs principal component analysis and multiple linear regression; and objective function weights uses either logistic regression or K-nearest neighbors. The authors trained each KBP model using training sets of sizes n=10, 20, 30, 50, 75, 100, 150, and 200. The authors set aside 100 randomly selected patients from their cohort of 315 prostate cancer patients from Princess Margaret Cancer Center to serve as a validation set for all experiments. For each value of n, the authors randomly selected 100 different training sets with replacement from the remaining 215 patients. Each of the 100 training sets was used to train a model for each value of n and for each KBT approach. To evaluate the models, the authors predicted the KBP endpoints for each of the 100 patients in the validation set. To estimate the minimum required sample size, the authors used statistical testing to determine if the median error for each sample size from 10 to 150 is equal to the median error for the maximum sample size of 200. The minimum required sample size was different for each model. The DVH point prediction method predicts two dose metrics for the bladder and two for the rectum. The authors found that more than 200 samples were required to achieve consistent model predictions for all four metrics. For DVH curve prediction, the authors found that at least 75 samples were needed to accurately predict the bladder DVH, while only 20 samples were needed to predict the rectum DVH. Finally, for objective function weight prediction, at least 10 samples were needed to train the logistic regression model, while at least 150 samples were required to train the K-nearest neighbor methodology. In conclusion, the minimum required sample size needed to accurately train KBP models for prostate cancer depends on the specific model and endpoint to be predicted."

According to the news editors, the research concluded: "The authors' results may provide a lower bound for more complicated tumor sites."

For more information on this research see: Sample size requirements for knowledge-based treatment planning. *Medical Physics*, 2016;43(3):1212-21. *Medical Physics* can be
Researchers at University of Tours Target Breast Cancer (Intrinsic and extrinsic flaws of the nomogram predicting bone-only metastasis in women with early breast cancer: An external validation study)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Oncology - Breast Cancer. According to news originating from Tours, France, by NewsRx correspondents, research stated, "The recently developed MDACC nomogram purports to predict the risk of bone-only metastasis in women with early breast carcinoma based on five clinical and pathological characteristics. We set out to externally validate and assess its robustness using a tertiary breast cancer centre database."

Our news journalists obtained a quote from the research from the University of Tours, "All consecutive women treated for early breast cancer in our centre between January 1989 and December 2013 and who had all the nomogram variables documented were eligible for analysis. We identified 1255 eligible women for external validation analysis. The median follow-up was 54 months (range: 1-312) and time to initial metastasis 20 months (range: 1-80). The correspondence between the actual bone-only metastasis and the nomogram predictions implied poor calibration of the nomogram in the validation cohort, be it in the whole cohort or when stratified by breast cancer subtype."

According to the news editors, the research concluded: "This external validation study of the MDACC nomogram showed limitations in its generalizability to a new and independent European patient population."

Researchers at University of Utah Have Reported New Data on Mantle Cell Lymphoma (Ibrutinib in mantle cell lymphoma patients: glass half full? Evidence and opinion)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Oncology - Mantle Cell Lymphoma. According to news reporting originating from Salt Lake City, Utah, by NewsRx correspondents, research stated, "Mantle cell lymphoma (MCL) is a rare subtype of non-Hodgkin's lymphoma typically marked by an aggressive clinical course and a predilection for relapse. The B-cell receptor (BCR) signaling survival pathway is chronically activated in MCL, contributing to its pathogenesis."

Our news editors obtained a quote from the research from the University of Utah, "Ibrutinib is an inhibitor of Bruton's tyrosine kinase, a vital component of this pathway. This article details the current clinical experience with ibrutinib in the treatment of patients with MCL, including completed and published clinical trials and reviews potential adverse events (AEs) and pitfalls associated with ibrutinib therapy. Although most AEs experienced by patients treated with ibrutinib are mild, some can be severe and treatment limiting and may be attributed to off-target effects. Ibrutinib is a very promising agent for patients with MCL with notable response rates. However, when used as a single agent, around one third of patients relapse in the first 2 years of treatment. Recently reported combination therapies have shown significant activity. Emerging data evaluating potential mechanisms of drug resistance and the poor clinical outcomes after treatment failure are also discussed. Further understanding of resistance and its implications not only in relapsed disease but in the frontline setting are needed. Investigation of strategies to overcome resistance remains an area of high unmet clinical need."

According to the news editors, the research concluded: "Evaluation of the impact of shorter treatment duration, effects on minimal residual disease, and incorporation of novel combinations are also warranted."

For more information on this research see: Ibrutinib in mantle cell lymphoma patients: glass half full? Evidence and opinion. Therapeutic Advances In Hematology, 2015;6 (5):242-52. (Sage Publications - www.sagepub.com/; Therapeutic Advances In Hematology - tah.sagepub.com)

Researchers at University of Utah Release New Data on Blood Coagulation Disorders (Factor V Leiden, prothrombin G20210A, and methylene tetrahydrofolate reductase mutations and stillbirth: the Stillbirth Collaborative Research Network)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Hematologic Diseases and Conditions - Blood Coagulation Disorders. According to news reporting originating from Salt Lake City, Utah, by NewsRx correspondents, research stated, "An evaluation for heritable thrombophilias is recommended in the evaluation of stillbirth. However, the association between thrombophilias and stillbirth remains uncertain."

Our news editors obtained a quote from the research from the University of Utah, "We sought to assess the association between maternal and fetal/placental heritable thrombophilias and stillbirth in a population-based, case-control study in a geographically, racially, and ethnically diverse population. We conducted secondary analysis of data from the Stillbirth Collaborative Research Network, a population-based case-control study of stillbirth. Testing for factor V Leiden, prothrombin G20210A, methylene tetrahydrofolate reductase C677T and A1298C, and plasminogen activating inhibitor (PAI)-1 4G/5G mutations was done on maternal and fetal (or placental) DNA from singleton pregnancies. Data analyses were weighted for oversampling and other aspects of the design. Odds ratios (OR) were generated from univariate models regressing stillbirth/live birth status on each thrombophilia marker. Results were available for >= 1 marker in 488 stillbirths and 1342 live birth mothers and 405 stillbirths and 990 live birth fetuses. There was an increased odds of stillbirth for maternal homozygous factor V Leiden mutation (2/488; 0.4% vs 1/1380; 0.0046%; OR, 87.44; 95% confidence interval, 7.88-970.92). However, there were no significant differences in the odds of stillbirth for any other maternal thrombophilia, even after stratified analyses. Fetal 4G/4G PAI-1 (OR, 0.63; 95% confidence interval, 0.43-0.91) was associated with decreased odds of stillbirth. Other fetal thrombophilias were similar among groups. Most maternal and fetal thrombophilias were not associated with stillbirth. Maternal factor V Leiden was weakly associated with stillbirth, and the fetal PAI-1 4G/4G polymorphism was associated with live birth."

According to the news editors, the research concluded: "Our data do not support routine testing for heritable thrombophilias as part of an evaluation for possible causes of stillbirth."
Researchers at University of Valencia Target Angina Pectoris
(Cardiovascular and Renal Outcomes of Renin-Angiotensin System Blockade in Adult Patients with Diabetes Mellitus: A Systematic Review with Network Meta-Analyses)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Heart Disorders and Diseases - Angina Pectoris. According to news reporting originating from Valencia, Spain, by NewsRx correspondents, research stated, "Medications aimed at inhibiting the renin-angiotensin system (RAS) have been used extensively for preventing cardiovascular and renal complications in patients with diabetes, but data that compare their clinical effectiveness are limited. We aimed to compare the effects of classes of RAS blockers on cardiovascular and renal outcomes in adults with diabetes."

Our news editors obtained a quote from the research from the University of Valencia, "Eligible trials were identified by electronic searches in PubMed/MEDLINE and the Cochrane Database of Systematic Reviews (1 January 2004 to 17 July 2014). Interventions of interest were angiotensin-converting enzyme (ACE) inhibitors, angiotensin receptor blockers (ARBs), and direct renin (DR) inhibitors. The primary endpoints were cardiovascular mortality, myocardial infarction, and stroke-singly and as a composite endpoint, major cardiovascular outcome-and end-stage renal disease [ESRD], doubling of serum creatinine, and all-cause mortality-singly and as a composite endpoint, progression of renal disease. Secondary endpoints were angina pectoris and hospitalization for heart failure. In all, 71 trials (103,120 participants), with a total of 14 different regimens, were pooled using network meta-analyses. When compared with ACE inhibitor, no other RAS blocker used in monotherapy and/or combination was associated with a significant reduction in major cardiovascular outcomes: ARB (odds ratio
[OR] 1.02; 95% credible interval [CrI] 0.90-1.18), ACE inhibitor plus ARB (0.97; 95% CrI 0.79-1.19), DR inhibitor plus ACE inhibitor (1.32; 95% CrI 0.96-1.81), and DR inhibitor plus ARB (1.00; 95% CrI 0.73-1.38). For the risk of progression of renal disease, no significant differences were detected between ACE inhibitor and each of the remaining therapies: ARB (OR 1.10; 95% CrI 0.90-1.40), ACE inhibitor plus ARB (0.97; 95% CrI 0.72-1.29), DR inhibitor plus ACE inhibitor (0.99; 95% CrI 0.65-1.57), and DR inhibitor plus ARB (1.18; 95% CrI 0.78-1.84). No significant differences were showed between ACE inhibitors and ARBs with respect to all-cause mortality, cardiovascular mortality, myocardial infarction, stroke, angina pectoris, hospitalization for heart failure, ESRD, or doubling serum creatinine. Findings were limited by the clinical and methodological heterogeneity of the included studies. Potential inconsistency was identified in network meta-analyses of stroke and angina pectoris, limiting the conclusiveness of findings for these single endpoints. In adults with diabetes, comparisons of different RAS blockers showed similar effects of ACE inhibitors and ARBs on major cardiovascular and renal outcomes. Compared with monotherapies, the combination of an ACE inhibitor and an ARB failed to provide significant benefits on major outcomes.

According to the news editors, the research concluded: "Clinicians should discuss the balance between benefits, costs, and potential harms with individual diabetes patients before starting treatment."

The news editors report that additional information may be obtained by contacting F. Catala-Lopez, Dept. of Medicine, University of Valencia, INCLIVA Health Research Institute, Valencia, Spain. Additional authors for this research include D. Macias Saint-Gerons, D. Gonzalez-Bermejo, G.M. Rosano, B.R. Davis, M. Ridao, A. Zaragoza, D. Montero-Corominas, A. Tobias, C. de la Fuente-Honrubia, R. **Oncology - Pancreatic Cancer**

**Researchers at University of Verona Release New Data on Pancreatic Cancer (Percutaneous ablation of pancreatic cancer)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Oncology - Pancreatic Cancer have been published. According to news reporting originating from Verona, Italy, by NewsRx correspondents, research stated, "Pancreatic ductal adenocarcinoma is a highly aggressive tumor with an overall 5- year survival rate of less than 5%. Prognosis and treatment depend on whether
the tumor is resectable or not, which mostly depends on how quickly the diagnosis is made."

Our news editors obtained a quote from the research from the University of Verona, "Chemotherapy and radiotherapy can be both used in cases of non-resectable pancreatic cancer. In cases of pancreatic neoplasm that is locally advanced, non-resectable, but non-metastatic, it is possible to apply percutaneous treatments that are able to induce tumor cytoreduction."

According to the news editors, the research concluded: "The aim of this article will be to describe the multiple currently available treatment techniques (radiofrequency ablation, microwave ablation, cryoablation, and irreversible electroporation), their results, and their possible complications, with the aid of a literature review."

The news editors report that additional information may be obtained by contacting M. D'Onofrio, University of Verona, GB Rossi Hosp, Dept. of Radiol, I-37134 Verona, Italy. Additional authors for this research include V. Ciaravino, R. De Robertis, E. Barbi, R. Salvia, R. Girelli, S. Paiella, C. Gasparini, N. Cardobi and C. Bassi.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.3748/wjg.v22.i44.9661. This DOI is a link to an online electronic document that is either free or for purchase.

Oncology - Breast Cancer

Researchers at University of Vienna Report Findings in Breast Cancer (NF-kB contributes to MMP1 expression in breast cancer spheroids causing paracrine PAR1 activation and disintegrations in the lymph endothelial barrier in vitro)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Oncology - Breast Cancer is now available. According to news originating from Vienna, Austria, by NewsRx correspondents, research stated, "RELA, RELB, CREL, NF-kB1 and NF-kB2, and the upstream regulators NEMO and NIK were knocked-down in lymph endothelial cells (LECs) and in MDA-MB231 breast cancer spheroids to study the contribution of NF-kB in vascular barrier breaching. Suppression of RELA, NF-kB1 and NEMO inhibited 'circular chemo-repellent induced defects' (CCIDs), which form when cancer cells cross the lymphatic vasculature, by ~20-30%." Our news journalists obtained a quote from the research from the University of Vienna, "Suppression of RELB, NF-kB2 and NIK inhibited CCIDs by only ~10-15%. In MDA-MB231 cells RELA and NF-kB1 constituted MMP1 expression, which caused the activation of PAR1 in adjacent LECs. The knock-down of MMP1 in MDA-MB231 spheroids and pharmacological inhibition of PAR1 in LECs inhibited CCID formation by ~30%. Intracellular Ca(2+) release in LECs, which was induced by recombinant MMP1, was suppressed by the
PAR1 inhibitor SCH79797, thereby confirming a functional intercellular axis: RELA/NF-kB1 - MMP1 (MDA-MB231) - PAR1 (LEC). Recombinant MMP1 induced PAR1-dependent phosphorylation of MLC2 and FAK in LECs, which is indicative for their activity and for directional cell migration such as observed during CCID formation. The combined knock-down of the NF-kB pathways in LECs and MDA-MB231 spheroids inhibited CCIDs significantly stronger than knock-down in either cell type alone. Also the knock-down of ICAM-1 in LECs (a NF-kB endpoint with relevance for CCID formation) and knock-down of MMP1 in MDA-MB231 augmented CCID inhibition. This evidences that in both cell types NF-kB significantly and independently contributes to tumour-mediated breaching of the lymphatic barrier."

According to the news editors, the research concluded: "Hence, inflamed tumor tissue and/or vasculature pose an additional threat to cancer progression."

For more information on this research see: NF-kB contributes to MMP1 expression in breast cancer spheroids causing paracrine PAR1 activation and disintegrations in the lymph endothelial barrier in vitro. Oncotarget, 2015;6(36):39262-75.

**Lung Diseases and Conditions - Asthma**

**Researchers at University of Western Australia Detail Findings in Asthma (Rhinovirus-induced asthma exacerbations and risk populations)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Lung Diseases and Conditions - Asthma is now available. According to news reporting from Perth, Australia, by NewsRx journalists, research stated, "This article discusses recent findings into the mechanisms that determine how viruses trigger asthma exacerbations. Substantial progress has been made in our understanding of the pathogenesis of virus-induced asthma exacerbations."

The news correspondents obtained a quote from the research from the University of Western Australia, "This includes new insights into the role of bacteria, the regulation of interferon responses, and the discovery of innate immune pathways that link viral infections with allergic inflammation. Progress has also been made in elucidating the genetic risk factors for asthma exacerbations, most notably the contribution of the ORMDL3/GSDMB locus on 17q, the mechanisms underlying the farming effect, and the discovery that CDHR3 binds to rhinovirus species C. Asthma exacerbations are heterogeneous conditions that involve the complex interplay between environmental exposures and innate and adaptive immune function..."
in genetically predisposed individuals."

According to the news reporters, the research concluded: "Recent insights into the interrelationships between these factors provide new opportunities for therapeutic intervention."

For more information on this research see: Rhinovirus-induced asthma exacerbations and risk populations. *Current Opinion In Allergy and Clinical Immunology*, 2016;16(2):179-85. **Membrane Proteins - Ion Channels**

**Researchers at University of Western Australia Target Ion Channels (Evidence for redox sensing by a human cardiac calcium channel)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Membrane Proteins - Ion Channels. According to news originating from Crawley, Australia, by NewsRx correspondents, research stated, "Ion channels are critical to life and respond rapidly to stimuli to evoke physiological responses. Calcium influx into heart muscle occurs through the ion conducting α1C subunit (Cav1.2) of the L-type Ca(2+) channel."

Our news journalists obtained a quote from the research from the University of Western Australia, "Glutathionylation of Cav1.2 results in increased calcium influx and is evident in ischemic human heart. However controversy exists as to whether direct modification of Cav1.2 is responsible for altered function. We directly assessed the function of purified human Cav1.2 in proteoliposomes. Truncation of the C terminus and mutation of cysteines in the N terminal region and cytoplasmic loop III-IV linker did not alter the effects of thiol modifying agents on open probability of the channel. However mutation of cysteines in cytoplasmic loop I-II linker altered open probability and protein folding assessed by thermal shift assay. We find that C543 confers sensitivity of Cav1.2 to oxidative stress and is sufficient to modify channel function and posttranslational folding."

According to the news editors, the research concluded: "Our data provide direct evidence for the calcium channel as a redox sensor that facilitates rapid physiological responses."

For more information on this research see: Evidence for redox sensing by a human cardiac calcium channel. *Scientific Reports*, 2016;6():19067. (Nature Publishing Group -
Researchers at University of les Illes Balears Release New Data on Breast Cancer (The Phytoestrogen Genistein Affects Breast Cancer Cells Treatment Depending on the ERα/ERβ Ratio)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Oncology - Breast Cancer. According to news originating from Palma de Mallorca, Spain, by NewsRx correspondents, research stated, "Genistein (GEN) is a phytoestrogen found in soybeans. GEN exerts its functions through its interaction with the estrogen receptors (ER), ERα and ERβ, and we previously reported that the ERα/ERβ ratio is an important factor to consider in GEN-treated breast cancer cells."

Funders for this research include Fondo de Investigaciones Sanitarias of Instituto de Salud Carlos III, FEDER-Union Europea, Comunitat Autonoma de les Illes Balears, FEDER, Comunitat Autonoma de les Illes Balears cofinanced by Fondo Social Europeo.

Our news journalists obtained a quote from the research from the University of les Illes Balears, "The aim of this study was to investigate the effects of GEN in breast cancer cells with different ERα/ERβ ratio: MCF-7 (high ratio), T47D (low ratio), and MCF-7 overexpressing ERβ (MCF7 + ERβ) treated with cisplatin (CDDP), paclitaxel (PTX) or tamoxifen (TAM). Cell viability, ROS production, autophagy, apoptosis, antioxidant enzymes protein levels, and cell cycle were analyzed. GEN treatment provoked an increase in cell viability in MCF-7 cells and in the antioxidant enzymes protein levels in combination with the cytotoxic agents, decreasing ROS production (CDDP + GEN and TAM+GEN) and autophagy (TAM + GEN) or apoptosis (CDDP + GEN and TAM + GEN). Moreover GEN treatment enhanced the cell cycle S phase entry in CDDP+GEN-and TAM + GEN-treated MCF-7 cells and, in the case of CDDP + GEN, increased the proportion of cells in the G2/M phase and decreased it in the subG0/G1 phase. Otherwise, in the T47D and MCF7 + ERβ cells the combination of GEN with cytotoxic treatments did not cause significant changes in these parameters, even TAM + GEN-treated T47D cells showed less cell viability due to an increment in the autophagy."

According to the news editors, the research concluded: "GEN consumption may be counterproductive in those patients receiving anticancer treatment with a high ERα/ERβ ratio diagnosed breast cancer and it could be harmless or even beneficial in those patients with a lower ERα/ERβ ratio breast cancer cells."

For more information on this research see: The Phytoestrogen Genistein Affects

Endocrine Research

Researchers at Uppsala University Detail Findings in Endocrine Research (Progranulin Stimulates Proliferation of Mouse Pancreatic Islet Cells and Is Overexpressed in the Endocrine Pancreatic Tissue of an MEN1 Mouse Model)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Endocrine Research have been presented. According to news originating from Uppsala, Sweden, by NewsRx correspondents, research stated, "Progranulin (PGRN) promotes cell growth and cell cycle progression in several cell types and contributes to tumorigenesis in diverse cancers. We have recently reported PGRN expression in islets and tumors developed in an MEN1 transgenic mouse."

Our news journalists obtained a quote from the research from Uppsala University, "Here we sought to investigate PGRN expression and regulation after exposure to hypoxia as well as its effects on pancreatic islet cells and neuroendocrine tumors (NETs) in MEN1 ((plusminus)) mice. Gene and protein expression were analyzed by quantitative polymerase chain reaction, immunohistochemistry, and Western blot. We also investigated PGRN expression in samples from patients carrying pancreatic NETs associated or not with the multiple endocrine neoplasia 1 syndrome, using enzyme-linked immunosorbent assay and immunohistochemistry analysis. Progranulin is upregulated in tumors and islets of the MEN1 mouse as well as in the serum of patients with pancreatic NETs associated with glucagonoma syndrome. In normal mice islets and pancreatic tumors, PGRN expression was strongly potentiated by hypoxia. Progranulin promotes cell proliferation in islet cells and bTC-6 cells, a process paralleled by activation of the mitogen-activated protein kinase signaling cascade."

According to the news editors, the research concluded: "Our findings identify PGRN as an effective inducer of pancreatic islet cell proliferation and a possible important factor for pancreatic endocrine tumor development."

For more information on this research see: Progranulin Stimulates Proliferation of Mouse Pancreatic Islet Cells and Is Overexpressed in the Endocrine Pancreatic Tissue of an MEN1 Mouse Model. *Pancreas*, 2016;45(4):533-40. (Lippincott Williams and Wilkins -
Researchers at Upstate Medical University Have Reported New Data on Allergies (Impact of a pharmacist-driven beta-lactam allergy interview on inpatient antimicrobial therapy: A pilot project)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Immune System Diseases and Conditions - Allergies are discussed in a new report. According to news reporting from Syracuse, New York, by NewsRx journalists, research stated, "To determine the impact of a pharmacist-driven beta-lactam allergy interview on antimicrobial therapy. Tertiary care academic medical center."

The news correspondents obtained a quote from the research from Upstate Medical University, "Practice setting: Clarification of beta-lactam allergy may expand treatment options for patients and potentially improve outcomes, reduce toxicity, and reduce costs. Practice innovation: At our institution, a pilot service using a pharmacy resident and infectious diseases clinical pharmacist was implemented to clarify beta-lactam allergy information and, where appropriate, recommend a change to the patient's antibiotic therapy. Evaluation: Adult patients with a documented beta-lactam allergy who had received non-penicillin antibiotics and who had undergone a beta-lactam allergy interview were identified via pharmacy intervention data. A pharmacist interviewed these patients with the use of an internally developed allergy questionnaire. Recommendations for beta-lactam therapy were made to the patient's primary medical team based on the results of the allergy interview and factors including infection type and culture results. The primary objectives were to determine the percentage of patients successfully switched to beta-lactam therapy as a result of the drug allergy interview, to identify allergy discrepancies between the electronic medical record (EMR) and pharmacist's interview, and to quantify the acceptance rate of the pharmacist's antimicrobial recommendations after drug allergy clarification. Thirty-two patients were interviewed, and 24 were candidates for a beta-lactam recommendation. As a result of the interview, 21 patients (65.6%) were successfully switched from a non-penicillin antibiotic to a cephalosporin, carbapenem, or penicillin. A discrepancy between the EMR-reported allergy and history obtained on interview was identified in 11 patients (34.4%). Medical providers accepted 87.5% of pharmacists' antimicrobial recommendations. A pharmacist-driven beta-lactam allergy interview was effective in switching eligible patients to beta-lactam therapy and identifying discrepancies between EMR-documented allergies and confirmed allergies."
According to the news reporters, the research concluded: "Antimicrobial recommendations were well received by medical providers with a high acceptance rate."

Our news journalists report that additional information may be obtained by contacting J.M. Steele, Upstate Med Univ, Dept. of Med, Med, Syracuse, NY, United States. Additional authors for this research include J.M. Steele and C.D. Miller.

Immunization - Vaccines

Researchers at Vaccine and Gene Therapy Institute Release New Data on Vaccines (Pre-vaccination inflammation and B-cell signalling predict age-related hyporesponse to hepatitis B vaccination)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Immunization - Vaccines are presented in a new report. According to news reporting originating from Port St. Lucie, Florida, by NewsRx correspondents, research stated, "Aging is associated with hyporesponse to vaccination, whose mechanisms remain unclear. In this study hepatitis B virus (HBV)-naive older adults received three vaccines, including one against HBV."

Our news editors obtained a quote from the research from Vaccine and Gene Therapy Institute, "Here we show, using transcriptional and cytometric profiling of whole blood collected before vaccination, that heightened expression of genes that augment B-cell responses and higher memory B-cell frequencies correlate with stronger responses to HBV vaccine. In contrast, higher levels of inflammatory response transcripts and increased frequencies of pro-inflammatory innate cells correlate with weaker responses to this vaccine. Increased numbers of erythrocytes and the haem-induced response also correlate with poor response to the HBV vaccine. A transcriptomics-based pre-vaccination predictor of response to HBV vaccine is built and validated in distinct sets of older adults. This moderately accurate (area under the curve&asymp;65%) but robust signature is supported by flow cytometry and cytokine profiling."

According to the news editors, the research concluded: "This study is the first that identifies baseline predictors and mechanisms of response to the HBV vaccine."

For more information on this research see: Pre-vaccination inflammation and B-cell signalling predict age-related hyporesponse to hepatitis B vaccination. Nature Communications, 2016;7():10369. (Nature Publishing Group - www.nature.com/; Nature Communications - www.nature.com/ncomms/)

Researchers at Vanderbilt University Discuss Findings in Venous Thromboembolism (Venous thromboembolism in hematopoietic stem cell transplant recipients)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Cardiovascular Diseases and Conditions - Venous Thromboembolism. According to news reporting from Nashville, Tennessee, by NewsRx journalists, research stated, "Venous thromboembolism (VTE) is an increasingly recognized problem in the post-hematopoietic stem cell transplantation (HSCT) setting, with a lack of high-quality evidence-based data to recommend best practices. Few patients with hematologic malignancies and even fewer post-HSCT patients were included in randomized trials of VTE prophylaxis and treatment."

The news correspondents obtained a quote from the research from Vanderbilt University, "Prior VTE, GVHD, infections and indwelling venous catheters are risk factors for thrombosis. The increasing use of post-transplant maintenance therapy with lenalidomide in patients with multiple myeloma adds to this risk after autologous HSCT. These patients are also at high risk of bleeding complications because of prolonged thrombocytopenia and managing the competing risks of bleeding and thrombosis can be challenging."

According to the news reporters, the research concluded: "This review aims to provide a practical, clinician-focused approach to the prevention and treatment of VTE in the post-HSCT setting."

For more information on this research see: Venous thromboembolism in hematopoietic stem cell transplant recipients. *Bone Marrow Transplantation*, 2015;51(4):473-8. *Bone Marrow Transplantation* can be contacted at: Nature Publishing Group, 345 Park Avenue South, New York, NY 10010-1707, USA. (Nature Publishing Group - www.nature.com/; Bone Marrow Transplantation - www.nature.com/bmt/)

Our news journalists report that additional information may be obtained by contacting S. Chaturvedi, Hematology and Stem Cell Transplantation Section, Division of Hematology, Oncology, Dept. of Medicine, Vanderbilt University Medical Center and Veterans Affairs Medical Center, Nashville, TN, United States. Additional authors for this research include A. Neff, A. Nagler, U. Savani, M. Mohty and B.N Savani.
Researchers at Vanderbilt University Have Reported New Data on Cancer Risk (Pathogenic Helicobacter pylori strains translocate DNA and activate TLR9 via the cancer-associated cag type IV secretion system)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Oncology-Cancer Risk. According to news reporting from Nashville, Tennessee, by NewsRx journalists, research stated, "Helicobacter pylori (H. pylori) is the strongest identified risk factor for gastric cancer, the third most common cause of cancer-related death worldwide. An H. pylori constituent that augments cancer risk is the strain-specific cag pathogenicity island, which encodes a type IV secretion system (T4SS) that translocates a pro-inflammatory and oncogenic protein, CagA, into epithelial cells. However, the majority of persons colonized with CagA+ H. pylori strains do not develop cancer, suggesting that other microbial effectors also have a role in carcinogenesis."

The news correspondents obtained a quote from the research from Vanderbilt University, "Toll-like receptor 9 (TLR9) is an endosome bound, innate immune receptor that detects and responds to hypo-methylated CpG DNA motifs that are most commonly found in microbial genomes. High-expression tlr9 polymorphisms have been linked to the development of premalignant lesions in the stomach. We now demonstrate that levels of H. pylori-mediated TLR9 activation and expression are directly related to gastric cancer risk in human populations. Mechanistically, we show for the first time that the H. pylori cancer-associated cag T4SS is required for TLR9 activation and that H. pylori DNA is actively translocated by the cag T4SS to engage this host receptor. Activation of TLR9 occurs through a contact-dependent mechanism between pathogen and host, and involves transfer of microbial DNA that is both protected as well as exposed during transport."

According to the news reporters, the research concluded: "These results indicate that TLR9 activation via the cag island may modify the risk for malignancy within the context of H. pylori infection and provide an important framework for future studies investigating the microbial-epithelial interface in gastric carcinogenesis."

For more information on this research see: Pathogenic Helicobacter pylori strains translocate DNA and activate TLR9 via the cancer-associated cag type IV secretion system. Oncogene, 2016;35(48):6262-6269. Oncogene can be contacted at: Nature Publishing Group, Macmillan Building, 4 Crinan St, London N1 9XW, England. (Nature Publishing Group -...
Researchers at Vanderbilt University Have Reported New Data on Genetics (Heterozygosity Ratio, a Robust Global Genomic Measure of Autozygosity and Its Association with Height and Disease Risk)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Life Science Research - Genetics. According to news reporting originating in Nashville, Tennessee, by NewsRx journalists, research stated, "Greater genetic variability in an individual is protective against recessive disease. However, existing quantifications of autozygosity, such as runs of homozygosity (ROH), have proved highly sensitive to genotyping density and have yielded inconclusive results about the relationship of diversity and disease risk."

The news reporters obtained a quote from the research from Vanderbilt University, "Using genotyping data from three data sets with >43,000 subjects, we demonstrated that an alternative approach to quantifying genetic variability, the heterozygosity ratio, is a robust measure of diversity and is positively associated with the nondisease trait height and several disease phenotypes in subjects of European ancestry. The heterozygosity ratio is the number of heterozygous sites in an individual divided by the number of nonreference homozygous sites and is strongly affected by the degree of genetic admixture of the population and varies across human populations. Unlike quantifications of ROH, the heterozygosity ratio is not sensitive to the density of genotyping performed."

According to the news reporters, the research concluded: "Our results establish the heterozygosity ratio as a powerful new statistic for exploring the patterns and phenotypic effects of different levels of genetic variation in populations."

For more information on this research see: Heterozygosity Ratio, a Robust Global Genomic Measure of Autozygosity and Its Association with Height and Disease Risk. Genetics, 2016;204(3):893-904,17-25. Researchers at Vanderbilt University Target Hypertension [Redox biology in pulmonary arterial hypertension (2013 Grover Conference Series)]

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Cardiovascular Diseases and Conditions - Hypertension. According to news reporting from Nashville, Tennessee, by NewsRx journalists, research stated, "Through detailed interrogation of the molecular pathways that contribute to the development of pulmonary arterial hypertension (PAH), the separate but related processes of oxidative stress and cellular metabolic dysfunction have emerged as being critical pathogenic mechanisms that are as yet relatively untargeted therapeutically. In this review, we have attempted to summarize some of the important existing studies, to point out areas of overlap between oxidative stress and metabolic dysfunction, and to do so under the unifying heading of redox biology."

The news correspondents obtained a quote from the research from Vanderbilt University, "We discuss the importance of precision in assessing oxidant signaling versus oxidant injury and why this distinction matters. We endeavor to advance the discussion of carbon-substrate metabolism beyond a focus on glucose and its fate in the cell to encompass other carbon substrates and some of the murkiness surrounding our understanding of how they are handled in different cell types. Finally, we try to bring these ideas together at the level of the mitochondrion and to point out some additional points of possible cognitive dissonance that warrant further experimental probing. The body of beautiful science regarding the molecular and cellular details of redox biology in PAH points to a future that includes clinically useful therapies that target these pathways."

According to the news reporters, the research concluded: "To fully realize the potential of these future interventions, we hope that some of the issues raised in this review can be addressed proactively."

Our news journalists report that additional information may be obtained by contacting J.P. Fessel, Division of Allergy, Pulmonary and Critical Care Medicine, Dept. of
Researchers at Vikram University Release New Data on Colon Cancer (Study of apoptosis-related interactions in colorectal cancer)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Oncology - Colon Cancer. According to news reporting from Ujjain, India, by NewsRx journalists, research stated, "Abnormalities in apoptotic functions contribute to the pathogenesis of colorectal cancer. In this study, molecular interactions behind the apoptotic regulation have been explored."

Financial support for this research came from University Grants Commission. The news correspondents obtained a quote from the research from Vikram University, "For this purpose, enrichment analysis was performed considering microRNAs (miRNAs) that putatively target TP53 and altered during colon cancer. This revealed gene associated with both TP53 and miRNAs. Further analysis showed that a significant molecular interaction between the shortlisted candidates (TP53, miR-143, KRAS, BCL2, and PLK1) exists. Mutation study was conducted to confirm the clinical relevance of candidates. It showed that the mutation extent does not significantly alter survival in patients thus making these candidates suitable as drug targets."

According to the news reporters, the research concluded: "Overall, we showed the importance of interactions between TP53, miR-143, KRAS, BCL2, and PLK1 with respect to colorectal cancer using bioinformatics approach."

For more information on this research see: Study of apoptosis-related interactions in colorectal cancer. Tumor Biology, 2016;37(11):14415-14425. Tumor Biology can be contacted at: Springer, Van Godewijckstraat 30, 3311 Gz Dordrecht, Netherlands. (Springer - www.springer.com; Tumor Biology - www.springerlink.com/content/1010-4283/)

Researchers at Washington University Have Reported New Data on Obesity (Provider Training to Screen and Initiate Evidence-Based Pediatric Obesity Treatment in Routine Practice Settings: A Randomized Pilot Trial)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Nutritional and Metabolic Diseases and Conditions - Obesity are presented in a new report. According to news reporting originating from St. Louis, Missouri, by NewsRx correspondents, research stated, "This randomized pilot trial evaluated two training modalities for first-line, evidence-based pediatric obesity services (screening and goal setting) among nursing students. Participants (N = 63) were randomized to live interactive training or Web-facilitated self-study training."

Our news editors obtained a quote from the research from Washington University, "Pretraining, post-training, and 1-month follow-up assessments evaluated training feasibility, acceptability, and impact (knowledge and skill via simulation). Moderator (previous experience) and predictor (content engagement) analyses were conducted. Nearly all participants (98%) completed assessments. Both types of training were acceptable, with higher ratings for live training and participants with previous experience (ps <.05). Knowledge and skill improved from pretraining to post-training and follow-up in both conditions (ps <.001). Live training demonstrated greater content engagement (p <.01). The training package was feasible, acceptable, and efficacious among nursing students."

According to the news editors, the research concluded: "Given that live training had higher acceptability and engagement and online training offers greater scalability, integrating interactive live training components within Web-based training may optimize outcomes, which may enhance practitioners' delivery of pediatric obesity services."

The news editors report that additional information may be obtained by contacting R.P. Kolko, Washington University, Dept. of Psychol, St Louis, MO 63130, United States. Additional authors for this research include A.E. Kass, J.F. Hayes, M.D. Levine, J.M. Garbutt, E.K. Proctor and D.E. Wilfley.

Researchers at Washington University Target Staphylococcus aureus (Impact of Time to Appropriate Therapy on Mortality in Patients with Vancomycin-Intermediate Staphylococcus aureus Infection)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Gram-Positive Bacteria - Staphylococcus aureus have been published. According to news reporting out of St. Louis, Missouri, by NewsRx editors, research stated, "Despite the increasing incidence of vancomycin-intermediate Staphylococcus aureus (VISA) infections, few studies have examined the impact of delay in receipt of appropriate antimicrobial therapy on outcomes in VISA patients. We examined the effects of timing of appropriate antimicrobial therapy in a cohort of patients with sterile-site methicillin-resistant S. aureus (MRSA) and VISA infections."

Our news journalists obtained a quote from the research from Washington University, "In this single-center, retrospective cohort study, we identified all patients with MRSA or VISA sterile-site infections from June 2009 to February 2015. Clinical outcomes were compared according to MRSA/VISA classification, demo-graphics, comorbidities, and antimicrobial treatment. Thirty-day all-cause mortality was modeled with Kaplan-Meier curves. Multivariate logistic regression analysis (MVLRA) was used to determine odds ratios for mortality. We identified 354 patients with MRSA (n = 267) or VISA (n = 87) sterile-site infection. Fifty-five patients (15.5%) were nonsurvivors. Factors associated with mortality in MVLRA included pneumonia, unknown source of infection, acute physiology and chronic health evaluation (APACHE) II score, solid-organ malignancy, and admission from skilled care facilities. Time to appropriate antimicrobial therapy was not significantly associated with outcome. Presence of a VISA infection compared to that of a non-VISA S. aureus infection did not result in excess mortality. Linezolid use was a risk for mortality in patients with APACHE II scores of >= 14. Our results suggest that empirical vancomycin use in patients with VISA infections does not result in excess mortality."

According to the news editors, the research concluded: "Future studies should (i) include larger numbers of patients with VISA infections to confirm the findings presented here and (ii) determine the optimal antibiotic therapy for critically ill patients with MRSA and VISA infections."

For more information on this research see: Impact of Time to Appropriate Therapy on Mortality in Patients with Vancomycin-Intermediate Staphylococcus aureus Infection. Antimicrobial Agents and Chemotherapy, 2016;60(9):5546-5553. Antimicrobial Agents and Chemotherapy can be contacted at: Amer Soc Microbiology, 1752 N St NW, Washington, DC 20036-2904, USA. Life Science Research - Molecular and Cellular Biology

Researchers at Wuhan University Release New Data on Molecular and Cellular Biology (Polo-like Kinase-1 Regulates Myc Stabilization and Activates a Feedforward Circuit Promoting Tumor Cell Survival)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Life Science Research - Molecular and Cellular Biology is now available. According to news reporting out of Wuhan, People's Republic of China, by NewsRx editors, research stated, "MYCN amplification in human cancers predicts poor prognosis and resistance to therapy. However, pharmacological strategies that directly target N-Myc, the protein encoded by MYCN, remain elusive."

Our news journalists obtained a quote from the research from Wuhan University, "Here, we identify a molecular mechanism responsible for reciprocal activation between Polo-like kinase-1 (PLK1) and N-Myc. PLK1 specifically binds to the SCF Fbw7 ubiquitin ligase, phosphorylates it, and promotes its autopolyubiquitination and proteasomal degradation, counteracting Fbw7-mediated degradation of N-Myc and additional substrates, including cyclin E and Mcl1. Stabilized N-Myc in turn directly activates PLK1 transcription, constituting a positive feedforward regulatory loop that reinforces Myc-regulated oncogenic programs. Inhibitors of PLK1 preferentially induce potent apoptosis of MYCN-amplified tumor cells from neuroblastoma and small cell lung cancer and synergistically potentiate the therapeutic efficacies of Bcl2 antagonists."

According to the news editors, the research concluded: "These findings reveal a PLK1-Fbw7-Myc signaling circuit that underlies tumorigenesis and validate PLK1 inhibitors, alone or with Bcl2 antagonists, as potential effective therapeutics for MYC-overexpressing cancers."

For more information on this research see: Polo-like Kinase-1 Regulates Myc Stabilization and Activates a Feedforward Circuit Promoting Tumor Cell Survival. Molecular Cell, 2016;64(3):493-506. Molecular Cell can be contacted at: Cell Press, 600 Technology Square, 5TH Floor, Cambridge, MA 02139, USA. (Elsevier - www.elsevier.com; Molecular Cell - www.journals.elsevier.com/molecular-cell/)

Researchers at Yale University School of Medicine Describe Findings in Type 2 Diabetes (Metabolic syndrome: genetic insights into disease pathogenesis)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Nutritional and Metabolic Diseases and Conditions - Type 2 Diabetes. According to news reporting from New Haven, Connecticut, by NewsRx journalists, research stated, "Metabolic syndrome (MetS) is a cluster of interrelated and heritable metabolic traits, which collectively impart unsurpassed risk for atherosclerotic cardiovascular disease and type 2 diabetes. Considerable work has been done to understand the underlying disease mechanisms by elucidating its genetic cause."

The news correspondents obtained a quote from the research from the Yale University School of Medicine, "Genome-wide association studies have been widely utilized albeit with modest success in identifying variants that are associated with more than two metabolic traits. Another limitation of this approach is the inherent small effect of the common variants, a major barrier for dissecting their cognate pathways. Modest advances in this venue have been also made by genetic studies of kindreds at the extreme ends of quantitative distributions. These efforts have led to the discovery of a number of disease genes with large effects that underlie the association of diverse traits of this syndrome. Substantial progress has been made over the last decade in identification of genetic risk factors associated with the various traits of MetS. The heterogeneity and multifactorial heritability of MetS, however, has been a challenge toward understanding the factors underlying the association of these traits."

According to the news reporters, the research concluded: "Genetic investigations of outlier kindreds or homogenous populations with high prevalence for the disease can potentially improve our knowledge of the disease pathophysiology."

For more information on this research see: Metabolic syndrome: genetic insights into disease pathogenesis. Current Opinion In Lipidology, 2016;27(2):162-71. (Lippincott Williams and Wilkins - www.lww.com; Current Opinion In Lipidology - journals.lww.com/co-lipidology/pages/default.aspx)

Researchers at Yokohama City University Graduate School of Medicine Report Findings in Bladder Cancer (Expression of androgen receptor in non-muscle-invasive bladder cancer predicts the preventive effect of androgen deprivation therapy on tumor ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Oncology - Bladder Cancer are presented in a new report. According to news originating from Yokohama, Japan, by NewsRx correspondents, research stated, "Our recent retrospective study revealed a significantly reduced risk of bladder cancer (BC) recurrence in men who received androgen deprivation therapy (ADT) for their prostate cancer. However, whether androgen receptor (AR) signals contributed to the preventive effect of ADT remained unclear because ADT could reduce serum estrogens as well."

Our news journalists obtained a quote from the research from the Yokohama City University Graduate School of Medicine, "The purpose of this study is to investigate the associations between the expression of AR/estrogen receptors (ERs) and BC recurrence in patients treated with ADT. We immunohistochemically stained 72 BCs and 42 corresponding normal urothelial tissues. AR/ERa/ERb were positive in 44(61%)/22(31%)/39(54%) tumors and 35(83%)/24(57%)/34(81%) corresponding normal urothelial tissues, respectively. There were no statistically significant correlations between AR/ERa/ERb expression and clinicopathological features of BC. With a median follow-up of 31.3 months, 12 (43%) of 28 patients with AR-negative tumor versus 11 (23%) of 44 patients with AR-positive tumor experienced BC recurrence. Thus, patients with AR-positive tumor had a significantly lower risk of BC recurrence (p=0.031), compared with those with AR-negative tumor. Meanwhile, the expression of ERa/ERb in tumors and that of AR/ERa/ERb in normal urothelial tissues were not significantly correlated with BC recurrence. A multivariate analysis revealed AR positivity in tumors as an independent prognosticator (hazard ratio: 0.27; 95% confidence interval: 0.11-0.67) for BC recurrence."

According to the news editors, the research concluded: "These results indicate that ADT prevents BC recurrence via the AR pathway, but not via the ERa/ERb pathways."

For more information on this research see: Expression of androgen receptor in non-muscle-invasive bladder cancer predicts the preventive effect of androgen deprivation therapy on tumor recurrence. Oncotarget, 2016;7(12):14153-60.

The news correspondents report that additional information may be obtained from K. Izumi, Dept. of Urology, Yokohama City University Graduate School of Medicine, Yokohama, Japan. Researchers at Yokohama City University Graduate School of Medicine Target Small Cell Lung Cancer (Amrubicin for relapsed small-cell lung cancer: a systematic review and meta-analysis of 803 patients)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Oncology - Small Cell Lung Cancer have been published. According to news reporting originating from Yokohama, Japan, by NewsRx correspondents, research stated, "Currently, amrubicin is permitted for relapsed small-cell lung carcinoma (SCLC) only in Japan. The efficacy and adverse effects of amrubicin as reported by previous studies varied greatly."

Our news editors obtained a quote from the research from the Yokohama City University Graduate School of Medicine, "The inclusion criterion was a prospective study that was able to provide data for efficacy and safety by the AMR single agent regimen as second-line chemotherapy for a patient with SCLC. Binary data were meta-analyzed with the random-model generic inverse variance method. We included nine articles consisted of 803 patients. The pooled three-, six-, and nine-month progression-free survival were 63% (95% CI 57-69%, I(2)=53%), 28% (95% CI 21-35%, I(2)=71%), and 10% (95% CI 6-14%, I(2)=41%), respectively. The pooled six-, 12-, and 18-month overall survival were 69% (95% CI 61-78%, I(2)=83%), 36% (95% CI 28-44%, I(2)=80%), and 15% (95% CI 8-21%, I(2)=81%), respectively. Amrubicin seemed much more beneficial for Japanese patients. However, compared to the efficacy of topotecan presented in a previous meta-analysis, amrubicin may be a better treatment option than topotecan for both Japanese and Euro-American. Adverse effects by amrubicin were almost exclusively observed to be hematological."

According to the news editors, the research concluded: "Notably, grade III/IV neutropenia incidence was 70% and febrile neutropenia incidence was 12%."

For more information on this research see: Amrubicin for relapsed small-cell lung cancer: a systematic review and meta-analysis of 803 patients. Scientific Reports, 2016;6 ():18999. (Nature Publishing Group - www.nature.com/; Scientific Reports - www.nature.com/srep/)

Researchers at Zhejiang University Have Reported New Data on Regenerative Medicine (Coating with spermine-pullulan polymer enhances adenoviral transduction of mesenchymal stem cells)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Biomedical Engineering - Regenerative Medicine are presented in a new report. According to news reporting out of Hangzhou, People's Republic of China, by NewsRx editors, research stated, "Mesenchymal stem cells (MSCs) are adult stem cells with multilineage potential, which makes them attractive tools for regenerative medicine applications. Efficient gene transfer into MSCs is essential not only for basic research in developmental biology but also for therapeutic applications involving gene-modification in regenerative medicine."

Our news journalists obtained a quote from the research from Zhejiang University, "Adenovirus vectors (Advs) can efficiently and transiently introduce an exogenous gene into many cell types via their primary receptors, the coxsackievirus and adenovirus receptors, but not into MSCs, which are deficient in coxsackievirus and adenovirus receptors expression. To overcome this problem, we developed an Adv coated with a spermine-pullulan (SP) cationic polymer and investigated its physicochemical properties and internalization mechanisms. We demonstrated that the SP coating could enhance adenoviral transduction of MSCs without detectable cytotoxicity or effects on differentiation."

According to the news editors, the research concluded: "Our results argue in favor of the potentiality of the SP-coated Adv as a prototype vector for efficient and safe transduction of MSCs."

For more information on this research see: Coating with spermine-pullulan polymer enhances adenoviral transduction of mesenchymal stem cells. International Journal of Nanomedicine, 2016;11():6763-6769. International Journal of Nanomedicine can be contacted at: Dove Medical Press Ltd, PO Box 300-008, Albany, Auckland 0752, New Zealand.

Researchers at Zhejiang University School of Medicine Target Viral RNA (Bcl6 Sets a Threshold for Antiviral Signaling by Restraining IRF7 Transcriptional Program)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Viral RNA. According to news reporting from Hangzhou, People's Republic of China, by NewsRx journalists, research stated, "The coordination of restraining and priming of antiviral signaling constitute a fundamental aspect of immunological functions. However, we currently know little about the molecular events that can translate the pathogenic cues into the appropriate code for antiviral defense."

The news correspondents obtained a quote from the research from the Zhejiang University School of Medicine, "Our present study reports a specific role of B cell lymphoma (Bcl)6 as a checkpoint in the initiation of the host response to cytosolic RNA viruses. Remarkably, Bcl6 specifically binds to the interferon-regulatory factor (IRF)7 loci and restrains its transcription, thereby functioning as a negative regulator for interferon (IFN)-b production and antiviral responses. The signal-controlled turnover of the Bcl6, most likely mediated by microRNA-127, coordinates the antiviral response and inflammatory sequelae. Accordingly, de-repression of Bcl6 resulted in a phenotypic conversion of macrophages into highly potent IFN-producing cells and rendered mice more resistant to pathogenic RNA virus infection. The failure to remove the Bcl6 regulator, however, impedes the antiviral signaling and exaggerates viral pneumonia in mice."

According to the news reporters, the research concluded: "We thus reveal a novel key molecular checkpoint to orchestrate antiviral innate immunity."

For more information on this research see: Bcl6 Sets a Threshold for Antiviral Signaling by Restraining IRF7 Transcriptional Program. Scientific Reports, 2016;6():18778. (Nature Publishing Group - www.nature.com/; Scientific Reports - www.nature.com/srep/)

Our news journalists report that additional information may be obtained by contacting F. Researchers from ANSES Detail New Studies and Findings in the Area of Escherichia coli [Sequence Type 48 Escherichia coli Carrying the bla (CTX-M-1) IncI1/ST3 Plasmid in Drinking Water in France]

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Gram-Negative Bacteria - Escherichia coli is the subject of a report. According to news reporting from Lyon, France, by NewsRx journalists, research stated, "Drinking water has rarely been recognized as a source of antimicrobial resistance for humans, and only in low-income countries."

The news correspondents obtained a quote from the research from ANSES, "Here, a sequence type 48 Escherichia coli isolate carrying the bla(CTX-M-1) IncI1/ST3 plasmid was recovered from drinking water in France. This plasmid was similar to other bla(CTX-M-1) IncI1/ST3 plasmids found previously in animals and humans."

According to the news reporters, the research concluded: "Our findings highlight the possible human transfer of extended-spectrum beta-lactamase (ESBL) genes through drinking water in high-income countries."

For more information on this research see: Sequence Type 48 Escherichia coli Carrying the bla(CTX-M-1) IncI1/ST3 Plasmid in Drinking Water in France. Antimicrobial Agents and Chemotherapy, 2016;60(10):6430-6432. Antimicrobial Agents and Chemotherapy can be contacted at: Amer Soc Microbiology, 1752 N St NW, Washington, DC 20036-2904, USA. Nursing - Clinical Nursing

Researchers from AUT University Discuss Findings in Clinical Nursing
(The condom imperative in anal sex - one size may not fit all: a qualitative descriptive study of men who have sex with men)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Nursing - Clinical Nursing have been published. According to news reporting originating in Auckland, New Zealand, by NewsRx journalists, research stated, "Aims and objectives. To explore men who have sex with men's views about condom use when having anal intercourse."

Financial support for this research came from Ministry of Health.

The news reporters obtained a quote from the research from AUT University,
"Internationally, health promotion campaigns use behavioural change strategies to support men who have sex with men to always use condoms when having anal sex with other men. The health promotion message given to this group is consistent and explicitly stated that 'use a condom every time for anal sex regardless of relationship status'. Qualitative analysis of data from a cohort of New Zealand men who have sex with men. A total of 960 useable questionnaires were completed: 571 online and 389 in hard copy. Qualitative data were analysed using a thematic data analytic process. Three themes relating to condom use in men who have sex with men were identified. These are as follows: 'Safer sex is good sex', 'Condom use is good but ...' and 'I use condoms sometimes'. The range of responses towards condom use for anal sex in men who have sex with men in our sample reveal this as a complex public health issue, with not all men who have sex with men willing to consistently use condoms. Relevance to clinical practice. It is important that nurses do not assume that all men who have sex with men are willing to use condoms for anal sex, and should create opportunities for men who have sex with men to raise any concerns about the use of condoms."

According to the news reporters, the research concluded: "In this way, nurses can assist in providing information that may help men who have sex with men to make decisions that will minimise risk of contracting infections associated with sexual activity."

Our news correspondents report that additional information may be obtained by contacting S. Neville, AUT Univ, Dept. of Nursing, Auckland, New Zealand. Additional authors for this research include J. Adams, C. Moorley and D. Jackson.

Heart Disorders and Diseases - Heart Failure

Researchers from Aarhus University Detail Findings in Heart Failure (A rare presentation of cardiac amyloid deposits isolated to intramural vessels)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Heart Disorders and Diseases - Heart Failure have been published. According to news reporting out of Aarhus, Denmark, by NewsRx editors, research stated, "The present case illustrates the diagnostic challenges in symptomatic patients with heart failure of unknown etiology. The patients were previously diagnosed with -light chain amyloidosis without cardiac involvement."

Our news journalists obtained a quote from the research from Aarhus University,
"Echocardiography showed heart failure with mildly reduced ejection fraction but no signs of amyloidosis. Coronary angiogram showed normal arteries and 11C-PIB positron emission tomography was negative for amyloid deposits. Exercise testing revealed severe heart failure and reduced coronary flow velocity reserve. Endomyocardial biopsies showed amyloid in the intramural coronary arteries without interstitial amyloid deposits."

According to the news editors, the research concluded: "Hence, the patient was diagnosed with microvascular dysfunction-induced heart failure due to vessel wall amyloidosis."

Our news journalists report that additional information may be obtained by contacting T.S. Clemmensen, Aarhus University, Dept. of Cardiol, Aarhus N, Denmark. Additional authors for this research include H. Molgaard, N.F. Andersen, S. Baerentzen, J. Soerensen and S.H. Poulsen.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1111/echo.13365. This DOI is a link to an online electronic document that is either free or for purchase.

Cardiology

Researchers from Aarhus University Hospital Report Recent Findings in Cardiology (Relocation of patients after cardiac surgery: is it worth the effort?)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Cardiology. According to news reporting out of Aarhus, Denmark, by NewsRx editors, research stated, "Fast-track protocols may facilitate early patient discharge from the site of surgery through the implementation of more expedient pathways. However, costs may merely be shifted towards other parts of the health care system."

Our news journalists obtained a quote from the research from Aarhus University Hospital, "We aimed to investigate the consequence of patient transfers on overall hospitalisation, follow-up and readmission rate after cardiac surgery. A single-centre descriptive cohort study using prospectively entered registry data. The study included 4,515 patients who underwent cardiac surgery at Aarhus University Hospital during the period 1 April 2006 to 31 December 2012. Patients were grouped and analysed based on type of discharge: Directly from site of surgery or after transfer to a regional hospital. The cohort was obtained from the Western Denmark Heart Registry and matched to the Danish National Hospital Register. Median overall length of stay was 9 days (7.0;14.4). Transferred patients had longer length of stay, median
difference of 2.0 days, p<0.001. Time to first outpatient consultation was 41(30;58) days in transferred patients vs. 45(29;74) days, p<0.001. 18.6% was readmitted within 30 days. Mean time to readmission was 18.4 ? 6.4 days. Median length of readmission was 3(1,6) days. There was no difference in readmissions between groups. Leading cause of readmission was cardiovascular disease with 48%. Transfer of patients does not overtly reduce health care costs, but overall LOS and time to first outpatient consultation are substantially longer in patients transferred to secondary hospitals than in patients discharged directly."

According to the news editors, the research concluded: "Readmission rate is high during the month after surgery, but with no difference between groups."

Our news journalists report that additional information may be obtained by contacting L.S. Hansen, Dept. of Anaesthesiology and Intensive Care, Aarhus University Hospital, Aarhus N, Denmark. Additional authors for this research include V.E. Hjortdal and C.J Jakobsen.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1111/aas.12679. This DOI is a link to an online electronic document that is either free or for purchase.

Oncology - Prostate Cancer

Researchers from Addenbrooke's Hospital Report Findings in Prostate Cancer (Multiparametric Prostate Magnetic Resonance Imaging and Cognitively Targeted Transperineal Biopsy in Patients With Previous Abdominoperineal Resection and Suspicion of ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Oncology - Prostate Cancer is now available. According to news reporting originating in Cambridge, United Kingdom, by NewsRx journalists, research stated, "To report our experience with a combination of prostate magnetic resonance imaging (MRI) and transperineal ultrasound biopsy for evaluating the prostate in patients with elevated prostate specific antigen (PSA) who have previously undergone abdominoperineal resection (APR). We reviewed the records of 11 patients with a history of APR and clinical suspicion of prostate cancer due to elevated PSA levels over a 5-year period."

The news reporters obtained a quote from the research from Addenbrooke's Hospital, "All patients underwent multiparametric MRI at our institution prior to biopsy. MR diagnoses were validated either by transperineal ultrasound biopsy (Likert 3-5) guided by visual registration or clinical follow-up >6 months (Likert 1-2). All 7 cases with highly suspicious lesions (Likert 4-5) on MRI demonstrated cancer-1 case of Gleason 3 + 3 and 6 cases of Gleason >= 3 + 4 disease. Two cases with Likert 3 MR lesions revealed benign tissue upon biopsy. Two patients with no suspicious lesions on MRI were followed-up clinically, with PSA levels
remaining stable over a mean period of 17.5 months (range 7-28 months)."

According to the news reporters, the research concluded: "The use of prebiopsy multiparametric prostate MRI and subsequent cognitively targeted transperineal biopsy guided by visual registration can aid in the diagnostic pathway of patients with APR and a suspicion of prostate cancer."

For more information on this research see: Multiparametric Prostate Magnetic Resonance Imaging and Cognitively Targeted Transperineal Biopsy in Patients With Previous Abdominoperineal Resection and Susicion of Prostate Cancer. Urology, 2016;96():8-14. Urology can be contacted at: Elsevier Science Inc, 360 Park Ave South, New York, NY 10010-1710, USA. Researchers from Advanced Institute of Convergence Technology Describe Findings in Fabry Disease (alpha-Galactosidase delivery using 30Kc19-human serum albumin nanoparticles for effective treatment of Fabry disease)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Nutritional and Metabolic Diseases and Conditions - Fabry Disease have been presented. According to news originating from Suwon, South Korea, by NewsRx correspondents, research stated, "Fabry disease is a genetic lysosomal storage disease caused by deficiency of alpha-galactosidase, the enzyme-degrading neutral glycosphingolipid that is transported to lysosome. Glycosphingolipid accumulation by this disease causes multi-organ dysfunction and premature death of the patient."

Our news journalists obtained a quote from the research from the Advanced Institute of Convergence Technology, "Currently, enzyme replacement therapy (ERT) using recombinant alpha-galactosidase is the only treatment available for Fabry disease. To maximize the efficacy of treatment, enhancement of cellular delivery and enzyme stability is a challenge in ERT using alpha-galactosidase. In this study, protein nanoparticles using human serum albumin (HSA) and 30Kc19 protein, originating from silkworm, were used to enhance the delivery and intracellular alpha-galactosidase stability. 30Kc19-HSA nanoparticles loaded with the alpha-galactosidase were formed by desolvation method. 30Kc19-HSA nanoparticles had a uniform spherical shape and were well dispersed in cell culture media. 30Kc19-HSA nanoparticles had negligible toxicity to human cells. The nanoparticles exhibited enhanced cellular uptake and intracellular..."
stability of delivered alpha-galactosidase in human foreskin fibroblast. Additionally, they showed enhanced globotriaosylceramide degradation in Fabry patients’ fibroblasts."

According to the news editors, the research concluded: "It is expected that 30Kc19-HSA protein nanoparticles could be used as an effective tool for efficient delivery and enhanced stability of drugs."

For more information on this research see: alpha-Galactosidase delivery using 30Kc19-human serum albumin nanoparticles for effective treatment of Fabry disease. *Applied Microbiology and Biotechnology*, 2016;100(24):10395-10402. *Applied Microbiology and Biotechnology* can be contacted at: Springer, 233 Spring St, New York, NY 10013, USA. (Springer - www.springer.com; Applied Microbiology and Biotechnology - www.springerlink.com/content/0175-7598/)

The news correspondents report that additional information may be obtained from T.H. Park, Adv Inst Convergence Technol, Suwon, South Korea. Additional authors for this research include H.H. Park, Y. Sohn, J. Ryu, J.H. Park, W.J. Rhee and T.H. Park.

**Oncology - Thyroid Cancer**

**Researchers from Affiliated Hospital Detail Findings in Thyroid Cancer (Tall cell variant of papillary thyroid carcinoma: current evidence on clinicopathologic features and molecular biology)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Oncology - Thyroid Cancer. According to news reporting originating from Nanchong, People's Republic of China, by NewsRx correspondents, research stated, "Tall cell variant (TCV) of papillary thyroid carcinoma (PTC) has been recognized for the past few decades as an entity showing aggressive biological behavior; however, there is considerable controversy regarding the definition, clinical and pathological features of TCV because of its rarity and difficult diagnosis. No clinical features can accurately diagnose TCV."

Our news editors obtained a quote from the research from Affiliated Hospital, "Thus, the results of histocytology, immunohistochemistry and molecular genetics tests have important clinical implications for diagnosis. Given the aggressiveness and the increased recurrence and poor survival rates, more aggressive treatment approach and rigorous follow-up is required for patients with TCV."

According to the news editors, the research concluded: "In the present article, we undertook a comprehensive review to summarize and discuss the various aspects of this variant, from morphology to immunohistochemistry, and molecular abnormalities from a practical and
daily practice-oriented point of view."

For more information on this research see: Tall cell variant of papillary thyroid carcinoma: current evidence on clinicopathologic features and molecular biology. *Oncotarget*, 2016;7(26):40792-40799.

The news editors report that additional information may be obtained by contacting X. Wang, Dept. of General Surgery, Affiliated Hospital of North Sichuan Medical College, Nanchong, People's Republic of China. Additional authors for this research include W. Cheng, C. Liu and J. Li.

**Oncology - Gliomas**

**Researchers from Affiliated Hospital Detail New Studies and Findings in the Area of Gliomas (Low Expression of CAPON in Glioma Contributes to Cell Proliferation via the Akt Signaling Pathway)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Oncology - Gliomas. According to news reporting originating in Jiangsu, People's Republic of China, by NewsRx journalists, research stated, "CAPON is an adapter protein for nitric oxide synthase 1 (NOS1). CAPON has two isoforms in the human brain: CAPON-L (long form of CAPON) and CAPON-S (short form of CAPON)."

The news reporters obtained a quote from the research from Affiliated Hospital, "Recent studies have indicated the involvement of CAPON in tumorigenesis beyond its classical role in NOS1 activity regulation. In this study, we found that the protein levels of CAPON-S, but not than CAPON-L, were significantly decreased in glioma tissues. Therefore, we established lentivirus-mediated stable cell lines with CAPON-S overexpression or down-regulation, and investigated the role of CAPON-S in the proliferation of glioma cells by using CCK8, EdU, and flow cytometry assays. Overexpression of CAPON-S reduced the cell variability and the percentage of EdU-positive cells, and arrested the cells in the G1 phase in glioma cells. Silencing of CAPON by short-hairpin RNA showed the opposite effects. Furthermore, an intracellular signaling array revealed that overexpression of CAPON-S resulted in a remarkable reduction in the phosphorylation of Akt and S6 ribosomal protein in glioma cells, which was further confirmed by Western blot."

According to the news reporters, the research concluded: "These findings suggest that CAPON may function as a tumor suppressor in human brain glioma and that the inactivation of the Akt signaling pathway caused by CAPON-S overexpression may provide insight into the underlying mechanism of CAPON in glioma cell proliferation."

For more information on this research see: Low Expression of CAPON in Glioma Contributes to Cell Proliferation via the Akt Signaling Pathway. *International Journal of Molecular Sciences*, 2016;17(11):1475-1485. *International Journal of Molecular Sciences* can
Researchers from Affiliated Hospital of Nanjing University School of Medicine Report Findings in Ischemia (Endoplasmic reticulum stress of Kupffer cells involved in the conversion of natural regulatory T cells to Th17 cells in liver ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Ischemia have been published. According to news reporting originating in Nanjing, People's Republic of China, by NewsRx journalists, research stated, "Our previous studies have shown that regulatory T cells (Tregs) are reduced and Th17 cells are elevated in liver insults. Recent studies have indicated the critical role of endoplasmic reticulum (ER) stress of Kupffer cells (KCs) in evoking liver inflammation following reperfusion."

The news reporters obtained a quote from the research from the Affiliated Hospital of Nanjing University School of Medicine, "The objective of this study was to investigate the role of ER stress of KCs in the conversion of Tregs to Th17 cells and the effect on liver ischemia-reperfusion injury. The partial warm liver ischemia-reperfusion injury mouse model was adopted. ER stress of KCs and the frequency of Tregs and Th17 cells following reperfusion were analyzed. Apart from depletion and adoptive transfer of KCs, KCs were isolated from ischemic lobes and co-cultured with Tregs to study the effect of KCs on Tregs and Th17 cells. It was found that KCs induced ER stress, decreased natural Tregs (nTregs), and increased Th17 cells after reperfusion. Depletion of KCs modulated the reduction of nTregs and elevation of Th17 cells. Co-culture with stressed KCs led to the reduction in nTregs and elevation of Th17 cells. This effect was suppressed by anti-interleukin-6. Adoptive transfer of these stressed KCs resulted in the reduction in nTregs and elevation of Th17 cells and caused liver injury."

According to the news reporters, the research concluded: "Endoplasmic reticulum stress of KCs contributed to the conversion of nTregs to Th17 cells due to interleukin-6, resulting in the worsening of liver insult."

Our news correspondents report that additional information may be obtained by contacting J. Gao, Dept. of General Surgery, Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing University Medical School, Nanjing, People's Republic of China.
Additional authors for this research include Z. Jiang, S. Wang, Y. Zhou, X. Shi and M. Feng.

Hematology - Laboratory Hematology

Researchers from Aga Khan University Hospital Detail Findings in Laboratory Hematology (Analytical performance evaluation of a high-volume hematology laboratory utilizing sigma metrics as standard of excellence)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Hematology - Laboratory Hematology. According to news originating from Karachi, Pakistan, by NewsRx correspondents, research stated, "Around two-thirds of important clinical decisions about the management of patients are based on laboratory test results. Clinical laboratories are required to adopt quality control (QC) measures to ensure provision of accurate and precise results."

Our news journalists obtained a quote from the research from Aga Khan University Hospital, "Six sigma is a statistical tool, which provides opportunity to assess performance at the highest level of excellence. The purpose of this study was to assess performance of our hemotalogical parameters on sigma scale in order to identify gaps and hence areas of improvement in patient care. Twelve analytes included in the study were hemoglobin (Hb), hematocrit (Hct), red blood cell count (RBC), mean corpuscular volume (MCV), red cell distribution width (RDW), total leukocyte count (TLC) with percentages of neutrophils (Neutr%) and lymphocytes (Lymph %), platelet count (Plt), mean platelet volume (MPV), prothrombin time (PT), and fibrinogen (Fbg). Internal quality control data and external quality assurance survey results were utilized for the calculation of sigma metrics for each analyte. Acceptable sigma value of (>=)3 was obtained for the majority of the analytes included in the analysis. MCV, Plt, and Fbg achieved value of <3 for level 1 (low abnormal) control. PT performed poorly on both level 1 and 2 controls with sigma value of <3."

According to the news editors, the research concluded: "Despite acceptable conventional QC tools, application of sigma metrics can identify analytical deficits and hence prospects for the improvement in clinical laboratories."

The news correspondents report that additional information may be obtained from M.S. Shaikh, Section of Hematology, Dept. of Pathology and Laboratory Medicine, Aga Khan University Hospital, Karachi, Pakistan.

**Phenethylamines**

**Researchers from Ain Shams University Report Details of New Studies and Findings in the Area of Phenethylamines (Composite chitosan-transfersomal vesicles for improved transnasal permeation and bioavailability of verapamil)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Phenethylamines. According to news reporting originating in Cairo, Egypt, by NewsRx journalists, research stated, "The creation of composite systems has become an emerging field in drug delivery. Chitosan has demonstrated several pharmaceutical advantages, especially in intranasal delivery."

The news reporters obtained a quote from the research from Ain Shams University, "In this manuscript, a comparative study was conducted between regular vesicles (transfersomes and penetration enhancer vesicles) and composite vesicles (chitosan containing transfersomes and penetration enhancer vesicles) loaded with a model antihypertensive drug; verapamil hydrochloride VRP. Composite vesicles displayed larger particle size than regular vesicles owing to the coating potential of chitosan on the vesicular bilayer as displayed by transmission electron microscopy, with an increased viscosity of composite vesicles and a shift in the zeta potential values from negative to positive. The entrapment efficiency of VRP in the vesicles ranged from 24 to 64%, with best physical stability displayed with transfersomal vesicles prepared using sodium deoxycholate. Chitosan slowed the in vitro release of VRP from the selected formulation but managed to achieve high penetrability across sheep nasal mucosa as displayed by confocal laser microscopy. The chitosan composite transfersomal formulation exhibited absolute bioavailability of 81.83% compared to the oral solution which displayed only 13.04%.

According to the news reporters, the research concluded: "Findings of this manuscript highly recommend chitosan as a promising functional additive in vesicular formulations to improve the intranasal delivery of drugs with low oral bioavailability."

For more information on this research see: Composite chitosan-transfersomal vesicles for improved transnasal permeation and bioavailability of verapamil. *International Journal of Biological Macromolecules*, 2016;93():591-599. *International Journal of Biological Macromolecules* can be contacted at: Elsevier Science Bv, PO Box 211, 1000 Ae Amsterdam, Netherlands. Genetics - Human Genetics

Researchers from Aix-Marseille University Provide Details of New Studies and Findings in the Area of Human Genetics (Actionable Genes, Core Databases, and Locus-Specific Databases)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Genetics - Human Genetics. According to news reporting originating from Marseille, France, by NewsRx correspondents, research stated, "Adoption of next-generation sequencing (NGS) in a diagnostic context raises numerous questions with regard to identification and reports of secondary variants (SVs) in actionable genes. To better understand the whys and wherefores of these questioning, it is necessary to understand how they are selected during the filtering process and how their proportion can be estimated."

Our news editors obtained a quote from the research from Aix-Marseille University, "It is likely that SVs are underestimated and that our capacity to label all true SVs can be improved. In this context, Locus-specific databases (LSDBs) can be key by providing a wealth of information and enabling classifying variants. We illustrate this issue by analyzing 318 SVs in 23 actionable genes involved in cancer susceptibility syndromes identified through sequencing of 572 participants selected for a range of atherosclerosis phenotypes. Among these 318 SVs, only 43.4% are reported in Human Gene Mutation Database (HGMD) Professional versus 71.4% in LSDB. In addition, 23.9% of HGMD Professional variants are reported as pathogenic versus 4.8% for LSDB."

According to the news editors, the research concluded: "These data underline the benefits of LSDBs to annotate SVs and minimize overinterpretation of mutations thanks to their efficient curation process and collection of unpublished data."

The news editors report that additional information may be obtained by contacting G.
Researchers from Albert Einstein College of Medicine Describe Findings in Proinsulin (Genetic Variation near IRS1 is Associated with Adiposity and a Favorable Metabolic Profile in US Hispanics/Latinos)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Peptide Proteins - Proinsulin is now available. According to news originating from Bronx, New York, by NewsRx correspondents, research stated, "Associations of IRS1 genetic variation with adiposity and metabolic profile in U.S. Hispanic/Latino individuals of diverse backgrounds were examined."

Our news journalists obtained a quote from the research from the Albert Einstein College of Medicine, "Previously genome-wide association study-identified IRS1 variants (rs2943650, rs2972146, rs2943641, and rs2943634) as related to body fat percentage (BF%) and multiple metabolic traits were tested among up to 12,730 adults (5,232 men; 7,515 women) from the Hispanic Community Health Study/Study of Latinos. The C-allele (frequency=26%) of rs2943650 was significantly associated with higher BF% overall (beta = 0.34 +/- 0.11% per allele; P=0.002) and in women (beta = 0.41 +/- 0.14% per C-allele; P=0.003), but not in men (beta = 0.28 +/- 0.18% per C-allele; P=0.11), though there was no significant sex difference. Using the inverse normal-transformed data to compare effect sizes, it was found that the association with BF% was stronger in Hispanic/Latino women than that previously reported in European women (beta = 0.054 +/- 0.018SD vs. beta = 0.008 +/- 0.011SD per C-allele; P=0.03). The BF% -increasing allele of rs2943650 was significantly associated with lower levels of fasting insulin, homeostatic model assessment of insulin resistance, hemoglobin A1c, and triglycerides and higher high-density lipoprotein cholesterol (P <0.05). This study confirmed and extended previous findings of IRS1 variation associated with increased adiposity but a favorable metabolic profile in U.S."

According to the news editors, the research concluded: "Hispanics/Latinos, with a relatively stronger genetic effect on BF% in Hispanic/Latino women compared with European women."

For more information on this research see: Genetic Variation near IRS1 is Associated with Adiposity and a Favorable Metabolic Profile in US Hispanics/Latinos. Obesity, 2016:24(11):2407-2413. The news correspondents report that additional information may be obtained from Q.B. Qi, Albert Einstein College of Medicine, Dept. of Epidemiol & Populat Hlth, Bronx, NY 10467, United States. Additional authors for this research include S.M. Gogarten, L.S. Emery,
Researchers from All India Institute of Medical Sciences Report Findings in Glioblastomas (Therapy and progression--induced O6-methylguanine-DNA methyltransferase and mismatch repair alterations in recurrent glioblastoma multiforme)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Oncology - Glioblastomas are presented in a new report. According to news reporting originating in New Delhi, India, by NewsRx journalists, research stated, "Despite multimodality treatment protocol including surgical resection, radiotherapy, and chemotherapy in patients with glioblastoma multiforme (GBM), most suffer from treatment failure and tumor recurrence within a few months of initial surgery. The effectiveness of temozolomide (TMZ), the most commonly used chemotherapeutic agent, is largely dependent on the methylation status of the promoter of the gene O6-methylguanine-DNA methyltransferase (MGMT) and the integrity of the mismatch repair (MMR) system."

The news reporters obtained a quote from the research from the All India Institute of Medical Sciences, "Changes in these regulatory mechanisms at the time of recurrence may influence response to therapy. Deciphering the molecular mechanisms of resistance to these drugs may in future lead to improvised patient management. In this article, we provide an update of the spectrum of molecular changes that occur in recurrent GBMs, and thus may have an impact on patient survival and treatment response."

According to the news reporters, the research concluded: "For review, electronic search for the keywords 'Recurrent GBM', 'Recurrent GBM AND MGMT' 'Recurrent glioma AND MGMT', 'Recurrent GBM AND MMR' and 'Recurrent glioma AND MMR', 'Recurrent GBM AND MMR' and 'Recurrent glioma AND MMR' was done on PubMed and relevant citations were screened including cross-references."

For more information on this research see: Therapy and progression--induced O6-methylguanine-DNA methyltransferase and mismatch repair alterations in recurrent glioblastoma multiforme. Indian Journal of Cancer, 2015;52(4):568-73.

Cardiology

Researchers from Amirkabir University of Technology Describe Findings in Cardiology (Nanomaterials-based electrochemical immunosensors for cardiac troponin recognition: An illustrated review)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Cardiology. According to news originating from Tehran, Iran, by NewsRx correspondents, research stated, "Cardiac troponins (I and T) have been recommended as the biomarkers of choice for the serological diagnosis and prognosis of Acute Myocardial Infarction (AMI) because of their high sensitivity and specificity. Sensor designing has been developed by nanotechnology revolution presenting faster detection and better reproducibility."

Our news journalists obtained a quote from the research from the Amirkabir University of Technology, "This review highlights the nanotechnology impact on electrochemical immunosensor that have been developed for the determination of cardiac troponin and provides an overview of the various types of nano based diagnostic methods, along with significant advances over the last several years in related technologies. It is critically important to diagnose Cardio Vascular Disease (CVD) at early stages of its progression, which allows successful treatment and recovery of patients."

According to the news editors, the research concluded: "Therefore, it is essential to develop simple and sensitive CVD diagnostic methods that can detect cardiac troponin as biomarker based on different types of nanomaterials and their developmental and implicational aspects at very low concentrations in biological fluids."

The news correspondents report that additional information may be obtained from M. Rabiee, Amirkabir Univ Technol, Fac Biomed Engn, Biomat Grp, Tehran, Iran. Additional authors for this research include M. Rabiee, S.N. Alhosseini, M. Tahriri, S. Yazdanpanah, S.H. Alavi and L. Tayebi.

Researchers from Angers University Hospital Detail Findings in Coronary Vasospasm (Acute coronary vasospasm in a patient with eosinophilic granulomatosis with polyangiitis following NSAID administration A case report)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Heart Disorders and Diseases - Coronary Vasospasm are presented in a new report. According to news originating from Angers, France, by NewsRx correspondents, research stated, "Eosinophilic with polyangiitis (EGPA, formerly known as Churg-Strauss syndrome) is a rare systemic disease characterized by a small-vessel necrotizing vasculitis. Cardiac manifestations are broad-ranging and are associated with a poor prognosis."

Our news journalists obtained a quote from the research from Angers University Hospital, "Coronary vasospasm is uncommon. Here, we report a case of an acute coronary vasospasm in a patient with EGPA after corticosteroids withdrawal and nonsteroidal antiinflammatory drug (NSAID) introduction. This patient was initially misdiagnosed as bradykinin-mediated angioedema. A 30-year-old man presented with recurrence of abdominal pain and acute dyspnea. NSAID administration for pain during a flare was followed by coronary vasospasms leading to cardiac arrest. Corticosteroid treatment was recently interrupted by the patient. This case reports a rare cardiac complication of EGPA. NSAID might contribute to coronary vasospasm by eosinophilic degranulation in EGPA."

According to the news editors, the research concluded: "Moreover, corticosteroid compliance must be emphasized among patients who display EGPA with high cardiac risk to prevent fatal issues."

For more information on this research see: Acute coronary vasospasm in a patient with eosinophilic granulomatosis with polyangiitis following NSAID administration A case report. Medicine, 2016;95(47):72-74. Medicine can be contacted at: Lippincott Williams & Wilkins, Two Commerce Sq, 2001 Market St, Philadelphia, PA 19103, USA. (Elsevier - www.elsevier.com; Medicine - www.journals.elsevier.com/medicine/)

Clinical Research - Clinical Trials and Studies

Researchers from Aristotle University Report on Findings in Clinical Trials and Studies (Echocardiographic Parameters During Long and Short Interdialytic Intervals in Hemodialysis Patients)
The researchers investigated the interdialytic changes in right and left ventricular function during the 2-and 3-day intervals. Observational study with 2 random crossover sequences of recordings: 3-day followed by 2-day interval or vice versa. 41 stable patients with end-stage renal disease on standard thrice-weekly hemodialysis therapy. Predictor: 3-day (long) versus 2-day (short) interdialytic interval. Interdialytic change in echocardiographic indexes of left and right ventricular function. 2-dimensional echocardiographic and tissue Doppler imaging studies were performed with a Vivid 7 cardiac ultrasound system at the start and end of the 3- and 2-day interdialytic intervals. During both intervals studied, elevations in cardiac output, stroke volume, left ventricular mass index, and peak early diastolic velocities of the left ventricle were evident. Interdialytic weight gain (3.0 +/- 1.7 vs 2.4 +/- 1.3 [SD] kg) and inferior vena cava diameter increase (0.54 +/- 0.3 vs 0.25 +/- 0.3) were higher during the 3-day versus the 2-day interval (P < 0.001). Left ventricular systolic and diastolic function indexes were generally no different between interdialytic intervals. In contrast, interdialytic increases in left and right atrial volume, right ventricular systolic pressure (RVSP; 15.3 +/- 10.2 vs 4.7 +/- 5.2 mm Hg; P< 0.001), and tricuspid regurgitation maximum velocity (0.46 +/- 0.45 vs 0.14 +/- 0.33 m/s; P = 0.001) were significantly greater during the 3- versus the 2-day interval. Multivariable analysis suggested that changes in interdialytic weight gain, right ventricle diastolic function, and pulmonary vascular resistance were determinants of the change in RVSP. Limitations: Observational study design.

According to the news reporters, the research concluded: "Excess volume accumulation over the long interdialytic interval in hemodialysis patients results in higher left and right atrial enlargement and RVSP elevation, which clinically corresponds to pulmonary circulation overload, providing one plausible pathway for the excess mortality risk during this period."

Our news journalists report that additional information may be obtained by contacting K. Tsilonis, Aristotle University, AHEPA Hosp, Dept. of Med 1, Sect Nephrol & Hypertens, Thessaloniki, Greece. Researchers from Arizona State University Detail Findings in Community Psychology (Rural-urban Disparities In Adolescent Risky Behaviors: A Family Social Capital Perspective)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Psychology - Community Psychology are presented in a new report. According to news originating from Tempe, Arizona, by NewsRx correspondents, research stated, "This study examined differences in adolescent risky behaviors between rural communities and urban communities and identified specific factors predicting these differences from a family social capital perspective. Secondary data analysis was conducted using the 2012 state-wide representative youth survey (N = 61,321) in Arizona, United States."

Our news journalists obtained a quote from the research from Arizona State University, "The results mostly confirmed the already documented differences between rural-urban youth and related health disparities. The rates of cigarette use, alcohol use and driving after drinking were higher in rural respondents than those in urban respondents. However, the rate of drug use such as marijuana and methamphetamines was lower in rural respondents. The findings highlighted the importance of family structure, family relationships, and socio-economic status as contributor to these rural/urban differences."

According to the news editors, the research concluded: "These results were discussed from family capital perspective and practice and policy recommendations were provided for the United States and other societies like China that face similar rural-urban disparities in youth behavioral health."

Keywords for this news article include: Tempe, Arizona, United States, North and Central America, Community Psychology, Psychology, Arizona State University.

Researchers from Asia University Provide Details of New Studies and Findings in the Area of Cell Biology (Deubiquitination and Stabilization of PD-L1 by CSN5)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Life Science Research - Cell Biology. According to news originating from Taichung, Taiwan, by NewsRx correspondents, research stated, "Pro-inflammatory cytokines produced in the tumor microenvironment lead to eradication of anti-tumor immunity and enhanced tumor cell survival. In the current study, we identified tumor necrosis factor alpha (INF-alpha) as a major factor triggering cancer cell immunosuppression against T cell surveillance via stabilization of programmed cell death-ligand 1 (PD-L1)."

Funders for this research include NIH, Cancer Prevention Research Institute of Texas, Patel Memorial Breast Cancer Endowment Fund, National Breast Cancer Foundation, Breast Cancer Research Foundation, University of Texas MD Anderson Cancer Center, China Medical University, Hospital Sister Institution Fund, Ministry of Science and Technology, International Research-intensive Centers of Excellence, Ministry of Health and Welfare, Center for Biological Pathways, Cure Postdoctoral Fellowship, National Research Foundation of Korea.

Our news journalists obtained a quote from the research from Asia University, "We demonstrated that COP9 signalosome 5 (CSN5), induced by NF-kappa B p65, is required for TNF-alpha-mediated PD-L1 stabilization in cancer cells. CSN5 inhibits the ubiquitination and degradation of PD-L1."

According to the news editors, the research concluded: "Inhibition of CSN5 by curcumin diminished cancer cell PD-L1 expression and sensitized cancer cells to anti-CTLA4 therapy."

For more information on this research see: Deubiquitination and Stabilization of PD-L1 by CSN5. Cancer Cell, 2016;30(6):925-939. Cancer Cell can be contacted at: Cell Press, 600 Technology Square, 5TH Floor, Cambridge, MA 02139, USA. (Elsevier - www.elsevier.com; Cancer Cell - www.journals.elsevier.com/cancer-cell/)

Researchers from AstraZeneca Report on Findings in Ethers (Discovery of indazole ethers as novel, potent, non-steroidal glucocorticoid receptor modulators)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on ethers have been published. According to news reporting from Molndal, Sweden, by NewsRx journalists, research stated, "A structure-based design approach led to the identification of a novel class of indazole ether based, nonsteroidal glucocorticoid receptor (GR) modulators. Several examples were identified that displayed cell potency in the picomolar range, inhibiting LPS-induced TNF-alpha release by primary peripheral blood mononuclear cells (PBMCs)."

The news correspondents obtained a quote from the research from AstraZeneca, "Additionally, an improved steroid hormone receptor binding selectivity profile, compared to classical steroidal GR agonists, was demonstrated. The indazole ether core tolerated a broad range of substituents allowing for modulation of the physiochemical parameters."

According to the news reporters, the research concluded: "A small subset of indazole ethers, with pharmacokinetic properties suitable for oral administration, was investigated in a rat antigen-induced joint inflammation model and demonstrated excellent anti-inflammatory efficacy."

Our news journalists report that additional information may be obtained by contacting M. Hemmerling, AstraZeneca, Resp Inflamm & Autoimmun Innovat Med & Early De, S-43183 Molndal, Sweden. Additional authors for this research include K. Edman, M. Lepisto, A. Eriksson, S. Ivanova, J. Dahmen, H. Rehwinkel, M. Berger, R. Hendrickx, M. Dearman, T.J. Jensen, L. Wissler and T. Hansson.

Researchers from Australian Army Malaria Institute Detail New Studies and Findings in the Area of Malaria (The Spiroindolone KAE609 Does Not Induce Dormant Ring Stages in Plasmodium falciparum Parasites)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Mosquito-Borne Diseases - Malaria have been published. According to news reporting originating from Brisbane, Australia, by NewsRx correspondents, research stated, "In vitro drug treatment with artemisinin derivatives, such as dihydroartemisinin (DHA), results in a temporary growth arrest (i.e., dormancy) at an early ring stage in Plasmodium falciparum. This response has been proposed to play a role in the recrudescence of P. falciparum infections following monotherapy with artesunate and may contribute to the development of artemisinin resistance in P. falciparum malaria."

Our news editors obtained a quote from the research from Australian Army Malaria Institute, "We demonstrate here that artemether does induce dormant rings, a finding which further supports the class effect of artemisinin derivatives in inducing the temporary growth arrest of P. falciparum parasites. In contrast and similarly to lumefantrine, the novel and fast-acting spiroindolone compound KAE609 does not induce growth arrest at the early ring stage of P. falciparum and prevents the recrudescence of DHA-arrested rings at a low concentration (50 nM)."

According to the news editors, the research concluded: "Our findings, together with previous clinical data showing that KAE609 is active against artemisinin-resistant K13 mutant parasites, suggest that KAE609 could be an effective partner drug with a broad range of antimalarials, including artemisinin derivatives, in the treatment of multidrug-resistant P. falciparum malaria."

For more information on this research see: The Spiroindolone KAE609 Does Not Induce Dormant Ring Stages in Plasmodium falciparum Parasites. *Antimicrobial Agents and Chemotherapy*, 2016;60(9):5167-5174. *Antimicrobial Agents and Chemotherapy* can be contacted at: Amer Soc Microbiology, 1752 N St NW, Washington, DC 20036-2904, USA. Researchers from Autonomous University Describe Findings in Aedes aegypti [Knockdown Resistance Mutations in Aedes aegypti (Diptera: Culicidae) From Puerto Rico]

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Mosquito Species - Aedes aegypti. According to news originating from Nuevo Leon, Mexico, by NewsRx correspondents, research stated, "Permethrin resistance is widespread in Aedes aegypti (L.), the main dengue, zika, and chikungunya virus vector in Latin America and the Caribbean. A common mechanism of resistance to pyrethroids-knockdown resistance (kdr)-is conferred through mutations in the insect's voltage-dependent sodium channel."

Our news journalists obtained a quote from the research from Autonomous University, "In this mosquito, around 10 replacement substitutions in the voltage-gated sodium channel gene (vgsc) have been reported in pyrethroid-resistant strains. Two of these mutations, named Ile1,016 and Cys1,534, are widespread in mosquito populations from Latin America and the Caribbean. This study assessed the levels of permethrin resistance and the frequency of two kdr mutations in eight Ae. aegypti populations collected in Puerto Rico in 2013. Permethrin resistance factors ranged from 33-214-fold relative to the New Orleans reference strain. The frequency of kdr mutation Ile1,016 ranged from 0.65 to fixation (1.0), and for Cys1,534 frequencies varied from 0.8 to fixation. Alarmingly, two populations-Carolina and Caguas-reached fixation at both loci."

According to the news editors, the research concluded: "Our results suggest that permethrin effectiveness for Ae. aegypti control is compromised in these collections from Puerto Rico."

Researchers from Autonomous University Describe Findings in Alzheimer Disease (Simultaneous monitoring of monoamines, amino acids, nucleotides and neuropeptides by liquid chromatography-tandem mass spectrometry and its application to ...

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Neurodegenerative Diseases and Conditions - Alzheimer Disease. According to news originating from Madrid, Spain, by NewsRx correspondents, research stated, "The primary functions of adrenal medullary chromaffin cells are the synthesis and storage in their chromaffin vesicles of the catecholamines noradrenaline (NA) and adrenaline (AD), and their subsequent release into the bloodstream by Ca2+-dependent exocytosis under conditions of fear or stress (fight or flight response). Several monoamines, nucleotides and opiates, such as leucine-enkephalin (LENK) and methionine-enkephalin (MENK), are also co-stored and co-released with the catecholamines."

Our news journalists obtained a quote from the research from Autonomous University, "However, other neurotransmitters have not been studied in depth. Here, we present a novel high-resolution liquid chromatography-tandem mass spectrometry approach for the simultaneous monitoring of 14 compounds stored and released in bovine chromaffin cells (BCCs). We validated the analytical method according to the recommendations of the EMA and FDA by testing matrix effect, selectivity, sensitivity, precision, accuracy, stability and carry-over. After testing on six batches of BCCs from different cultures, the method enabled simultaneous quantitative determination of monoamines (AD, NA, dopamine, serotonin, 5-hydroxyindoleacetic acid, histamine and metanephrine), amino acids (L-glutamic acid, gamma-aminobutyric acid), nucleotides (adenosine 5'-diphosphate, adenosine 5'-monophosphate, cyclic adenosine 5'-monophosphate) and neuropeptides (LENK and MENK) in the intracellular content, basal secretion and acetylcholine induced secretion of BCCs. The high-resolution approach used here enabled us to determine the levels of 14 compounds in the same BCC batch in only 16min. This novel approach will make it possible to study the regulatory mechanisms of Ca2+ signaling, exocytosis and endocytosis using different neurotrophic factors and/or secretagogues as stimuli in primary BCC cultures."

According to the news editors, the research concluded: "Our method is actually being applied to human plasma samples of different therapeutic areas where sympathoadrenal axis is involved in stress situations such as Alzheimer's disease, migraine or cirrhosis, to improve diagnosis and clinical practice."

Angiology
Researchers from Baylor University College of Medicine Discuss Findings in Angiology (Alterations in gait parameters with peripheral artery disease: The importance of pre-frailty as a confounding variable)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Angiology. According to news reporting out of Houston, Texas, by NewsRx editors, research stated, "Although poor walking is the most common symptom of peripheral artery disease (PAD), reported results are inconsistent when comparing gait parameters between PAD patients and healthy controls. This inconsistency may be due to frailty, which is highly prevalent among PAD patients."

Our news journalists obtained a quote from the research from the Baylor University College of Medicine, "To address this hypothesis, 41 participants, 17 PAD (74 +/- 8 years) and 24 aged-matched controls (76 +/- 7 years), were recruited. Gait was objectively assessed using validated wearable sensors. Analysis of covariate (ANCOVA) tests were used to compare gait parameters between PAD and non-PAD groups, considering age, gender, and body mass index as covariates, while stratified based on frailty status. According to the Fried frailty index, 47% of PAD and 50% of control participants were non-frail and the rest were classified as pre-frail. Within non-frail participants, gait speed, body sway during walking, stride length, gait cycle time, double-support, knee range of motion, speed variability, mid-swing speed, and gait initiation were significantly different between PAD and control groups (effect size d = 0.75 +/- 0.43). In the pre-frail group, however, most of the gait differences were diminished except for gait initiation and gait variability. Results suggest that gait initiation is the most sensitive parameter for detecting gait impairment in PAD participants when compared to controls, regardless of frailty status (d = 1.30-1.41; p<0.050)."

According to the news editors, the research concluded: "The observed interaction effect between frailty and PAD on gait parameters confirms the importance of assessing functionality in addition to age to provide more consistency in detecting motor performance impairments due to PAD."

Researchers from Beaujon Hospital Detail New Studies and Findings in the Area of Escherichia coli (Prospective Cohort Study of the Relative Abundance of Extended-Spectrum-Beta-Lactamase-Producing Escherichia coli in the Gut of Patients Admitted ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Gram-Negative Bacteria - Escherichia coli have been published. According to news reporting originating in Clichy, France, by NewsRx journalists, research stated, "A total of 458 patients were prospectively included at hospital admission and screened for extended-spectrum-beta-lactamase-producing (ESBL) Escherichia coli carriage in 2007 and in 2010 to 2012."

The news reporters obtained a quote from the research from Beaujon Hospital, "A 4-fold increase in ESBL carriage (3% to 12%), a 5-fold increase in numbers of community patients among ESBL carriers, and a higher number of multiple ESBL strains was found in the 2010 to 2012 period. ESBL E. coli represented the dominant E. coli strain (relative abundance, >50%) in 10/32 (31%) of ESBL carriers."

According to the news reporters, the research concluded: "This represents a major threat in terms of infectious risk and dissemination."

For more information on this research see: Prospective Cohort Study of the Relative Abundance of Extended-Spectrum-Beta-Lactamase-Producing Escherichia coli in the Gut of Patients Admitted to Hospitals. Antimicrobial Agents and Chemotherapy, 2016;60(11):6941-6944. Antimicrobial Agents and Chemotherapy can be contacted at: Amer Soc Microbiology, 1752 N St NW, Washington, DC 20036-2904, USA. Researchers from Beckman Research Institute Detail Findings in Prostate Cancer (High-Throughput Screen for Inhibitors of Androgen Receptor-RUNX2 Transcriptional Regulation in Prostate Cancer)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Oncology - Prostate Cancer have been presented. According to news originating from Duarte, California, by NewsRx correspondents, research stated, "Runt-related transcription factor 2 (RUNX2) plays a critical role in prostate cancer progression. RUNX2 interacts with the androgen receptor (AR) and modulates its transcriptional activity in a locus-specific manner."

Our news journalists obtained a quote from the research from Beckman Research Institute, "RUNX2 and AR synergistically stimulate a subset of genes, including the pro-oncogene snail family zinc finger 2 (SNAI2). AR-RUNX2 signaling cooperatively induces invasiveness of prostate cancer cells via SNAI2; and coexpression of AR, RUNX2, and SNAI2 in prostate cancer biopsy samples predicts disease recurrence. Competitive inhibition of AR alone could not disrupt the synergistic activation of SNAI2. We therefore established a phenotypic cell-based screening assay for compounds that could inhibit AR-RUNX2 synergistic activity either directly or indirectly. This assay was used to screen 880 compounds as a proof of concept, resulting in identification of several compounds that disrupted the synergistic stimulation of genes. Further investigation suggested the involvement of epidermal growth factor receptor (EGFR) signaling in AR/RUNX2 synergistic activity."

According to the news editors, the research concluded: "Our assay is amenable to high-throughput screening and can be used to identify inhibitors of the AR-RUNX2 interaction in prostate cancer cells."

For more information on this research see: High-Throughput Screen for Inhibitors of Androgen Receptor-RUNX2 Transcriptional Regulation in Prostate Cancer. *Journal of Pharmacology and Experimental Therapeutics*, 2016;359(2):256-261. *Journal of Pharmacology and Experimental Therapeutics* can be contacted at: Amer Soc Pharmacology Experimental Therapeutics, 9650 Rockville Pike, Bethesda, MD 20814-3995, USA.

Researchers from Beijing Normal University Detail New Studies and Findings in the Area of Neuroimaging (Effects of craving behavioral intervention on neural substrates of cue-induced craving in Internet gaming disorder)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Medical Imaging - Neuroimaging have been presented. According to news originating from Beijing, People's Republic of China, by NewsRx correspondents, research stated, "Internet gaming disorder (IGD) is characterized by high levels of craving for online gaming and related cues. Since addiction-related cues can evoke increased activation in brain areas involved in motivational and reward processing and may engender gaming behaviors or trigger relapse, ameliorating cue-induced craving may be a promising target for interventions for IGD."

Our news journalists obtained a quote from the research from Beijing Normal University, "This study compared neural activation between 40 IGD and 19 healthy control (HC) subjects during an Internet-gaming cue-reactivity task and found that IGD subjects showed stronger activation in multiple brain areas, including the dorsal striatum, brainstem, substantia nigra, and anterior cingulate cortex, but lower activation in the posterior insula. Furthermore, twenty-three IGD subjects (CBI+ group) participated in a craving behavioral intervention (CBI) group therapy, whereas the remaining 17 IGD subjects (CBI-group) did not receive any intervention, and all IGD subjects were scanned during similar time intervals. The CBI+ group showed decreased IGD severity and cue-induced craving, enhanced activation in the anterior insula and decreased insular connectivity with the lingual gyrus and precuneus after receiving CBI."

According to the news editors, the research concluded: "These findings suggest that CBI is effective in reducing craving and severity in IGD, and it may exert its effects by altering insula activation and its connectivity with regions involved in visual processing and attention bias."

The news correspondents report that additional information may be obtained from X.Y. Fang, Beijing Normal University, Inst Dev Psychol, Beijing 100875, People's Republic of China. Researchers from Ben-Gurion University of the Negev Detail New Studies and Findings in the Area of Cardiovascular Diseases (Novel Compounds Targeting the Mitochondrial Protein VDAC1 Inhibit Apoptosis and Protect against Mitochondrial Dysfunction)

According to news reporting out of Beer Sheva, Israel, by NewsRx editors, research stated, "Apoptosis is thought to play a critical role in several pathological processes, such as neurodegenerative diseases (i.e. Parkinson's and Alzheimer's diseases) and various cardiovascular diseases."

Our news journalists obtained a quote from the research from the Ben-Gurion University of the Negev, "Despite the fact that apoptotic mechanisms are well defined, there is still no substantial therapeutic strategy to stop or even slow this process. Thus, there is an unmet need for therapeutic agents that are able to block or slow apoptosis in neurodegenerative and cardiovascular diseases. The outer mitochondrial membrane protein voltage-dependent anion channel 1 (VDAC1) is a convergence point for a variety of cell survival and death signals, including apoptosis. Recently, we demonstrated that VDAC1 oligomerization is involved in mitochondrion-mediated apoptosis. Thus, VDAC1 oligomerization represents a prime target for agents designed to modulate apoptosis. Here, high-throughput compound screening and medicinal chemistry were employed to develop compounds that directly interact with VDAC1 and prevent VDAC1 oligomerization, concomitant with an inhibition of apoptosis as induced by various means and in various cell lines. The compounds protected against apoptosis-associated mitochondrial dysfunction, restoring dissipated mitochondrial membrane potential, and thus cell energy and metabolism, decreasing reactive oxidative species production, and preventing detachment of hexokinase bound to mitochondria and disruption of intracellular Ca2+ levels. Thus, this study describes novel drug candidates with a defined mechanism of action that involves inhibition of VDAC1 oligomerization, apoptosis, and mitochondrial dysfunction."

According to the news editors, the research concluded: "The compounds VBIT-3 and VBIT-4 offer a therapeutic strategy for treating different diseases associated with enhanced apoptosis and point to VDAC1 as a promising target for therapeutic intervention."

Our news journalists report that additional information may be obtained by contacting V. Shoshan-Barmatz, Ben Gurion University of the Negev, Natl Inst Biotechnol Negev, IL-84105 Beer Sheva, Israel. Additional authors for this research include R. Begas-Shvartz, M. Shalev, A. Shteinfer-Kuzmine, A. Gruzman, S. Reina, V. De Pinto and V. Shoshan-Barmatz.

Researchers from Bhabha Atomic Research Center Report Recent Findings in Cardiology (Ga-68 labeled fatty acids for cardiac metabolic imaging: Influence of different bifunctional chelators)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Cardiology is now available. According to news reporting originating from Maharashtra, India, by NewsRx correspondents, research stated, "Development of Ga-68 labeled fatty acids is of immense interest due to the availability of Ga-68 through a generator and its superiority over SPECT based tracers in carrying out dynamic imaging on a PET scanner. Our present work explores the influence of different chelators on the cardiac uptake and pharmacokinetics of the Ga-68-labeled fatty acids."

Our news editors obtained a quote from the research from Bhabha Atomic Research Center, "Two new Ga-68 labeled fatty acids were synthesized by conjugation of 11-aminoundecanoic acid with the bifunctional chelators (BFCs) viz. p-SCN-Bn-DTPA (S-2-(4-isothiocyanatobenzyl)- diethylenetriaminepentaacetic acid) and p-SCN-Bn-NODAGA (S-2-(4-isothiocyanatobenzyl)-1,4,7-triazacyclononane-1-glu taric acid-4,7-acetic acid) and their comparison was carried out with the previously reported Ga-68-NOTA-undecanoic acid. Both the conjugates were radiolabeled with Ga-68 in high yields and purities (> 95%). Their formation was established by preparation and characterization of their inactive analogs with natGa at macroscopic levels. Biodistribution studies of the complexes in Swiss mice showed lower initial myocardial uptake for Ga-68-NODAGA-undecanoic acid (3.8 +/- 0.6% ID/g) and Ga-68-DTPA-undecanoic acid (1.3 +/- 0.5% ID/g) complexes in comparison to previously reported Ga-68-NOTA-undecanoic acid complex (7.4 +/- 0.6% ID/g) complexes in comparison to previously reported Ga-68-NOTA-undecanoic acid complex (7.4 +/- 2.8% ID/g) at 2 min p.i. However, significant retention of the tracer in the myocardium was observed in the case of Ga-68-NODAGA-undecanoic complex, which led to improved heart/non-target ratios of the complex over time in comparison to the other Ga-68 complexes. Similarly, the DTPA complex exhibited increased washout from the liver in comparison to other Ga-68 derivatives. The beta oxidation mechanism in myocytes was investigated by isolating the myocardial extract post intravenous injection of the respective Ga-68 complexes and analyzing them by radio-HPLC, which showed metabolic transformation of the parent fatty acid complex peak in all the three complexes."

According to the news editors, the research concluded: "This study has provided an insight into the design characteristics of Ga-68 labeled fatty acids to achieve the desired myocardial imaging characteristics."

The news editors report that additional information may be obtained by contacting A.
Researchers from Biomedical Center Report New Studies and Findings in the Area of Oxalates (Massive excretion of calcium oxalate from late prepupal salivary glands of Drosophila melanogaster demonstrates active nephridial-like anion transport)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Oxalates have been published. According to news reporting from Bratislava, Slovakia, by NewsRx journalists, research stated, "The Drosophila salivary glands (SGs) were well known for the puffing patterns of their polytene chromosomes and so became a tissue of choice to study sequential gene activation by the steroid hormone ecdysone. One well-documented function of these glands is to produce a secretory glue, which is released during pupariation to fix the freshly formed puparia to the substrate."

Funders for this research include Grantova Agentura Ceske Republiky, UNCE, OPPK Grant, BIOCEV, Prvouk/LF1/1, Vedecka Grantova Agentura MŠVVaŠ SR a SAV, EEA-Norwegian FM. The news correspondents obtained a quote from the research from Biomedical Center, "Over the past two decades SGs have been used to address specific aspects of developmentally-regulated programmed cell death (PCD) as it was thought that they are doomed for histolysis and after pupariation are just awaiting their fate. More recently, however, we have shown that for the first 3-4 h after pupariation SGs undergo tremendous endocytosis and vacuolation followed by vacuole neutralization and membrane consolidation. Furthermore, from 8 to 10 h after puparium formation (APF) SGs display massive apocrine secretion of a diverse set of cellular proteins. Here, we show that during the period from 11 to 12 h APF, the prepupal glands are very active in calcium oxalate (CaOx) extrusion that resembles renal or nephridial excretory activity. We provide genetic evidence that Prestin, a Drosophila homologue of the mammalian electrogenic anion exchange carrier SLC26A5, is responsible for the instantaneous production of CaOx by the late prepupal SGs. Its positive regulation by the protein kinases encoded by fray and wnk lead to increased production of CaOx. The formation of CaOx appears to be dependent on the cooperation between Prestin and the vATPase complex as treatment with bafilomycin A(1) or concanamycin A abolishes the production of detectable CaOx."

According to the news reporters, the research concluded: "These data demonstrate that prepupal SGs remain fully viable, physiologically active and engaged in various cellular activities at least until early pupal period, that is, until moments prior to the execution of PCD."

Researchers from Biotechnology Institute Report New Studies and Findings in the Area of Chemotherapy (Characterization of Two Multidrug-Resistant IncA/C Plasmids from the 1960s by Using the MinION Sequencer Device)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Drugs and Therapies - Chemotherapy. According to news originating from Godollo, Hungary, by NewsRx correspondents, research stated, "Two A/C incompatibility group (IncA/C family) plasmids from the 1960s have been sequenced and classified into the A/C2 type 1 group. R16a and IP40a contain novel antibiotic resistance islands and a complete GIsul2 genomic island not previously found in the family."

Financial support for this research came from Orszagos Tudomanyos Kutatasi Alapprogramok (OTKA).

Our news journalists obtained a quote from the research from Biotechnology Institute, "In the 173.1-kb R16a, the 29.9-kb antibiotic resistance island (ARI) is located in a unique backbone position not utilized by ARIs. ARI(R16a) consists of Tn1, Tn6020, and Tn6333, harboring the resistance genes bla(TEM-1D) and aphA1b and a mer module, respectively; a truncated Tn5393 copy; and a gene cluster with unknown function. Plasmid IP40a is 170.4 kb in size and contains a 5.6-kb ARI inserted into the kfrA gene. ARI(IP40a) carrying blaTEM-1D and aphA1b genes is composed of Tn1 with a Tn6023 insertion. Additionally, IP40a harbors single IS2, IS186, and Tn1000 insertions scattered in the backbone; an IS150 copy in GIsul2; and a complete Tn6333 carrying a mer module at the position of ARI (R16a). Loss of resistance markers in R16a, IP40a, and R55 was observed during stability tests. Every phenotypic change proved to be the result of recombination events involving mobile elements. Intramolecular transposition of IS copies that generated IP40a derivatives lacking large parts of the backbone could account for the formation of other family members, too. The MinION platform proved to be a valuable tool in bacterial genome sequencing since it generates long reads that span repetitive elements and facilitates full-length plasmid or chromosome assembly."

According to the news editors, the research concluded: "Nanopore technology enables rapid characterization of large, low-copy-number plasmids and their rearrangement products."
Researchers from Brigham and Women's Hospital Describe Findings in Heart Attack (Effect of stimulus type and temperature on EEG reactivity in cardiac arrest)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Heart Disorders and Diseases - Heart Attack have been published. According to news reporting from Boston, Massachusetts, by NewsRx journalists, research stated, "Electroencephalogram (EEG) background reactivity is a reliable outcome predictor in cardiac arrest patients post therapeutic hypothermia. However, there is no consensus on modality testing and prior studies reveal only fair to moderate agreement rates."

Funders for this research include NINDS, UCB, Duke Clinical Research Institute, Sunovion, Inc, American Academy of Neurology, The American Brain Foundation, Bristol-Myers Squibb, Daiichi-Sankyo, GlaxoSmithKline, Johnson and Johnson, Bayer HealthCare, Gilead, Eisai, Merck, Lexicon, St. Jude’s Medical, Boston Clinical Research Institute, University of Calgary, Forest Pharmaceuticals.

The news correspondents obtained a quote from the research from Brigham and Women's Hospital, "The aim of this study was to explore different stimulus modalities and report interrater agreements. We studied a multicenter, prospectively collected cohort of cardiac arrest patients who underwent therapeutic hypothermia between September 2014 and December 2015. We identified patients with reactivity data and evaluated interrater agreements of different stimulus modalities tested in hypothermia and normothermia. Of the 60 patients studied, agreement rates were moderate to substantial during hypothermia and fair to moderate during normothermia. Bilateral nipple pressure is more sensitive (80%) when compared to other modalities in eliciting a reactive background in hypothermia. Auditory, nasal tickle, nailbed pressure and nipple pressure reactivity were associated with good outcomes in both hypothermia and normothermia. EEG reactivity varies depending on the stimulus testing modality as well as the temperature during which stimulation is performed, with nipple pressure emerging as the most sensitive during hypothermia for reactivity and outcome determination."
According to the news reporters, the research concluded: "This highlights the importance of multiple stimulus testing modalities in EEG reactivity determination to reduce false negatives and optimize prognostication."

Our news journalists report that additional information may be obtained by contacting T.A. Fantaneanu, Brigham & Women's Hospital, Dept. of Neurol, Boston, MA 02115, United States. Additional authors for this research include B. Tolchin, V. Alvarez, R. Friolet, K. Avery, B.M. Scirica, M. O'Brien, G.V. Henderson and J.W. Lee.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1016/j.clinph.2016.09.002. This DOI is a link to an online electronic document that is either free or for purchase.

**Heart Disorders and Diseases - Hypertrophic…**

**Researchers from Brigham and Women’s Hospital Detail New Studies and Findings in the Area of Hypertrophic Cardiomyopathy (Evolution of hypertrophic cardiomyopathy in sarcomere mutation carriers)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Heart Disorders and Diseases - Hypertrophic Cardiomyopathy have been published. According to news reporting from Boston, Massachusetts, by NewsRx journalists, research stated, "The early natural history of sarcomere mutations and the evolution to hypertrophic cardiomyopathy (HCM) are poorly characterised. To describe phenotypic progression, we compared mutation carriers who developed HCM to those who did not during prospective longitudinal investigation."

Financial support for this research came from National Heart, Lung, and Blood Institute.

The news correspondents obtained a quote from the research from Brigham and Women's Hospital, "Sarcomere mutation carriers without baseline left ventricular hypertrophy (LVH) were studied during participation in a pilot clinical trial testing diltiazem versus placebo. 38 participants (mean +/- SD age 15.8 +/- 8.6 years) were followed for a median of 2.9 years (range 1.0-5.1 years) with imaging and biomarker analysis. 4 participants (mean baseline age 13.8 +/- 3.9 years) developed HCM and were compared to those without phenotypic progression. Participants who developed HCM were all children/adolescents and members of families with more highly penetrant mutations. At baseline, participants who developed HCM had a higher left ventricular (LV) ejection fraction (74 +/- 2% vs 69 +/- 1%, p= 0.02), lower global E0 velocity (11.2 +/- 0.5 vs 14.8 +/- 0.4 cm/s, p<0.0001), higher N terminal pro peptide of B-type natriuretic peptide (NT-proBNP) values (208 +/- 72 vs 57 +/- 13 pg/mL, p=0.04),
longer posterior mitral leaflets, and more prevalent ECG abnormalities. During followup, these parameters and cardiac troponin values continued to diverge in participants who developed HCM, although LV wall thickness stabilised. LV relaxation, ECG changes, mitral leaflet length, and serum NT-proBNP concentrations appeared more prominently abnormal at baseline in preclinical sarcomere mutation carriers who imminently progressed to HCM. LVH appears to stabilise within 2 years of onset."

According to the news reporters, the research concluded: "Further investigation is needed to improve our understanding of the evolution of this disease."

For more information on this research see: Evolution of hypertrophic cardiomyopathy in sarcomere mutation carriers. Heart, 2016;102(22):1805-1812. Heart can be contacted at: Bmj Publishing Group, British Med Assoc House, Tavistock Square, London WC1H 9JR, England. (BMJ Publishing Group - group.bmj.com/; Heart - heart.bmj.com/)

Drug Development

Researchers from Bristol-Myers Squibb Discuss Findings in Drug Development (Improving Drug Design: An Update on Recent Applications of Efficiency Metrics, Strategies forReplacing Problematic Elements, and Compounds in Nontraditional Drug Space)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Drug Development have been published. According to news reporting out of Wallingford, Connecticut, by NewsRx editors, the research stated, "Drug discovery and development is a complex and lengthy enterprise that suffers from high rates of candidate attrition at all stages of the process. The physical, biological, and toxicological properties of a drug candidate are inextricably linked to its structure, and once a molecule has been synthesized, all subsequent studies along the development path are focused only on assessing and understanding its properties in greater detail."

Our news journalists obtained a quote from the research from Bristol-Myers Squibb, "Unfortunately, a full prediction of the biological properties of a molecule from an analysis of its 2-or 3-dimensional structure is currently beyond our expertise. This backdrop mandates that considerable care be taken at the design stage if a molecule is to be successful in testing a mechanistic concept underlying a disease process and to progress into late stage clinical trials and, ultimately, marketing approval. While there are multiple potential causes of candidate
attrition, an introspective analysis of drug design practices over the past decade has focused attention on the perception that contemporary molecules are unnecessarily obese, burdened by high molecular weight and excessive lipophilicity. This practice is believed to have its roots in the singular pursuit of enhancing potency during lead optimization rather than adopting a more holistic approach to drug design that gives broader consideration to how structural features affect developability properties. In an effort to provide the medicinal chemistry community with practical guideposts to enhancing compound quality in the drug design phase and which can readily be applied, a series of efficiency indices have been proposed that attempt to define aspects of compound quality in the context of a series of physicochemical parameters. Of these metrics, lipophilic ligand efficiency (LLE or LipE), which provides an index of the dependence of the potency of a molecule on its intrinsic lipophilicity, has been characterized as the most robust metric that has potential for broad-based application. In this review, after describing the background literature behind the derivation of efficiency metrics and approaches to assessing compound aesthetics, synopses of some recent practical application in lead optimization campaigns are presented. However, molecules that fall into space beyond that associated with traditional drug-like properties are an important part of the current and future landscape, exemplified by the summary of direct acting hepatitis C virus NS3 and NS5A inhibitors that have transformed clinical therapy for this chronic disease."

According to the news editors, the research concluded: "While drug development in nontraditional drug-like space is more challenging and the rules for compound quality will be different with much still to be understood, careful and disciplined drug design practices will be an essential element of success."

Our news journalists report that additional information may be obtained by contacting N.A. Meanwell, Dept. of Discovery Chemistry, Bristol-Myers Squibb Research & Development, Wallingford, Connecticut 06492, United States.

Drugs and Therapies - Toxicology and Applied Pharmacology

Researchers from Bristol-Myers Squibb Report Details of New Studies and Findings in the Area of Toxicology and Applied Pharmacology (MicroRNA as biomarkers of mitochondrial toxicity)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Drugs and Therapies - Toxicology and Applied Pharmacology have been presented. According to news reporting from Mount Vernon, Iowa, by
NewsRx journalists, research stated, "Mitochondrial toxicity can be difficult to detect as most cells can tolerate reduced activity as long as minimal capacity for function is maintained. However, once minimal capacity is lost, apoptosis or necrosis occurs quickly."

The news correspondents obtained a quote from the research from Bristol-Myers Squibb, "Identification of more sensitive, early markers of mitochondrial toxicity was the objective of this work. Rotenone, a mitochondrial complex I inhibitor, and 3-nitropropionic acid (3-NP), a mitochondrial complex II inhibitor, were administered daily to male Sprague-Dawley rats at subcutaneous doses of 0.1 or 0.3 mg/kg/day and intraperitoneal doses of 5 or 10 mg/kg/day, respectively, for 1 week. Samples of kidney, skeletal muscle (quadriceps femoris), and serum were collected for analysis of mitochondrial DNA (mtDNA) copy number and microRNA (miRNA) expression patterns. MtDNA was significantly decreased with administration of rotenone at 03 mg/kg/day and 3-NP at 5 and 10 mg/kg/day in the quadriceps femoris and with 3-NP at 10 mg/kg/day in the kidney. Additionally, rotenone and 3-NP treatment produced changes to miRNA expression that were similar in direction (i.e. upregulation, downregulation) to those previously linked to mitochondrial functions, such as mitochondrial damage and biogenesis (miR-122, miR-202-3p); regulation of ATP synthesis, abolished oxidative phosphorylation, and loss of membrane potential due to increased reactive oxygen species (ROS) production (miR-338-5p, miR-546, miR-34c); and mitochondrial DNA damage and depletion (miR-546)."

According to the news reporters, the research concluded: "These results suggest that miRNAs may be sensitive biomarkers for early detection of mitochondrial toxicity."

For more information on this research see: MicroRNA as biomarkers of mitochondrial toxicity. Toxicology and Applied Pharmacology, 2016;312():26-33. Toxicology and Applied Pharmacology can be contacted at: Academic Press Inc Elsevier Science, 525 B St, Ste 1900, San Diego, CA 92101-4495, USA. Membrane Proteins - Immunologic Receptors

Researchers from British Columbia Cancer Research Center Report Findings in Immunologic Receptors (Oncofetal Chondroitin Sulfate Glycosaminoglycans Are Key Players in Integrin Signaling and Tumor Cell Motility)
A new study on Membrane Proteins - Immunologic Receptors is now available. According to news reporting originating in Vancouver, Canada, by NewsRx journalists, research stated, "Many tumors express proteoglycans modified with oncofetal chondroitin sulfate glycosaminoglycan chains (ofCS), which are normally restricted to the placenta. However, the role of ofCS in cancer is largely unknown."

The news reporters obtained a quote from the research from British Columbia Cancer Research Center, "The function of ofCS in cancer was analyzed using the recombinant ofCS-binding VAR2CSA protein (rVAR2) derived from the malaria parasite, Plasmodium falciparum. We demonstrate that ofCS plays a key role in tumor cell motility by affecting canonical integrin signaling pathways. Binding of rVAR2 to tumor cells inhibited the interaction of cells with extracellular matrix (ECM) components, which correlated with decreased phosphorylation of Src kinase. Moreover, rVAR2 binding decreased migration, invasion, and anchorage-independent growth of tumor cells in vitro. Mass spectrometry of ofCS-modified proteoglycan complexes affinity purified from tumor cell lines on rVAR2 columns revealed an overrepresentation of proteins involved in cell motility and integrin signaling, such as integrin-beta 1 (ITGB1) and integrin-alpha 4 (ITGA4). Saturating concentrations of rVAR2 inhibited downstream integrin signaling, which was mimicked by knockdown of the core chondroitin sulfate synthesis enzymes beta-1,3-glucuronyltransferase 1 (B3GAT1) and chondroitin sulfate N-acetylgalactosaminyltransferase 1 (CSGALNACT1). The ofCS modification was highly expressed in both human and murine metastatic lesions in situ and preincubation or early intravenous treatment of tumor cells with rVAR2 inhibited seeding and spreading of tumor cells in mice. This was associated with a significant increase in survival of the animals."

According to the news reporters, the research concluded: "These data functionally link ofCS modifications with cancer cell motility and further highlights ofCS as a novel therapeutic cancer target."

For more information on this research see: Oncofetal Chondroitin Sulfate Glycosaminoglycans Are Key Players in Integrin Signaling and Tumor Cell Motility. Molecular Cancer Research, 2016;14(12):1288-1299. Molecular Cancer Research can be contacted at: Amer Assoc Cancer Research, 615 Chestnut St, 17TH Floor, Philadelphia, PA 19106-4404, USA. Researchers from Brock University Describe Findings in Spinal Cord Injury (Non-invasive electrocardiographic assessments of cardiac autonomic modulation in individuals with spinal cord injury)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Central Nervous System Diseases and Conditions - Spinal Cord Injury are discussed in a new report. According to news originating from St. Catharines, Canada, by NewsRx correspondents, research stated, "Review. The purpose of this review is to discuss the utility of linear and non-linear heart rate variability (HRV) as well as the QT-variability index (QTVI) as indices of cardiac autonomic control in individuals with spinal cord injury (SCI)."

Our news journalists obtained a quote from the research from Brock University, "Brock University, Department of Kinesiology, St Catharines, Ontario, Canada. Brock-Niagara Centre for Health and Well-being, St Catharines, Ontario, Canada. Literature review. Non-invasive markers determined from the electrocardiogram, such as linear and non-linear HRV, and, more recently, the QTVI have all shown some promise as indices of cardiac autonomic regulation in the SCI population. However, there are inconsistencies in the literature that call to question their true validity in this regard. Studies using pharmacological blockade, sympathetic manoeuvres and exercise suggest that both linear and non-linear HRV reflect cardiac parasympathetic activity, whereas their ability to quantify cardiac sympathetic outflow remains uncertain."

According to the news editors, the research concluded: "The QTVI, although a novel method, correlates with both limbs of the autonomic nervous system and therefore may hold value as a measure of both cardiac sympathetic and parasympathetic activity in individuals with SCI; however, more research is required to confirm its utility."

The news correspondents report that additional information may be obtained from H. Sharif, Dept. of Kinesiology, Brock University, St Catharines, Ontario, Canada. Additional authors for this research include P.J. Millar, A.V. Incognito and D.S Ditor.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1038/sc.2015.207. This DOI is a link to an online electronic document that is either free or for purchase.

Researchers from Brussels Free University Describe Findings in Tuberculosis (Effects of Lipid-Lowering Drugs on Vancomycin Susceptibility of Mycobacteria)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Mycobacterium Infections - Tuberculosis. According to news reporting out of Brussels, Belgium, by NewsRx editors, research stated, "Tuberculosis is still a cause of major concern, partly due to the emergence of multidrug-resistant strains. New drugs are therefore needed."

Our news journalists obtained a quote from the research from Brussels Free University, "Vancomycin can target mycobacteria with cell envelope deficiency. In this study, we used a vancomycin susceptibility assay to detect drugs hampering lipid synthesis in Mycobacterium bovis BCG and in Mycobacterium tuberculosis. We tested three drugs already used to treat human obesity: tetrahydrolipstatin (THL), simvastatin, and fenofibrate. Only vancomycin and THL were able to synergize on M. bovis BCG and on M. tuberculosis, although mycobacteria could also be inhibited by simvastatin alone. Lipid analysis allowed us to identify several lipid modifications in M. tuberculosis H37Rv treated with those drugs. THL treatment mainly reduced the phthiocerol dimycocerosate (PDIM) content in the mycobacterial cell wall, providing an explanation for the synergy, since PDIM deficiency has been related to vancomycin susceptibility. Proteomic analysis suggested that bacteria treated with THL, in contrast to bacteria treated with simvastatin, tried to recover, inducing, among other reactions, lipid synthesis."

According to the news editors, the research concluded: "The combination of THL and vancomycin should be considered a promising solution in developing new strategies to treat multidrug-resistant tuberculosis."

Our news journalists report that additional information may be obtained by contacting V. Fontaine, Brussels Free University, Unit Pharmaceut Microbiol & Hyg, Brussels, Belgium. Additional authors for this research include F. Laval, M. Daffe, O. Denis, R. Frita, A. Baulard, R. Wattiez, P. Lefevre and V. Fontaine.

Researchers from Brussels Free University Report on Findings in Kidney Function (Chronic kidney disease as major determinant of the renal risk related to on-pump cardiac surgery: a single-center cohort study)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Gastroenterology - Kidney Function is now available. According to news reporting originating from Brussels, Belgium, by NewsRx correspondents, research stated, "Cardiac surgery-associated acute kidney injury (CSA-AKI) is a common complication and is associated with the poorest outcomes. Therefore, early prediction of CSA-AKI remains a major issue."

Our news editors obtained a quote from the research from Brussels Free University, "Severity scores such as the STS score could estimate the risk of AKI preoperatively. The main objective of this study was to evaluate the risk factors of on-pump CSA-AKI and to assess the performance of the STS score in order to predict CSA-AKI. We identified 252 patients with on-pump cardiac surgery, and the STS score was defined retrospectively. AKI occurred in 14.6% (n = 37/252) of patients and renal replacement therapy was required in 21.6% of AKI (n = 8/37). CSA-AKI was associated with 35.1% in-hospital mortality (vs. 1.4%) and nearly doubled length of stay (14.5 vs. 8.0 d). The risk of CSA-AKI was mainly determined by preoperative morbidities such as chronic kidney disease, peripheral vascular disease, and severe congestive heart failure. Long cardio-pulmonary bypass time was also a determinant. CSA-AKI+patients exhibited higher STS renal risk (5.6% vs. 2.0%; p< 0.0001), resulting in a good discrimination between AKI+and AKI- patients (area under curve [AUC] 0.80). Interestingly, a basal renal function <= 55 ml/ min/ 1.73m(2) was as good as the STS score to predict CSA-AKI (AUC 0.75; P 0.26). On-pump CSA-AKI was observed in nearly 15% of cases and was associated with poorer outcomes."

According to the news editors, the research concluded: "Interestingly, the risk of CSA-AKI could be estimated preoperatively, thanks to the basal renal function, which exhibited an equal performance to the STS score."

The news editors report that additional information may be obtained by contacting J.M. Hougardy, Brussels Free University, Hopital Erasme, Dept. of Nephrol, B-1070 Brussels, Belgium. Additional authors for this research include P. Revercez, A. Pourcelet, B. El Oumeiri, J. Racape, A. Le Moine, F. Vanden Eynden and D. De Backer.

Researchers from Cancer Hospital Describe Findings in Pancreaticoduodenectomy (Widespread lymph node recurrence of major duodenal papilla cancer following pancreaticoduodenectomy)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Surgery - Pancreaticoduodenectomy. According to news reporting originating in Chengdu, People's Republic of China, by NewsRx journalists, research stated, "Major duodenal papilla cancer (MDPC) represents the primary type of duodenal cancer, and is typically considered a periampullary carcinoma as most tumors arise in this region. This report describes an extremely rare case involving a patient with rapidly and extensively recurrent MDPC following pancreaticoduodenectomy, who achieved complete response by concurrent image-guided radiation and intravenous oxaliplatin plus oral capecitabine therapies."

The news reporters obtained a quote from the research from Cancer Hospital, "The patient was a 50-year-old female who was admitted to our hospital 6 wk after resection for MDPC for evaluation of a nontender and enlarged node in the left side of her neck. After clinical work-up, the patient was diagnosed with postoperatively recurrent MDPC with widespread lymph node metastases at the bilateral cervix, mediastinum, abdominal cavity, and retroperitoneal area. She was administered whole field image-guided radiation therapy along with four cycles of the intravenous oxaliplatin plus oral capecitabine regimen. A complete response by positron emission tomography with 18-fluorodeoxyglucose was observed 4 months after treatment."

According to the news reporters, the research concluded: "The patient continues to be disease-free 2 years after the diagnosis of recurrence."

Our news correspondents report that additional information may be obtained by contacting B.S. Li, Bai-Sen Li, Ming-Yong Xiao, Jian Wang, Dept. of Radiation Oncology, Sichuan Cancer Hospital and Institute, Chengdu 610041, Sichuan Province, People's Republic of China. Additional authors for this research include H. Shi, M. Wen, M.Y. Xiao and J. Wang.

Researchers from Cancer Institute Detail New Studies and Findings in the Area of Lung Cancer (Lung cancer biomarkers, targeted therapies and clinical assays)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Oncology - Lung Cancer. According to news reporting originating in Charlotte, North Carolina, by NewsRx journalists, research stated, "Until recently, the majority of genomic cancer research has been in discovery and validation; however, as our knowledge of tumor molecular profiling improves, the idea of genomic application in the clinic becomes increasingly tangible, paralleled with the drug development of newer targeted therapies. A number of profiling methodologies exist to identify biomarkers found within the patient (germ-line DNA) and tumor (somatic DNA)."

The news reporters obtained a quote from the research from Cancer Institute, "Subsequently, commercially available clinical assays to test for both germ-line and somatic alterations that are prognostic and/or predictive of disease outcome, toxicity or treatment response have significantly increased. This review aims to summarize clinically relevant cancer biomarkers that serve as targets for therapy and their potential relationship to lung cancer."

According to the news reporters, the research concluded: "In order to realize the full potential of genomic cancer medicine, it is imperative that clinicians understand these intricate molecular pathways, the therapeutic implication of mutations within these pathways, and the availability of clinical assays to identify such biomarkers."

Our news correspondents report that additional information may be obtained by contacting J.N. Patel, Levine Cancer Institute, Carolinas HealthCare System, Charlotte, NC, United States. Additional authors for this research include J.L. Ersek and E.S Kim.

Keywords for this news article include: Genetics, Oncology, Charlotte, Lung Cancer, United States, North Carolina, Article Review, Lung Neoplasms, North and Central America, Diagnostics and Screening.

Researchers from Capital Medical University Provide Details of New Studies and Findings in the Area of HIV/AIDS and Cytomegalovirus (Frosted branch angiitis in an AIDS patient with cytomegalovirus retinitis)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Opportunistic Infections - HIV/AIDS and Cytomegalovirus. According to news reporting originating in Beijing, People's Republic of China, by NewsRx journalists, research stated, "A case of frosted branch angiitis in an AIDS patient with cytomegalovirus (CMV) retinitis is reported."
The news reporters obtained a quote from the research from Capital Medical University. "The use of PCR techniques for CMV DNA detection in intraocular fluid was helpful in this situation."

According to the news reporters, the research concluded: "The appropriate therapy was given promptly due to the timely diagnosis based on this assay."

Our news correspondents report that additional information may be obtained by contacting H.Y. Sun, Capital Med Univ, Natl Clin Key Dept. of Infect Dis, Beijing DiTan Hosp, Beijing 100015, People's Republic of China. Additional authors for this research include J.H. Wu, H.Y. Sun, Q.S. You and D. Li.

Researchers from Capital Medical University Report Findings in Hermansky-Pudlak Syndrome (NGS-based 100-gene panel of hypopigmentation identifies mutations in Chinese Hermansky-Pudlak syndrome patients)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Nutritional and Metabolic Diseases and Conditions - Hermansky-Pudlak Syndrome. According to news reporting from Beijing, People's Republic of China, by NewsRx journalists, research stated, "Hermansky-Pudlak syndrome (HPS) is a rare recessive disorder characterized by hypopigmentation, bleeding diathesis, and other symptoms due to multiple defects in lysosome-related organelles. Ten HPS subtypes have been identified with mutations in HPS1 to HPS10."

Financial supporters for this research include National Natural Science Foundation of China, Natural Science Foundation of Beijing Municipality, Ministry of Science and Technology of the People's Republic of China.

The news correspondents obtained a quote from the research from Capital Medical University, "Only four patients with HPS-1 have been reported in Chinese population. Using next-generation sequencing (NGS), we have screened 100 hypopigmentation genes and identified four HPS-1, two HPS-3, one HPS-5, and three HPS-6 in Chinese HPS patients with
typical ocular or oculocutaneous albinism and the absence of platelet dense granules together with other variable phenotypes. All these patients except one homozygote were compound heterozygotes. Among these mutations, 14 were previously unreported alleles (four in HPS1, three in HPS3, two in HPS5, five in HPS6). Our results demonstrate the feasibility and utility of NGS-based panel diagnostics for HPS.

According to the news reporters, the research concluded: "Genotyping of HPS subtypes is a prerequisite for intervention of subtype-specific symptoms."

Our news journalists report that additional information may be obtained by contacting A.H. Wei, Capital Med Univ, Beijing Tongren Hosp, Dept. of Dermatol, Beijing, People's Republic of China. **Heart Disorders and Diseases - Heart Disease**

**Researchers from Capital Medical University Report New Studies and Findings in the Area of Heart Disease [Genetic Polymorphism of CYP2C19 and Inhibitory Effects of Ticagrelor and Clopidogrel Towards Post-Percutaneous Coronary Intervention (PCI) ...]**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Heart Disorders and Diseases - Heart Disease have been published. According to news reporting out of Beijing, People's Republic of China, by NewsRx editors, research stated, "The aim of this study was to observe the effects of genetic polymorphism of CYP2C19 on inhibitory effects of ticagrelor (Tic) and clopidogrel (Clo) towards post-percutaneous coronary intervention (PCI) platelet aggregation (IPA) and major cardiovascular events (MACE) in patients with acute coronary syndromes (ACS). From August 2013 to March 2014, 166 patients with ACS undergoing PCI were selected."

Our news journalists obtained a quote from the research from Capital Medical University. "The patients were randomly grouped into the Tic group and the Clo group. IPA was detected by thromboelastography (TEG) at 1 week after taking the pills. Genotyping of CYP2C19 gene was determined by analysis of gene sequence detection. Patients were followed up for 1 month and MACE was observed. The total IPA in the Clo group was significantly
increased compared with the Tic group (P <0.05). The IPAs in the 3 subgroups of Clo group were all significantly increased compared with the 3 subgroups of the Tic group (all P<0.05). MACE was not significantly different between Clo and Tic groups (P >0.05). MACE had no significant difference among the 3 subgroups of the Tic group (P >0.05). MACE in the low metabolism subgroup of the Clo group was significantly increased compared with the fast metabolism subgroup and middle metabolism subgroup of Clo group (P <0.05). MACE was not significant different between the fast metabolism subgroup and the middle metabolism subgroup of the Clo group (P >0.05). MACE in the low metabolism subgroup of the Tic group was significantly decreased compared with the low metabolism subgroup of the Clo group (P <0.05).

According to the news editors, the research concluded: "Ticagrelor has a better effect on inhibition platelet aggregation than Clopidogrel in ACS patients undergoing PCI."

For more information on this research see: Genetic Polymorphism of CYP2C19 and Inhibitory Effects of Ticagrelor and Clopidogrel Towards Post-Percutaneous Coronary Intervention (PCI) Platelet Aggregation in Patients with Acute Coronary Syndromes. Medical Science Monitor, 2016;22():4929-4936. Medical Science Monitor can be contacted at: Int Scientific Literature, Inc, 361 Forest Lane, Smithtown, NY 11787, USA.

treatment of acute stroke. Search methods We searched the Cochrane Stroke Group Trials Register (accessed March 2016), the Cochrane Central Register of Controlled Trials (CENTRAL) 2016, Issue 3, part of the Cochrane Library (accessed March 2016), MEDLINE (from 1949 to March 2016), Embase (from 1980 to March 2016), CINAHL (from 1982 to March 2016), AMED (from 1985 to March 2016), and 11 Chinese databases (accessed March 2016). In an effort to identify further published, unpublished, and ongoing trials we searched ongoing trials registers, reference lists, and relevant conference proceedings, and contacted authors and pharmaceutical companies. Selection criteria We included randomized controlled trials (RCTs) investigating GABA receptor agonists versus placebo for people with acute stroke (within 12 hours after stroke onset), with the primary outcomes of efficacy and safety. Data collection and analysis Two review authors independently screened the titles and abstracts of identified records, selected studies for inclusion, extracted eligible data, cross-checked the data for accuracy, and assessed the risk of bias. We included five trials with 3838 participants (3758 analyzed). The methodological quality of the included trials was generally good, with an unclear risk for selection bias only. Four trials (N = 2909) measured death and dependency at three months for chlormethiazole versus placebo; pooled results did not find a significant difference (risk ratio (RR) 1.03, 95% confidence interval (CI) 0.96 to 1.11). One trial (N = 849) measured this outcome for diazepam versus placebo (RR 0.94, 95% CI 0.82 to 1.07). The most frequent adverse events related to chlormethiazole were somnolence (RR 4.56, 95% CI 3.50 to 5.95; two trials; N = 2527) and rhinitis (RR 4.75, 95% CI 2.67 to 8.46; two trials; N = 2527). Authors' conclusions This review provides moderate-quality evidence that fails to support the use of GABA receptor agonists (chlormethiazole or diazepam) for the treatment of people with acute stroke. More well-designed RCTs with large samples of participants with total anterior circulation syndrome are required to determine if there are benefits for this subgroup."

According to the news editors, the research concluded: "Somnolence and rhinitis are frequent adverse events related to chlormethiazole."

For more information on this research see: Gamma aminobutyric acid (GABA) receptor agonists for acute stroke. Cochrane Database of Systematic Reviews, 2016;(10):89-134. Cochrane Database of Systematic Reviews can be contacted at: Wiley-Blackwell, 111 River St, Hoboken 07030-5774, NJ, USA.

The news correspondents report that additional information may be obtained from J. Liu, Capital Med Univ, Xuanwu Hosp, Dept. of Neurol, Beijing 100053, People's Republic of China. Additional authors for this research include L.N. Wang, X. Ma and X.M. Ji.

Aortic Dissection

Researchers from Capital Medical University Report on Findings in Aortic Dissection (Noninvasive Positive-Pressure Ventilation in Treatment of Hypoxemia After Extubation Following Type-A Aortic

Obesity, Fitness & Wellness Week - January 14, 2017 - Page 6885
Dissection)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Aortic Dissection have been published. According to news reporting originating from Beijing, People's Republic of China, by NewsRx correspondents, research stated, "To assess the efficacy of noninvasive positive pressure ventilation (NPPV) in improving hypoxemia after extubation for Stanford type-A aortic dissection and to compare NPPV using a mask or a helmet. Prospective, interventional study."

Our news editors obtained a quote from the research from Capital Medical University, "Department of Cardiac Surgery of the Beijing Anzhen Hospital, a tertiary university hospital. Patients experiencing hypoxemia within 24 hours after extubation for Stanford type-A aortic dissection. The patients were divided into the following 3 groups: high-flux inhalation of oxygen with a Venturi mask (control patients), NPPV with a mask (mask group), and NPPV with a helmet (helmet group) (n = 25/group). Data for blood gas analysis, vital signs, heart function, and complications were collected before the treatment, after 1 and 6 hours of treatment, and at the end of treatment. The oxygen partial pressure/fraction of inspired oxygenation index or PaO2/FIO(2) ratio and the oxygen partial pressure were higher and carbon dioxide partial pressure was lower in the mask and helmet groups compared with that of control patients. Compared with control patients and the mask group, the helmet group showed a slower heart rate, lower average arterial pressure, and improved left ventricular ejection fraction, leading to a lower incidence of reintubation and a shorter hospital stay."

According to the news editors, the research concluded: "NPPV with a helmet may quickly improve oxygen partial pressure, decrease carbon dioxide partial pressure, decrease the reintubation rate, and effectively shorten the hospital stay after extubation for Stanford type-A aortic dissection."

The news editors report that additional information may be obtained by contacting N. Liu, Capital Med Univ, Beijing Inst Heart Lung & Blood Vessel Dis, Beijing Anzhen Hosp, Center Cardiac Intens Care, Beijing 100029, People's Republic of China. Additional authors for this research include N. Liu, L.Z. Sun, Y. Zhou, Y. Yang, W. Shang and X.M. Li.

Researchers from Careggi Hospital Detail Findings in Atrial Fibrillation (Percutaneous left atrial appendage occlusion in patients with non-valvular atrial fibrillation: implantation and up to four years follow-up of the AMPLATZER Cardiac Plug)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Heart Disorders and Diseases - Atrial Fibrillation is now available. According to news reporting originating from Florence, Italy, by NewsRx correspondents, research stated, "Percutaneous left atrial appendage occlusion (LAAO) may be considered for stroke prophylaxis in patients with non-valvular atrial fibrillation (NVAF). Data on device implantation safety and feasibility and long-term follow-up are limited."

Our news editors obtained a quote from the research from Careggi Hospital, "LAAO was performed using the AMPLATZER Cardiac Plug (ACP) device in 134 NVAF patients with long-term OAC contraindication, with median (interquartile range) CHA2DS2-VASc and HAS-BLED scores of four (3-5) and three (2-3.75), respectively. Follow-up data were collected over a mean follow-up period of 680 days (range: 42 days to 4.3 years) comprising a total implant experience of 238 patient-years. Device implantation was successful in 95.5% of the procedures and associated with a rate of major procedural complications of 2.2%. At the most recent follow-up, almost all patients were receiving antiplatelet therapy. Ischaemic stroke was observed at an annual rate of 0.8% and the annual rate of any thromboembolic (TE) event was 2.5%. Major bleeding during follow-up occurred at an annual rate of 1.3%. LAAO is a safe and effective stroke prevention therapy in a high-risk NVAF cohort, both at implantation and over longer follow-up periods."

According to the news editors, the research concluded: "The long-term assessed ischaemic stroke rate in patients treated with LAAO is markedly reduced compared to the expected rate based on the patients' risk scores."

For more information on this research see: Percutaneous left atrial appendage occlusion in patients with non-valvular atrial fibrillation: implantation and up to four years follow-up of the AMPLATZER Cardiac Plug, Eurointervention, 2016;11(10):1188-94.

The news editors report that additional information may be obtained by contacting G. Santoro, Interventional Cardiology Unit, Careggi Hospital, Florence, Italy. Additional authors for this research include F. Meucci, M. Stolcova, M. Rezzaghi, F. Mori, C. Palmieri, U. Paradossi, L.E. Pastormerlo, G. Rosso and S. Berti.

Researchers from Carolinas Medical Center Report Recent Findings in Pneumonia (Antifungal use in immunocompetent, critically ill patients with pneumonia does not improve clinical outcomes)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Lung Diseases and Conditions - Pneumonia. According to news reporting out of Charlotte, North Carolina, by NewsRx editors, research stated, "To determine if treating bronchoalveolar lavage (BAL) culture-positive patients with antifungal therapy impacted mortality compared to not treating due to presumed colonization. We conducted a retrospective study of immunocompetent, critically ill adult patients from 2010 to 2014."

Our news journalists obtained a quote from the research from Carolinas Medical Center, "Patients with a BAL culture-positive for Candida or unspeciated yeast and a clinical suspicion of pneumonia were included. The treatment group received an antifungal agent for at least 5 days, and the control group received either no antifungal therapy or an antifungal agent for less than 48 h. Recruitment occurred in a 2:1 ratio of untreated versus treated patients. Seventy-five patients were included. In-hospital mortality was similar between treated and untreated groups (24% vs. 26%, P = 0.85). Length of stay and duration of mechanical ventilation also did not differ between the two groups. We did not observe a difference in mortality or clinical outcomes in patients treated with antifungal agents."

According to the news editors, the research concluded: "Presumptive antifungal therapy for BAL-positive Candida or yeast in immunocompetent patients did not result in improved clinical outcomes."

Our news journalists report that additional information may be obtained by contacting K.E. Martin, Carolinas Med Center, Charlotte, NC 28203, United States. Additional authors for this research include D.E. Kosmisky, M.A. Templin, T. Huynh, L.H. McCurdy, T.R. Pasquale and K.E. Martin.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1016/j.hrtlng.2016.08.002. This DOI is a link to an online electronic document that is either free or for purchase.

Researchers from Catholic University Report Details of New Studies and Findings in the Area of Gastrointestinal Neoplasms (Divergent gastrointestinal stromal tumors in syndromic settings)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Digestive System Diseases and Conditions - Gastrointestinal Neoplasms. According to news originating from Rome, Italy, by NewsRx correspondents, research stated, "The vast majority of gastrointestinal stromal tumors (GISTs) occur as sporadic tumors. Rarely, however, these neoplasms can arise in syndromic contexts."

Financial support for this research came from Universita Cattolica del Sacro Cuore. Our news journalists obtained a quote from the research from Catholic University, "Under these circumstances, GISTs are often multiple and associated with accompanying signs peculiar of the hosting syndrome. Moreover, syndromic GISTs themselves tend to show heterogeneous features depending on the underlying condition. Multiple inflammatory fibroid polyps (IFPs) and a jejunal spindle-cell GIST were resected in a germline PDGFRA-mutant individual. Although the association of IFP and GIST is typical of this genetic setting (PDGFRA mutations can in fact trigger both these tumor types), PDGFRA'mutant GISTs are usually epithelioid and gastric. This discrepancy was settled evidencing a somatic KIT mutation in the GIST. The awareness of possible somatic mutations can be critical in the management of high-risk/ malignant GISTs arising in syndromic settings."

According to the news editors, the research concluded: "GIST features unusual for a given GIST predisposing syndrome are a valuable tool in the hands of physicians for suspecting these 'extra' triggers, which could not be sought for once a diagnosis of GIST-prone syndrome is well established, in a bona fide cost/benefit perspective."

The news correspondents report that additional information may be obtained from R. Ricci, Catholic Univ, Dept. of Pathol, Rome, Italy. Additional authors for this research include M. Martini, T. Cenci, M.E. Riccioni, G. Maria, A. Cassano and L.M. Larocca.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1016/j.cancergen.2016.05.073. This DOI is a link to an online electronic document that is either free or for purchase.

Cardiovascular Diseases and Conditions - Systemic…

Researchers from Catholic University Report on Findings in Systemic Vasculitis [The prognostic significance of the Birmingham Vasculitis Activity Score (BVAS) with systemic vasculitis patients transferred to the intensive care unit (ICU)]

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Cardiovascular Diseases and Conditions - Systemic Vasculitis. According to news reporting originating in Rome, Italy, by NewsRx journalists, research stated, "Systemic vasculitides represent a heterogeneous group of diseases that share clinical features including respiratory distress, renal dysfunction, and neurologic disorders. These diseases may often cause life-threatening complications requiring admission to an intensive care unit (ICU)."

The news reporters obtained a quote from the research from Catholic University, "The aim of the study was to evaluate the validity and responsiveness of Birmingham Vasculitis Activity Score (BVAS) score to predict survival in patients with systemic vasculitides admitted to ICU. A retrospective study was carried out from 2004 to 2014 in 18 patients with systemic vasculitis admitted to 2 different Rheumatology divisions and transferred to ICU due to clinical worsening, with a length of stay beyond 24 hours. We found that ICU mortality was significantly associated with higher BVAS scores performed in the ward (P=0.01) and at the admission in ICU (P=0.01), regardless of the value of Acute Physiology And Chronic Health Evaluation (APACHE II) scores (P=0.50). We used receiver operator characteristic (ROC) curve analysis to evaluate the possible cutoff value for the BVAS in the ward and in ICU and we found that a BVAS >8 in the ward and that a BVAS > 10 in ICU might be a useful tool to predict in-ICU mortality. BVAS appears to be an excellent tool for assessing ICU modality risk of systemic vasculitides patients admitted to specialty departments."

According to the news reporters, the research concluded: "Our experience has shown that performing the assessment at admission to the ward is more important than determining the evaluation before the clinical aggravation causing the transfer to ICU."

For more information on this research see: The prognostic significance of the Birmingham Vasculitis Activity Score (BVAS) with systemic vasculitis patients transferred to the intensive care unit (ICU). Medicine, 2016;95(48):205-210. Medicine can be contacted at: Lippincott Williams & Wilkins, Two Commerce Sq, 2001 Market St, Philadelphia, PA 19103, USA. Researchers from Catholic University of Korea Report New Studies and Findings in the Area of Cardiology (3D printed complex tissue construct using stem cell-laden decellularized extracellular matrix bioinks for cardiac repair)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Cardiology have been presented. According to news reporting out of Seoul, South Korea, by NewsRx editors, research stated, "Stem cell therapy is a promising therapeutic method for the treatment of ischemic heart diseases; however, some challenges prohibit the efficacy after cell delivery due to hostile microenvironment of the injured myocardium. 3D printed pre-vascularized stem cell patch can enhance the therapeutic efficacy for cardiac repair through promotion of rapid vascularization after patch transplantation. In this study, stem cell-laden decellularized extracellular matrix bioinks are used in 3D printing of pre-vascularized and functional multi-material structures."

Financial supporters for this research include National Research Foundation of Korea, MSIP, DWC, Research Fund of Seoul St. Mary's Hospital, The Catholic University of Korea.

Our news journalists obtained a quote from the research from the Catholic University of Korea, "The printed structure composed of spatial patterning of dual stem cells improves cell-to-cell interactions and differentiation capability and promotes functionality for tissue regeneration. The developed stem cell patch promoted strong vascularization and tissue matrix formation in vivo. The patterned patch exhibited enhanced cardiac functions, reduced cardiac hypertrophy and fibrosis, increased migration from patch to the infarct area, neo-muscle and capillary formation along with improvements in cardiac functions."

According to the news editors, the research concluded: "Therefore, pre-vascularized stem cell patch provides cardiac niche-like microenvironment, resulting in beneficial effects on cardiac repair."

For more information on this research see: 3D printed complex tissue construct using stem cell-laden decellularized extracellular matrix bioinks for cardiac repair. Biomaterials, 2017;112():264-274. Biomaterials can be contacted at: Elsevier Sci Ltd, The Boulevard, Langford Lane, Kidlington, Oxford OX5 1GB, Oxon, England. (Elsevier - www.elsevier.com; Biomaterials - www.journals.elsevier.com/biomaterials/)

Researchers from Catholic University of Leuven Report Details of New Studies and Findings in the Area of Endotoxins (MMP-3 Deficiency Alleviates Endotoxin-Induced Acute Inflammation in the Posterior Eye Segment)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Biological Factors - Endotoxins have been presented. According to news reporting from Leuven, Belgium, by NewsRx journalists, research stated, "Matrix metalloproteinase-3 (MMP-3) is known to mediate neuroinflammatory processes by activating microglia, disrupting blood-central nervous system barriers and supporting neutrophil influx into the brain. In addition, the posterior part of the eye, more specifically the retina, the retinal pigment epithelium (RPE) and the blood-retinal barrier, is affected upon neuroinflammation, but a role for MMP-3 during ocular inflammation remains elusive."

The news correspondents obtained a quote from the research from the Catholic University of Leuven, "We investigated whether MMP-3 contributes to acute inflammation in the eye using the endotoxin-induced uveitis (EIU) model. Systemic administration of lipopolysaccharide induced an increase in MMP-3 mRNA and protein expression level in the posterior part of the eye. MMP-3 deficiency or knockdown suppressed retinal leukocyte adhesion and leukocyte infiltration into the vitreous cavity in mice subjected to EIU. Moreover, retinal and RPE mRNA levels of intercellular adhesion molecule 1 (Icam1), interleukin 6 (Il6), cytokine-inducible nitrogen oxide synthase (Nos2) and tumor necrosis factor alpha (Tnf alpha), which are key molecules involved in EIU, were clearly reduced in MMP-3 deficient mice. In addition, loss of MMP-3 repressed the upregulation of the chemokines monocyte chemoattractant protein (MCP)-1 and (C-X-C motif) ligand 1 (CXCL1)."

According to the news reporters, the research concluded: "These findings suggest a contribution of MMP-3 during EIU, and its potential use as a therapeutic drug target in reducing ocular inflammation."

For more information on this research see: MMP-3 Deficiency Alleviates Endotoxin-Induced Acute Inflammation in the Posterior Eye Segment. *International Journal of Molecular Sciences*, 2016;17(11):996-1018. *International Journal of Molecular Sciences* can be contacted at: Mdp Ag, St Alban-Anlage 66, Ch-4052 Basel, Switzerland.

Our news journalists report that additional information may be obtained by contacting I. Van Hove, Catholic University of Leuven, Dept. of Neurosci, Lab Expt Ophthalmol, B-3000 Leuven, Belgium. Researchers from Catholic University of Leuven School of Medicine Detail Findings in Thyroid Cancer (Post-Chernobyl incidence of papillary thyroid cancer among Belgian children less than 15 years of age in April 1986: a 30-year surgical ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Oncology - Thyroid Cancer. According to news reporting originating from Yvoir, Belgium, by NewsRx correspondents, research stated, "We raised the question of a possible relationship in Belgium between the occurrence of papillary thyroid carcinoma (PTC) and age of children (< 15 years) at the time of the Chernobyl nuclear plant accident in April 1986. Referral university centre for endocrine surgery."

Our news editors obtained a quote from the research from the Catholic University of Leuven School of Medicine, "Thirty-year prospective study of the experience of a surgical team with PTC since the Chernobyl accident, taken out of 2349 patients operated on for any thyroid lesions from April 1986 to April 2015, comparing the incidence of PTC by age groups. Main outcome measurement: Comparison of PTC incidence in patients >15 years (group A) and children < 15 years (group B) in April 1986. Out of a total of 2349 patients having undergone thyroid surgery for all types of lesions during 30 year after Chernobyl and born before April 1986, 2164 were > 15 years of age at the time of the nuclear accident (group A) and 175 developed PTC (8.1%) compared to 36 PTC (19.5%) that occurred in 185 children < 15 years of age (group B) in April 1986 (p <0.001). Radiation exposure affected residents of countries (including Belgium) well beyond Ukraine and Belarus. This was demonstrated by a 1990 meteorological report. Over 30 years, there has been a persistent higher incidence of PTC among Belgian children below the age of 15 years at the time of the Chernobyl accident."

According to the news editors, the research concluded: "This relationship with age has even been strengthened by the implementation of more sophisticated immunohistochemical biomarkers diagnostic technology since April 2011."

The news editors report that additional information may be obtained by contacting L.A. Michel, Univ Louvain Med Sch, Mont Godinne Univ Hosp, Serv Surg Endocrinol, B-5100 Yvoir, Belgium. Additional authors for this research include J. Donckier, A. Rosiere, C. Fervaille, J. Lemaire and C. Bertrand.

Keywords for this news article include: Yvoir, Belgium, Europe, Papillary Thyroid Carcinoma, Papillary Thyroid Cancer, Thyroid Neoplasms, Oncology, Catholic University of Leuven School of Medicine.

Researchers from Cedars-Sinai Heart Institute Describe Findings in Cardiovascular Interventions (Feasibility and safety of balloon-expandable transcatheter aortic valve implantation with moderate or without predilatation)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Health and Medicine - Cardiovascular Interventions is now available. According to news reporting originating from Los Angeles, California, by NewsRx correspondents, research stated, "Aortic valve preparation by performing balloon aortic valvuloplasty (BAV) has always been considered mandatory during transcatheter aortic valve implantation (TAVI) procedures. We aimed to investigate the feasibility and safety of performing balloon-expandable TAVI with moderate or with no predilatation (PD)."

Our news editors obtained a quote from the research from Cedars-Sinai Heart Institute, "Overall, 121 patients underwent TAVI with no PD and 392 with moderate PD. TAVI endpoints and adverse events were considered according to the Valve Academic Research Consortium (VARC)-2 definitions. Device success for the entire cohort was 95.1%. Post-dilatation was performed in nine patients in the no PD group (7.4%) and in 40 patients in the moderate PD group (10.2%) (p=0.06). Total fluoroscopy time and the amount of contrast used were lower in the no PD group. All-cause mortality up to 30 days was 3.3% in the no PD group vs. 3.6% in the moderate PD group (p=0.89). VARC-2 defined complication rates at 30 days including cerebrovascular accident (CVA)/transient ischaemic attack (TIA) were similar between groups. Overall, there was no significant difference in survival rates between the two groups (HR 1.33, 95% CI: 0.75-2.35; p=0.34). Balloon-expandable TAVI with moderate or without balloon PD is feasible and safe."

According to the news editors, the research concluded: "The omission of PD in appropriate cases was associated with reduced fluoroscopy time without affecting procedural success."

The news editors report that additional information may be obtained by contacting Y. Abramowitz, Cedars-Sinai Heart Institute, Los Angeles, CA, United States. Additional authors for this research include H. Jilaihawi, T. Chakravarty, M. Kashif, G. Matar, B. Hariri, J. Patel, R.P. Sharma, W. Cheng and R.R Makkar.

Researchers from Center Hospitalier Lyon Sud Report New Studies and Findings in the Area of Cancer Research (Conflicting Signals for Cancer Treatment)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Oncology - Cancer Research have been published. According to news reporting originating in Pierre Benite, France, by NewsRx journalists, research stated, "Next-generation sequencing technologies have provided us with a precise description of the mutational burden of cancers, making it possible to identify targetable oncogene addictions. However, the emergence of resistant clones is an inevitable limitation of therapies targeting these addictions."

The news reporters obtained a quote from the research from Center Hospitalier Lyon Sud, "Alternative approaches to cancer treatment are therefore required. We propose here a novel approach, based on the notion of conflicting signals and on a phenotypic description of cancer cells. 'Phenotype' is an inherently complex notion that we describe in the conceptual framework of the epigenetic landscape, with a view to bridging the gap between theory and practice at the patient's bedside."

According to the news reporters, the research concluded: "By passing from theory to the description of several examples, we will illustrate how this approach can facilitate data analysis and the design of new strategies for cancer treatment."

For more information on this research see: Conflicting Signals for Cancer Treatment. *Cancer Research*, 2016;76(23):6768-6773. *Cancer Research* can be contacted at: Amer Assoc Cancer Research, 615 Chestnut St, 17TH Floor, Philadelphia, PA 19106-4404, USA. Immunology

Researchers from Center for Research and Advanced Studies of the National Polytechnic Institute (CINVESTAV) Report Details of New Studies and Findings in the Area of Immunology (Inflammasomes and its importance in viral infections)
2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Immunology. According to news reporting originating in Mexico City, Mexico, by NewsRx journalists, research stated, "A complex interplay between pathogen and host determines the immune response during viral infection. A set of cytosolic sensors are expressed by immune cells to detect viral infection."

Financial support for this research came from CONACYT.

The news reporters obtained a quote from the research from the Center for Research and Advanced Studies of the National Polytechnic Institute (CINVESTAV), "NOD-like receptors (NLRs) comprise a large family of intracellular pattern recognition receptors. Members of the NLR family assemble into large multiprotein complexes, termed inflammasomes, which induce downstream immune responses to specific pathogens, environmental stimuli, and host cell damage. Inflammasomes are composed of cytoplasmic sensor molecules such as NLRP3 or absent in melanoma 2 (AIM2), the adaptor protein ASC (apoptosis-associated speck-like protein containing caspase recruitment domain), and the effector protein procaspase-1. The inflammasome operates as a platform for caspase-1 activation, resulting in caspase-1-dependent proteolytic maturation and secretion of interleukin (IL)-1 beta and IL-18. This, in turn, activates the expression of other immune genes and facilitates lymphocyte recruitment to the site of primary infection, thereby controlling invading pathogens. Moreover, inflammasomes counter viral replication and remove infected immune cells through an inflammatory cell death, program termed as pyroptosis. As a countermeasure, viral pathogens have evolved virulence factors to antagonise inflammasome pathways. In this review, we discuss the role of inflammasomes in sensing viral infection as well as the evasion strategies that viruses have developed to evade inflammasome-dependent immune responses."

According to the news reporters, the research concluded: "This information summarises our understanding of host defence mechanisms against viruses and highlights research areas that can provide new approaches to interfere in the pathogenesis of viral diseases."

For more information on this research see: Inflammasomes and its importance in viral infections. Immunologic Research. 2016;64(5-6):1101-1117. Researchers from Centers for Disease Control and Prevention Report Recent Findings in Cardiovascular Research (Modification of the effects of air pollutants on mortality by temperature: A systematic review and meta-analysis)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Cardiovascular Research have been presented. According to news reporting originating in Beijing, People's Republic of China, by NewsRx journalists, research stated. "Temperature extremes and air pollution both pose significant threats to human health, but it remains uncertain whether pollutants’ effects on mortality are modified by temperature levels. In this review, we summarized epidemiologic evidence on the modification by temperature of the acute effects of air pollutants on non-accidental and cardiovascular mortality."

Funders for this research include National Basic Research Program of China, State Key Laboratory for Infectious Disease Prevention and Control.

The news reporters obtained a quote from the research from Centers for Disease Control and Prevention, "The EMBASE, PubMed, ProQuest Dissertations and Theses, and Elsevier Science Direct databases were used to identify papers published up to 2nd December 2014. Studies with appropriate design, exposures and outcome indicators, quantitative estimates and high/intermediate quality were included. Twenty-one studies met the inclusion criteria, of which 12 reported the effects of PM10 on mortality modified by temperature, 10 studied O-3, and the rest examined NO2, SO2, PM2.5, PM10-2.5, CO and black smoke. We divided temperature into low, medium, and high categories as defined in each study. In high temperature days, a 10 μg/m(3) increment in PM10 concentration corresponded to pooled estimates of 0.78% (95% CI: 0.44%, 1.11%) and 1.28% (0.66%, 1.91%) increase in non-accidental and cardiovascular mortality, both statistically significantly higher than the estimates in medium temperature stratum. Pooled effects of O-3 on non-accidental mortality on low and high temperature days were increases of 0.48% (0.28%, 0.69%) and 0.47% (0.32%, 0.63%) respectively, for 10 μg/m(3) increase in exposure, both significantly higher than the increase of 0.20% (0.07%, 0.34%) on medium temperature days. The effect of O-3 on cardiovascular mortality was strongest on high temperature days with pooled estimate of 1.63% (1.14%, 2.13%). No significant interactions between SO2/NO2 and temperature were detected by meta-analysis. Other pollutants were not analyzed due to the lack of suitable studies. In summary, we observed interactions between high temperature and PM10 and O-3 in the effects on non-accidental and cardiovascular mortality."

According to the news reporters, the research concluded: "Low temperature modified the effects of air pollutants but not in a consistent fashion: the effect of PM10 on cardiovascular mortality was diminished but the association between O-3 and non-accidental mortality was strengthened."

For more information on this research see: Modification of the effects of air pollutants on mortality by temperature: A systematic review and meta-analysis. Oncology - Non-Small Cell Lung Cancer

Researchers from Central Hospital Report Recent Findings in Non-Small Cell Lung Cancer (The impact of epidermal growth factor receptor mutations on patterns of disease recurrence after chemoradiotherapy for locally advanced non-small cell lung...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Oncology - Non-Small Cell Lung Cancer are discussed in a new report. According to news reporting out of Mie, Japan, by NewsRx editors, research stated, "The purpose of this review was to evaluate the impact of epidermal growth factor receptor (EGFR) mutation status on disease recurrence in patients treated with chemoradiotherapy (CRT) for locally advanced non-small cell lung cancer (NSCLC). A literature search was conducted and a total of three studies were analyzed."

Our news journalists obtained a quote from the research from Central Hospital, "There was no significant difference in the objective response rate between the EGFR mutation group and the EGFR wild-type group (odds ratios [OR] 1.46, 95% CI, 0.79-2.70, P = 0.228), and there was no significant difference in the incidence of disease recurrence (OR 1.37, 95% CI, 0.68-2.75, P = 0.379) between the two groups. There were significant difference in the incidence of local/locoregional progression (LP) (OR 0.35, 95% CI, 0.18-0.71, P = 0.003) and distant progression (DP) (OR 2.97, 95% CI, 1.59-5.54, P< 0.001). Brain metastasis (BM) was one of the main recurrence patterns of DP, and the incidence was significantly higher in the EGFR mutant group (OR 2.75, 95% CI, 1.43-5.31, P = 0.003). There were no statistically significant heterogeneities in these pooled analyses. The patterns of recurrence after CRT for locally advanced NSCLC were different according to EGFR mutation status. LP after CRT in patients with EGFR mutation was less frequent, but the high incidence of DP, especially BM, continued to be the major problem. On the other hand, LP continued to be the major problem in EGFR wild-type patients."

According to the news editors, the research concluded: "In multimodality treatment for inoperable locally advanced NSCLC, we may need to consider different treatment strategies according to EGFR mutation status."

For more information on this research see: The impact of epidermal growth factor receptor mutations on patterns of disease recurrence after chemoradiotherapy for locally...

Our news journalists report that additional information may be obtained by contacting S. Ochiai, Matsusaka Cent Hosp, Dept. of Radiat Oncol, Matsusaka, Mie 5158566, Japan. **Oncology - Leukemia**

**Researchers from Central South University Describe Findings in Leukemia (STIP Regulates ERK1/2 Signaling Pathway Involved in Interaction with PP1 gamma in Lymphoblastic Leukemia)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Oncology - Leukemia is now available. According to news reporting originating from Changsha, People's Republic of China, by NewsRx correspondents, research stated, "Sip1/Tuftelin Interacting Protein (STIP) is highly conserved from Caenorhabditis elegans to Homo sapiens and has essential biological functions. However, its function in leukemia remains unknown."

Our news editors obtained a quote from the research from Central South University, "Clinic samples and cell model were used in this article to investigate the expression of STIP in lymphoblastic leukemia. The functional research of STIP was performed in ARH-77 by siRNA transfection, immunofluorescence, cell count, cell cycle analysis, qRT-PCR, sub-cellular fractionation assays, immunoprecipitation and western blotting. Here, we found that STIP is more highly expressed in both clinical lymphoblastic leukemia samples and cultured leukemia cells than in normal samples. Knockdown of STIP in B lymphoblastic leukemia ARH-77 cells leads to S phase arrest, lower cell proliferation rates, and suppressed AKT and ERK1/2 signaling pathways. Interestingly, when protein phosphatase was inhibited by Calyculin A, STIP knockdown did not result in the dephosphorylation of p-ERK1/2, suggesting the dependence of STIP on protein phosphatase in the regulation of ERK1/2. Among those protein phosphatase inhibited by Calyculin A, PP1 gamma was found to interact with STIP proven by immunofluorescence and immunoprecipitation assays. The binding of STIP with PP1 gamma may decrease the phosphatase activity of PP1 gamma, resulting in hyper-activated ERK1/2 signaling."

According to the news editors, the research concluded: "In summary, the high expression and activation effect on the ERK1/2 signaling of STIP in lymphoblastic leukemia suggest that STIP would be a potential therapy target or diagnosis marker for leukemia."
For more information on this research see: STIP Regulates ERK1/2 Signaling Pathway Involved in Interaction with PP1 gamma in Lymphoblastic Leukemia. *Current Molecular Medicine*, 2016;16(8):767-775. *Current Molecular Medicine* can be contacted at: Bentham Science Publ Ltd, Executive Ste Y-2, PO Box 7917, Saif Zone, 1200 Br Sharjah, U Arab Emirates. Researchers from Central South University Report Details of New Studies and Findings in the Area of Hypertension (Renin-angiotensin-aldosterone system gene polymorphisms in gestational hypertension and preeclampsia: A case-control ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Cardiovascular Diseases and Conditions - Hypertension is now available. According to news originating from Changsha, People's Republic of China, by NewsRx correspondents, research stated, "Pregnancy-induced hypertension (PIH, including preeclampsia [PE] and gestational hypertension [GH]) and cardiovascular diseases (CVDs) have some metabolic changes and risk factors in common. Many studies have reported associations between single nucleotide polymorphisms (SNPs) of renin-angiotensin-aldosterone system (RAAS) genes and CVDs (particularly hypertension), and their findings have provided candidate SNPs for research on genetic correlates of PIH."

Our news journalists obtained a quote from the research from Central South University, "We explored the association between hypertension-related RAAS SNPs and PIH in a Chinese population. A total of 130 cases with PE, 67 cases with GH, and 316 controls were recruited. Six candidate SNPs of the RAAS system were selected. Multiple logistic regression analysis adjusting for maternal age, fetal sex, and gestational diabetes mellitus showed significant associations between angiotensinogen (AGT) rs3789678 T/C and GH (p = 0.0088) and between angiotensin II receptor type 1 (AGTR1) rs275645 G/A and PE (p = 0.0082). The study population was further stratified by maternal age (< 30 and >= 30 years), and stratified and crossover analyses were conducted to determine genetic associations in different age groups."

According to the news editors, the research concluded: "Our findings suggest that the impacts of different SNPs might be affected by maternal age; however, the effect of this potential gene-age interaction on PIH needs further exploration."

Researchers from Chang Gung Memorial Hospital Describe Findings in Colon Cancer (Antidepressants and colorectal cancer: A population-based nested case-control study)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Oncology - Colon Cancer have been published. According to news originating from Chiayi, Taiwan, by NewsRx correspondents, research stated, "Experimental evidence indicates that serotonin is associated with both proliferative and procarcinogenic effects on colorectal tumors. The present study aims to investigate the associations between antidepressant use and colorectal cancer in an epidemiological sample."

Financial supporters for this research include Tsaotun Psychiatry Center, Chiayi Chang Gung Memorial Hospital.

Our news journalists obtained a quote from the research from Chang Gung Memorial Hospital, "We conducted a population-based case-control study utilizing Taiwan's National Health Insurance Research Database (NHIRD). We identified 49,342 cases with colorectal cancer and 240,985 controls between 1997 and 2008. We conducted conditional logistic regression analyses to assess the association between antidepressant use and colorectal cancer risk. Sensitivity analyses were conducted to assess whether genotoxic antidepressants (i.e. antidepressants which may exert procarcinogenic effects) would increase risk for colorectal cancer. Selective serotonin reuptake inhibitors (adjusted OR=1.00, 95% CI=0.94-1.06), tricyclic antidepressants, serotonin-norepinephrine reuptake inhibitors, and serotonin antagonist and reuptake inhibitors were not associated with increased incidence of colorectal cancer. Monoamine oxidase inhibitors were, however, associated with an increased incidence of colorectal cancer (adjusted OR=1.22, 95% CI=1.06-1.41). Higher cumulative dose of mirtazapine was associated with a decreased incidence of colorectal cancer (adjusted OR=0.39, 95% CI=0.17-0.90). A small sample size of individuals who received mirtazapine, however, precludes definitive conclusions regarding protective effects with mirtazapine. Limitations: We could not discern the effects of obesity and other risk factors for colorectal cancer from the NHIRD. Contemporary first-line antidepressants (i.e. SSRI, SNRI), as well as older agents (i.e."

According to the news editors, the research concluded: "TCA), are not associated with increased incidence of colorectal cancer."

For more information on this research see: Antidepressants and colorectal cancer: A

**Researchers from Chang Gung University Describe Findings in Obesity (Effectiveness of community-based exercise intervention programme in obese adults with metabolic syndrome)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Nutritional and Metabolic Diseases and Conditions - Obesity is the subject of a report. According to news reporting originating in Taoyuan, Taiwan, by NewsRx journalists, research stated, "Aims and objectives. The objective of this study was to change the anthropometric, clinical, biochemical indicators and the rate of metabolic syndrome among obese adults in community."

The news reporters obtained a quote from the research from Chang Gung University, "Obesity is an indicator of metabolic syndrome and cardiometabolic diseases. Obesity increases national health care expenditure in Taiwan. The high prevalence of obesity is not only a public health issue but also an economic problem. Changes in lifestyle can help to prevent metabolic syndrome for individuals with obesity. A randomised controlled trial was applied. In this randomised controlled trial by location, 136 metabolically abnormal obese individuals were included. The related indicators with metabolic syndrome were measured at baseline and after six months. The experimental group participated in a six-month community-based programme including provided exercise environments, exercise skills and volunteers’ reminding. The control group was only provided environment and skills. One hundred and thirty-one participants completed this trial. In comparison with the baseline, the intervention group showed a significant increase in high-density lipoprotein cholesterol (2.34 mg/dl), and decrease in body weight (1.09 kg), waist circumference (3.63 cm), systolic blood pressure (10.52 mmHg), diastolic blood pressure (5.21 mmHg), fasting blood glucose (5.84 mg/dl) and body mass index (0.74 kg/m(2)). In the control group, significant decrease in body mass index and waist circumference were discovered. Compared to the changes between the two groups, the results showed there were significant differences in waist circumference, systolic blood pressure, diastolic blood pressure and high-density lipoprotein cholesterol. The community-based
intervention could help to improve high-density lipoprotein cholesterol, reduce body weight, body mass index, waist circumference, blood pressure and fasting blood glucose in metabolically abnormal obese. Relevance to clinical practice. This community-based programme helped metabolically abnormal obese individuals become metabolically healthy. In the future, community nurses will work with village heads and volunteers. They can encourage residents in the communities to have healthy lifestyle.”

According to the news reporters, the research concluded: "As a result, the goal of this programme will be successfully achieved with less time and effort."

Our news correspondents report that additional information may be obtained by contacting S.H. Chang, Chang Gung Univ Sci & Technol, Dept. of Nursing, Taoyuan 33303, Taiwan. Additional authors for this research include M.C. Chen, N.H. Chien and H.F. Lin.

Liver Diseases and Conditions - Hepatitis B Virus

Researchers from Chang Gung University Report Details of New Studies and Findings in the Area of Hepatitis B Virus (Hepatitis B viremia in completely immunized individuals negative for anti-hepatitis B core antibody)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Liver Diseases and Conditions - Hepatitis B Virus are presented in a new report. According to news originating from Taoyuan, Taiwan, by NewsRx correspondents, research stated, "The presence of anti-hepatitis B virus (HBV) core antibody (anti-HBc) is considered a sensitive lifetime marker of HBV infection. Here, we examined this dogma by investigating the prevalence of hepatitis B viremia in anti-HBc negative complete vaccines in Taiwan."

Our news journalists obtained a quote from the research from Chang Gung University, "A total of 795 participants (1.7-20.0 years old) had completed HBV vaccination in infancy and were anti-HBc negative. Serum samples were available for 460 individuals with isolated anti-HBV surface antibodies (anti-HBs) (HBsAg-negative and anti-HBc negative) and for 245 individuals who tested negative for all 3 markers (triple seronegative). All samples were
submitted for polymerase chain reaction (PCR) targeting both the preS/S and X/pre-C gene regions. Of the 460 participants with isolated anti-HBs, 26 (5.65%) were positive for HBV by 2-target PCR. Of the 245 triple seronegative samples, 12 (4.90%) were positive for HBV DNA. In the former group, the prevalence of viremia was significantly higher in individuals aged 6 to 10 years than in all other ages combined (11.82% vs 3.7%, P=0.001). The anti-HBs titers were significantly lower in participants 6 to 10 years old than in all other ages combined (72.06 vs 99.64mIU/mL, P=0.038). In total, 7 (0.99%) subjects had quantifiable HBV DNA levels (280-18,820IU/mL). Sequence analysis of the S gene revealed vaccine escape like mutations."

According to the news editors, the research concluded: "Hepatitis B viremia can occur in completely vaccinated individuals who are negative for anti-HBc."

For more information on this research see: Hepatitis B viremia in completely immunized individuals negative for anti-hepatitis B core antibody. Medicine, 2016:95(49):628-633. Medicine can be contacted at: Lippincott Williams & Wilkins, Two Commerce Sq, 2001 Market St, Philadelphia, PA 19103, USA. (Elsevier - www.elsevier.com; Medicine - www.journals.elsevier.com/medicine/)

The news correspondents report that additional information may be obtained from C.T. Yeh, Chang Gung University, Mol Med Res Center, Taoyuan, Taiwan. Additional authors for this research include T.Y. Lin, K.H. Liang, W.R. Lin and C.T. Yeh.

Angiology

Researchers from Chang Gung University Report on Findings in Angiology (Effect of dehydration on the development of collaterals in acute middle cerebral artery occlusion)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Angiology have been presented. According to news reporting from Taoyuan, Taiwan, by NewsRx journalists, research stated, "Recent large series studies have demonstrated that dehydration is common amongst stroke subjects and is associated with poor outcome. However, the effects of hydration status on the development of collaterals have never been discussed."

Funder for this research include Chang Gung Medical Research Fund, Chang Gung Memorial Hospital, Chiayi, Taiwan.

The news correspondents obtained a quote from the research from Chang Gung University, "In this study, the hypothesis that hydration status is an important factor for developing collaterals after acute middle cerebral artery (MCA) infarction was tested. Eighty-seven patients with acute infarction due to occlusion of the MCA were enrolled. Two collateral markers, posterior cerebral artery (PCA) laterality and fluid-attenuated inversion recovery hyperintense vessels (HVs) were assessed from magnetic resonance imaging. Dehydration status was defined by a nitrogen to creatinine ratio of 15. The associations between
dehydration status and the development of collaterals were estimated. Sixty-one of 87 patients (70.1%) were identified as dehydrated. The development of PCA laterality and HVs shows a significant difference between dehydrated and euhydrated patients. A serum nitrogen to creatinine ratio <15, diastolic blood pressure and the presence of a dense MCA on computed tomography were significantly associated with the development of PCA laterality. A serum nitrogen to creatinine ratio <15, the initial National Institutes of Health Stroke Scale score, the presence of a dense MCA and calcifications of the internal carotid artery on computed tomography were significantly associated with the development of HVs. Dehydration remained an independent negative predictor for the development of PCA laterality and HVs in the multivariate analysis. Hydration status is associated with the development of collateral flow after acute MCA occlusion."

According to the news reporters, the research concluded: "This preliminary study provides an imaging clue that hydration status and early hydration therapy could be important for acute stroke management."

Our news journalists report that additional information may be obtained by contacting S.W. Chang, Dept. of Diagnostic Radiology, Chang Gung Memorial Hospital, Chiayi, College of Medicine, Chang Gung University, Taoyuan, Taiwan. Additional authors for this research include Y.C. Huang, L.C. Lin, J.T. Yang, H.H. Weng, Y.H. Tsai and T.H Lee.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1111/ene.12841. This DOI is a link to an online electronic document that is either free or for purchase.

Keywords for this news article include: Asia, Taiwan, Taoyuan, Angiology, Imaging Technology, Computed Tomography, Middle Cerebral Artery Infarction, Central Nervous System Diseases and Conditions.

Nutritional and Metabolic Diseases and Conditions –…

Researchers from Chang Gung University Report on Findings in Type 2 Diabetes (Impact of baseline body mass index status on glucose lowering and weight change during sitagliptin treatment for type 2 diabetics)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Nutritional and Metabolic Diseases and Conditions - Type 2 Diabetes. According to news originating from Kaohsiung, Taiwan, by NewsRx correspondents, research stated, "This study was designed to evaluate the efficacy of sitagliptin in Taiwanese diabetic subjects with different baseline BMI status. This was a single-center, hospital-based, retrospective chart review in subjects (n = 1874) with type 2 diabetes who received sitagliptin."

Our news journalists obtained a quote from the research from Chang Gung University, "Subjects were classified into subgroups depending upon their baseline BMI by
Taiwan national weight classification: normal (BMI < 24 kg/m(2)) (n = 504), overweight (BMI: 24-27 kg/m(2)) (n = 615), and obese (BMI >= 27 kg/m(2)) (n = 755). Changes in HbA1c and weight were evaluated over a 12month treatment period. For all three groups, the HbA1c levels declined over the first three months by about 8%, and subsequently plateaued for the next nine months. Obese subjects were slower in reducing HbA1c compared with normal and overweight subjects (P < 0.05), but at nine months the reduction was similar across groups. Mean body weight increased over the first nine months of sitagliptin therapy in subjects with normal BMI (57.12-58.30 kg), but there was no change in mean body weight in the overweight group. After three months the obese groups had significantly greater loss in body weight compared with the normal group. Baseline BMI status may influence the reduction of HbA1c levels within the first six months of sitagliptin therapy and affect weight change after three months."

According to the news editors, the research concluded: "Being obese was associated with an initial lag in HbA1c reduction and greater weight loss compared with normal and overweight subjects."

For more information on this research see: Impact of baseline body mass index status on glucose lowering and weight change during sitagliptin treatment for type 2 diabetics. Diabetes Research and Clinical Practice, 2016;120():8-14. Diabetes Research and Clinical Practice can be contacted at: Elsevier Ireland Ltd, Elsevier House, Brookvale Plaza, East Park Shannon, Co, Clare, 00000, Ireland. (Elsevier - www.elsevier.com; Diabetes Research and Clinical Practice - www.journals.elsevier.com/diabetes-research-and-clinical-practice/)

The news correspondents report that additional information may be obtained from J.F. Chen, Chang Gung University, Coll Med, 123 Ta Pei Rd, Kaohsiung, Taiwan. Additional authors for this research include C.M. Chang, M.C. Kuo, S.C. Tung, C.F. Tsao and C.J. Tsai.

Researchers from Charite University Hospital and School of Medicine Report on Findings in Hypercholesterolemia (Clinical characterization and mutation spectrum of German patients with familial hypercholesterolemia)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Nutritional and Metabolic Diseases and Conditions - Hypercholesterolemia are discussed in a new report. According to news reporting out of Berlin, Germany, by NewsRx editors, research stated, "Autosomal-dominant familial hypercholesterolemia (FH) is characterized by elevated plasma levels of low-density lipoprotein cholesterol (LDL-C) and a dramatically increased risk to develop cardiovascular disease (CVD). Mutations in three major genes have been associated with FH: the LDL receptor gene (LDLR),
the apolipoprotein B gene (APOB), and the proprotein convertase subtilisin/kexin 9 gene (PCSK9)."

Our news journalists obtained a quote from the research from the Charite University Hospital and School of Medicine, "Here we investigated the frequency and the spectrum of FH causing mutations in Germany. We screened 206 hypercholesterolemic patients, of whom 192 were apparently unrelated, for mutations in the coding region of the genes LDLR, PCSK9 and the APOB [c. 10580G > A (p. Arg3527Gln)]. We also categorized the patients according to the Dutch Lipid Clinic Network Criteria (DLCNC) in order to allow a comparison between the mutations identified and the clinical phenotypes observed. Including data from previous studies on German FH patients enabled us to analyse data from 479 individuals. Ninety-eight FH causing variants were found in 92 patients (nine in related patients and 6 patients with two variants and likely two affected alleles), of which 90 were located in the LDLR gene and eight mutations were identified in the APOB gene (c. 10580G > A). No mutation was found in the PCSK9 gene. While 48 of the LDLR mutations were previously described as disease causing, we found 9 new LDLR variants which were rated as 'pathogenic' or 'likely pathogenic' based on the predicted effect on the corresponding protein. The proportions of different types of LDLR mutations and their localization within the gene was similar in the group of patients screened for mutations here and in the combined analysis of 479 patients (current study/cases from the literature) and also to other studies on the LDLR mutation spectrum, with about half of the variants being of the missense type and clustering of mutations in exons 4, 5 and 9. The mutation detection rate in the 35 definite and 45 probable FH patients (according to DLCNC) was 77.1% and 68.9%, respectively. The data show a similar discriminatory power between the DLCNC score (AUC = 0.789 (95% CI 0.721-0.857)) and baseline LDL-C levels (AUC = 0.799 (95% CI = 0.732-0.866)))."

According to the news editors, the research concluded: "This study further substantiates the mutation spectrum for FH in German patients and confirms the clinical and genetic heterogeneity of the disease."

For more information on this research see: Clinical characterization and mutation spectrum of German patients with familial hypercholesterolemia. _Atherosclerosis_, 2016;253 ():88-93. _Atherosclerosis_ can be contacted at: Elsevier Ireland Ltd, Elsevier House, Brookvale Plaza, East Park Shannon, Co, Clare, 00000, Ireland. Researchers from Charles University Report Findings in Cardiovascular Research (Obstruction after alcohol septal ablation is associated with cardiovascular mortality events)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Cardiovascular Research. According to news reporting out of Prague, Czech Republic, by NewsRx editors, research stated, "Left ventricular outflow tract obstruction (>= 30 mm Hg at rest; LVOTO) is considered a possible risk of long-term outcomes in patients with hypertrophic cardiomyopathy (HCM). However, the influence of LVOTO on the occurrence of cardiovascular mortality events in patients after alcohol septal ablation (ASA) for obstructive HCM remains unresolved."

Our news journalists obtained a quote from the research from Charles University, "We compared the outcomes of patients treated with ASA with residual LVOTO < 30 mm Hg with those with residual LVOTO >= 30 mm Hg at the first postdischarge check-up (1-6 months after the procedure). A total of 270 patients (60 +/- 12 years, median follow-up 5.1 years; 95% CI 4.5 to 5.9 years) treated with a single ASA were included; 208 (77%) and 62 (23%) patients had post-ASA LVOTO < 30 and >= 30 mm Hg at the first postdischarge clinical check-up, respectively (LVOTO 13 +/- 6 vs 50 +/- 27 mm Hg; p<0.01). Freedom from cardiovascular mortality events at 1, 5 and 10 years were 99% (95% CI 96% to 100%) vs 94% (95% CI 85% to 98%), 95% (95% CI 89% to 97%) vs 80% (95% CI 66% to 89%) and 82% (95% CI 69% to 89%) vs 72% (95% CI 55% to 84%) (log-rank test, p<0.01), respectively. In multivariable analysis adjusted for age at ASA, sex, baseline LVOTO and baseline septum thickness, the independent predictors of cardiovascular mortality events were early postdischarge LVOTO >= 30 mm Hg (HR 2.95, 95% CI 1.26 to 6.91; p=0.01) and baseline septum thickness (HR 1.07, 95% CI 1.01 to 1.13; p=0.02)."

According to the news editors, the research concluded: "After ASA for obstructive HCM, LVOTO >= 30 mm Hg at the first postdischarge clinical check-up is associated with significantly higher occurrence of subsequent cardiovascular mortality events."

For more information on this research see: Obstruction after alcohol septal ablation is associated with cardiovascular mortality events. *Heart, 2016;102(22):1793-1796. Researchers from Chengdu University Report New Studies and Findings in the Area of Breast Cancer (Regulation of epithelial-mesenchymal transition through microRNAs: clinical and biological significance of microRNAs in breast cancer)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Oncology - Breast Cancer are discussed in a new report. According to news reporting from Chengdu, People's Republic of China, by NewsRx journalists, research stated, "Breast cancer is a malignant disease to treat among female worldwide due to its high capability to metastasize and mutate. Epithelial-mesenchymal transition is one of the essential processes involved in the metastatic capacity of breast cancer."

Financial support for this research came from National Natural Science Foundation of China.

The news correspondents obtained a quote from the research from Chengdu University, "In the recent time, the studies demonstrate that microRNAs, a kind of small non-coding RNA molecules, could be served as negative regulators in breast cancer, regulating cell cycle, drug resistance, and the process of metastasis in cancer development. With the assistance of microRNA profiling, the study concentrating on the regulatory function of miRNAs in breast cancer could be investigated more effectively and efficiently. More recent studies demonstrate that miRNAs have an important role to play in the EMT process of breast cancer to modulate metastasis."

According to the news reporters, the research concluded: "This small essay is on the purpose of demonstrating the significance and detection of miRNAs in breast cancer EMT process as oncogenes and tumor suppress genes through miRNA profiling according to the reports mainly in the recent 5 years, providing the evidence of efficient target therapy and effective pro-diagnosis focusing on miRNAs expression of breast cancer patients."

For more information on this research see: Regulation of epithelial-mesenchymal transition through microRNAs: clinical and biological significance of microRNAs in breast cancer. Tumor Biology, 2016;37(11):14463-14477. Tumor Biology can be contacted at: Springer, Van Godewijckstraat 30, 3311 Gz Dordrecht, Netherlands. Researchers from Children's Hospital Report Details of New Studies and Findings in the Area of Endocrine Cells (Evidence for feasibility of fetal trophoblastic cell-based noninvasive prenatal testing)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Endocrine Cells have been published. According to news originating from Houston, Texas, by NewsRx correspondents, research stated, "The goal was to develop methods for detection of chromosomal and subchromosomal abnormalities in fetal cells in the mother's circulation at 10-16 weeks' gestation using analysis by array comparative genomic hybridization (CGH) and/or next-generation sequencing (NGS). Nucleated cells from 30 mL of blood collected at 10-16 weeks' gestation were separated from red cells by density fractionation and then immunostained to identify cytokeratin positive and CD45 negative trophoblasts."

Our news journalists obtained a quote from the research from Children's Hospital, "Individual cells were picked and subjected to whole genome amplification, genotyping, and analysis by array CGH and NGS. Fetal cells were recovered from most samples as documented by Y chromosome PCR, short tandem repeat analysis, array CGH, and NGS including over 30 normal male cells, one 47, XXY cell from an affected fetus, one trisomy 18 cell from an affected fetus, nine cells from a trisomy 21 case, three normal cells and one trisomy 13 cell from a case with confined placental mosaicism, and two chromosome 15 deletion cells from a case known by CVS to have a 2.7 Mb de novo deletion."

According to the news editors, the research concluded: "We believe that this is the first report of using array CGH and NGS whole genome sequencing to detect chromosomal abnormalities in fetal trophoblastic cells from maternal blood."

The news correspondents report that additional information may be obtained from A.L. Beaudet, Texas Childrens Hosp, Houston, TX 77030, United States. Additional authors for this research include J.C. Chow, L. U'Ren, E.A. Normand, S. Qdaisat, L. Zhao, D.M. Henke, R. Chen, C.A. Shaw, L. Jackson, Y.P. Yang, L. Vossaert, R.H.V. Needham, E.J. Chang, D. Campton, J.L. Werbin, R.C. Seubert, I.B. Van den Veyver and J Stilwell.

Researchers from Children's Research Institute Report New Studies and Findings in the Area of Sickle Cell Anemia (Substance P is increased in patients with sickle cell disease and associated with haemolysis and hydroxycarbamide use)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Hematologic Diseases and Conditions - Sickle Cell Anemia. According to news reporting originating in Milwaukee, Wisconsin, by NewsRx journalists, research stated, "Sickle cell disease (SCD) pain transitions from acute to chronic for unknown reasons. Chronic elevation of the pain neurotransmitter substance P (SP) sensitizes pain nociceptors."

Funders for this research include American Society of Hematology, Midwest Athletes Against Childhood Cancer and Blood Diseases Fund.

The news reporters obtained a quote from the research from Children's Research Institute, "We evaluated SP levels in controls and SCD patients during baseline and acute pain and investigated associations between SP and age, gender, pain history, haemolysis and hydroxycarbamide (also termed hydroxyurea) use. Plasma SP levels were measured using enzyme-linked immunosorbent assay. Independent samples t-test compared SP levels between: (i) SCD baseline and controls, and (ii) SCD baseline and acute pain. Multivariate linear regression determined associations between SP and age, gender, pain history and hydroxycarbamide use. Spearman correlation determined an association between SP and haemolysis. We enrolled 35 African American controls, 25 SCD baseline and 12 SCD pain patients. SCD patients were 7-19 years old. Mean +/- standard deviation SP level (pg/ml) in SCD baseline was higher than controls (324 +/- 116 vs. 229 +/- 76, P=00009). SP in SCD pain was higher than baseline (781 +/- 434 vs. 324 +/- 116, P=0004). Haemolysis correlated with increased SP: Hb (r=-07, P=00002), reticulocyte count (r=061, P=00016), bilirubin (r=068, P=00216), lactate dehydrogenase (r=062, P=00332), aspartate aminotransferase (r=068, P=0003). Patients taking hydroxycarbamide had increased SP (r=292, P=0007)."

According to the news reporters, the research concluded: "SP could be a mediator of or marker for pain sensitization in SCD and a biomarker and/or target for novel pain treatment."

Our news correspondents report that additional information may be obtained by contacting A.M. Brandow, Children's Hospital of Wisconsin, Childrens Res Inst, Milwaukee, WI, United States. Additional authors for this research include N.J. Wandersee, M. Dasgupta, R.G. Hoffmann, C.A. Hillery, C.L. Stucky and J.A. Panepinto.

Researchers from China Medical University and Hospital Detail New Studies and Findings in the Area of Multiple Myeloma (Expression and significance of miR-21 in multiple myeloma patients)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Oncology - Multiple Myeloma. According to news originating from Liaoning, People's Republic of China, by NewsRx correspondents, research stated, "The aim of the present study is to examine the expression level of peripheral mir-21 in multiple myeloma (MM) patients and to determine its clinical significance. MM patients (30), monoclonal gammopathy of undetermined significance (MGUS) patients (14), and normal controls (20) were recruited to determine the serum level of b2-MG, IgA and IgM, IgG, I, k, TP, ALB, Hb, LDH, and Ca(2+)."

Our news journalists obtained a quote from the research from China Medical University and Hospital, "Gene expression of mir-21 was quantified by SYBR green real-time fluorescent quantitative PCR. We found that the expression level of serum mir-21 in the MM group was significantly higher than the MGUS group and the NC group (p <0.01). According to the ISS installment, the level of mir-21, IgG, k, and ALB in the MM group in stage I differed from that in stages II and III. The level of IgA, b2-MG in stage III was higher as compared with stage I and II (p <0.05 and p<0.01).The levels of mir-21, k, (k+l), IgG, (IgG + IgA + IgM), and b2-MG in MM patients were positively correlated with ALB (p <0.01). Based on the results, miR-21 plays an important role as an oncogene."

According to the news editors, the research concluded: "Mir-21 may be important in the occurrence, development, and disease prognosis of MM."

For more information on this research see: Expression and significance of miR-21 in multiple myeloma patients. *Genetics and Molecular Research [electronic Resource],* 2016;15 (1):.

The news correspondents report that additional information may be obtained from J.H. Wang, The Laboratory Medicine of First Affiliated Hospital of China Medical University, Shenyang, Liaoning, People's Republic of China. Additional authors for this research include W.W. Zhou, B.X. Researchers from China Medical University and Hospital Report Findings in Oral Cancer (Dithiothreitol enhanced arsenic-trioxide-induced cell apoptosis in cultured oral cancer cells via mitochondrial dysfunction and endoplasmic reticulum stress)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Oncology - Oral Cancer. According to news reporting originating in Taichung, Taiwan, by NewsRx journalists, research stated, "Arsenic is naturally occurring toxic metalloid and drinking As O containing water are recognized to be related to increased risk of neurotoxicity, liver injury, blackfoot disease, hypertension, and cancer. On the contrary, As O has been an ancient drug used in traditional Chinese medicine with substantial anticancer activities, especially in the treatment of acute promyelocytic leukemia as well as chronic wound healing."

Financial supporters for this research include National Science Council, Ministry of Science and Technology (named from National Science Council), Terry Fox Cancer Research Foundation, Taiwan Ministry of Health and Welfare Clinical Trial and Research Center of Excellence.

The news reporters obtained a quote from the research from China Medical University and Hospital, "However, the cytotoxicity and detail mechanisms of As O action in solid cancer cells, such as oral cancer cells, are largely unknown. In this study, we have primarily cultured four pairs of tumor and nontumor cells from the oral cancer patients and treated the cells with As O alone or combined with dithiothreitol (DTT). The results showed that 0.5 mM As O plus 20 mM DTT caused a significant cell death of oral cancer cells but not the nontumor cells. Also As O plus DTT upregulated Bax and Bak, downregulated Bcl-2 and p53, caused a loss of mitochondria membrane potential in oral cancer cells. On the other way, As O also triggered endoplasmic reticulum stress and increased the levels of glucose-regulated protein 78, calpain 1 and 2. Our results suggest that DTT could synergistically enhance the effects of As O on killing oral cancer cells while nontoxic to the nontumor cells."

According to the news reporters, the research concluded: "The combination is promising for clinical practice in oral cancer therapy and worth further investigations. ? 2015 Wiley Periodicals, Inc. Environ Toxicol 32:17-27.,"

Our news correspondents report that additional information may be obtained by contacting C.W. Tsai, Terry Fox Cancer Research Laboratory, China Medical University Hospital, Taichung, Taiwan. Additional authors for this research include M.D. Yang, T.C. Hsia, W.S. Chang, C.M. Hsu, Y.H. Hsieh, J.G. Chung and D.T Bau.

Researchers from China Pharmaceutical University Discuss Findings in Steatosis (Long-term Stress with Hyperglucocorticoidemia-induced Hepatic Steatosis with VLDL Overproduction Is Dependent on both 5-HT2 Receptor and 5-HT Synthesis in Liver)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Steatosis is the subject of a report. According to news reporting originating in Nanjing, People's Republic of China, by NewsRx journalists, research stated, "Hepatic triglycerides production and adipose lipolysis are pivotal for long-term stress (LTS) or hyperglucocorticoidemia-induced insulin resistance. 5-hydroxytryptamine (5-HT) has been demonstrated to induce hepatic lipid metabolic abnormality by activating mammalian target of rapamycin (mTOR). In present study, we explored whether 5-HT is involved in LTS effects in liver using restraint stress-exposed rats and cultured primary rat hepatocytes and HepG2 cells."

The news reporters obtained a quote from the research from China Pharmaceutical University, "LTS with hyperglucocorticoidemia induced hepatic 5-HT synthetic increase with tryptophan hydroxylase 1 (Tph1) up-regulation, and 5-HT2 receptor (5-HT2R, including 5-HT2A, 2B receptor) up-regulation in liver and visceral adipose, as well as hepatic mTOR activation with triglycerides and VLDL overproduction with steatosis, and visceral adipose lipolytic increase with high blood free fatty acids (FFAs) level. 5-HT exposure exhibited LTS-like effects in both tissues, and both LTS and 5-HT effects could be abolished significantly by blocking 5-HT2R. In HepG2 cells dexamethasone or palmitate-induced mTOR activation with triglycerides and VLDL overproduction were accompanied by up-regulations of 5-HT synthesis and 5-HT2R, which were significantly abolished by gene silencing Tph1 or 5-HT2R and were almost fully abolished by co-silencing of both, especially on VLDL overproduction. Chemical inhibition of Tph1 or/and 5-HT2R in both hepatocytes exhibited similar abolishment with genetic inhibition on dexamethasone-induced effects. 5-HT-stimulated effects in both hepatocytes were fully abolished by blocking 5-HT2R, while 5-HT itself also up-regulated 5-HT2R."

According to the news reporters, the research concluded: "Up-regulated hepatic 5-HT synthesis and 5-HT2R induced by both glucocorticoid and FFAs are crucial for LTS-induced hepatic steatosis with VLDL overproduction, while 5-HT by acting on 5-HT2R mediates mTOR activation in liver."

Our news correspondents report that additional information may be obtained by contacting J. Fu, 1 Postgraduates of China Pharmaceutical University, Nanjing, People's Republic of China. Additional authors for this research include S. Ma, X. Li, S. An, T. Li, K.
Researchers from Chinese Academy of Fishery Sciences Describe Findings in Clinical Trials and Studies (Comparative Study on Physical-Chemical and Biological Characteristics of Grass Carp Reovirus From Different Genotypes)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Clinical Research - Clinical Trials and Studies is now available. According to news reporting originating from Guangdong, People's Republic of China, by NewsRx correspondents, research stated, "Grass carp reovirus (GCRV) was first isolated in 1983. In China, the virus caused severe hemorrhagic disease with significant losses of fingerling and yearling grass carp, Cyenopharyngodon idellus."

Our news editors obtained a quote from the research from the Chinese Academy of Fishery Sciences, "Clade analysis of the different GCRV isolates from China indicates there are three distinct branches, which represent genotypes I, II, and III. However, little is known about the physical-chemical and biological characteristics of viruses from these three genotypes. In this study, the morphologic characteristics of JX-0901 (genotype I), HZ08 (genotype II), and Hubei grass carp disease reovirus (genotype III) were determined using electron microscopy which revealed morphological similarities but viral particles of the isolates arrayed in different ways. A comparison of selected viruses was performed for physical and chemical properties, including stability under different pH conditions, treatment with ether and trypsin, and repeated freeze-thaw cycles. Three isolates showed similar resistance to treatment with ether or trypsin and were stable between pH 3 and pH 10. The viruses exhibited different proliferation curves in the Grass carp swimming bladder cell. No postinfection mortalities or histological lesions were observed in infected rare minnow. Furthermore, cross-protection assays revealed low cross protection between different genotype viruses."

According to the news editors, the research concluded: "This study contributes to the body of knowledge concerning disease control and vaccine development for grass carp hemorrhagic disease."

The news editors report that additional information may be obtained by contacting
Researchers from Chinese Academy of Medical Sciences Detail Findings in Human Immunology (Association study of rs924080 and rs11209032 polymorphisms of IL23R-IL12RB2 in a Northern Chinese Han population with Behcet's disease)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Immunology - Human Immunology. According to news reporting originating in Beijing, People's Republic of China, by NewsRx journalists, research stated, "Two genome-wide association studies (GWAS) have identified the IL-23 receptor- IL-12 receptor beta 2 (1L23R-IL12RB2) as the susceptibility genetic region in Turkish and Japanese population with Behcet's disease (BD). We investigated the association of this region with BD in a Northern Chinese Han population."

The news reporters obtained a quote from the research from the Chinese Academy of Medical Sciences, "A total of 407 patients with BD and 421 healthy controls were genotyped for single nucleotide polymorphisms (SNPs) rs924080 and rs11209032 using the Sequenom MassArray system. Statistically significant associations with BD were detected at two SNPs namely, rs924080 and rs11209032, both, by allele analysis (OR = 1.58, 95% CI = 1.25-2.00, P-c = 2.52 x 10(-4), and OR =1.45, 95% CI = 1.19-1.76, P-c = 3.46 x 10(-4), respectively), and genotype analysis (P-c = 1.22 x 10(-3) and P-c = 1.77 x 10(-3), respectively). Significant differences were observed in the genotype frequency distribution for these SNPs under the additive, dominant and recessive models (all P-c < 0.05). The haplotypes (AT and GC) formed by the two SNPs were associated with BD (all permutation P< 0.05). A meta-analysis also appeared to support the association of the two SNPs with BD."

According to the news reporters, the research concluded: "SNPs (rs924080 and rs11209032) of the IL23R-IL12RB2 region were found to be associated with BD in a Northern Chinese Han population."

For more information on this research see: Association study of rs924080 and rs11209032 polymorphisms of IL23R-IL12RB2 in a Northern Chinese Han population with Behcet's disease. Human Immunology, 2016;77(12):1284-1290. Human Immunology can be contacted at: Elsevier Science Inc, 360 Park Ave South, New York, NY 10010-1710, USA. (Elsevier - www.elsevier.com; Human Immunology - www.journals.elsevier.com/human-immunology/)

Our news correspondents report that additional information may be obtained by contacting F.C. Zhang, Chinese Academy Med Sci, Beijing 100730, People's Republic of China. Additional authors for this research include J.J. Xu, Z.Y. Wu, F. Sun, H. Chen, W.J. Zheng, S.
Cardiovascular Diseases and Conditions - Aneurysm

Researchers from Chinese Academy of Medical Sciences Detail New Studies and Findings in the Area of Aneurysm (Endovascular stenting for extracranial carotid artery aneurysms Experiences and mid-term results)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Cardiovascular Diseases and Conditions - Aneurysm are presented in a new report. According to news reporting from Beijing, People's Republic of China, by NewsRx journalists, research stated, "The aim of this study was to investigate the safety and effectiveness of endovascular stenting for extracranial carotid artery aneurysms (ECAAs) and evaluate the mid-term outcomes. Twelve consecutive symptomatic patients (mean age 43.8 +/- 14.9 years; 8 men) with ECAAs who were treated with endovascular stenting between 1997 and 2015 were retrospectively analyzed."

The news correspondents obtained a quote from the research from the Chinese Academy of Medical Sciences, "Clinical follow-up data including symptoms and neurological events were obtained from outpatient records. Imaging follow-up with duplex ultrasound and/or computed tomographic angiography (CTA) was performed to examine the aneurysm obliteration and patency of the stents at 3, 6, 12 months and yearly thereafter. A total of 5 true aneurysms and 7 pseudoaneurysms were included in our series. Neurological symptoms (n = 5, 41.7%) and a pulsatile neck mass (n = 5, 41.7%) were the most common presenting symptoms. Endovascular stenting procedures were technically successful in all cases; 3 patients received bare stents, and 9 patients received covered stents. No perioperative neurologic or cardiopulmonary complications occurred. Over a period of follow-ups (mean 21.8 +/- 25.1 months), all patients were alive and free from neurological or other adverse events. All aneurysms were completely excluded except for 1 patient who was exposed to a residual medium leaking into the aneurysm sac. No reintervention was performed in this specific patient because aneurysm growth or significant clinical symptoms did not occur. Recurrent restenosis assessed by CTA imaging at 12 months occurred in 1 (8.3%) patient in our series. Target lesion revascularization for this hemodynamic restenosis was treated with placement of an additional stent. In our series, endovascular stenting for ECAAs was found to be safe, effective, and proved to have promising mid-term results."

According to the news reporters, the research concluded: "Although long-term results need to be further explored, advantages including less procedure-related complications and a shorter recovery time make endovascular stenting an attractive option for ECAAs, especially for the patients who are unfit for traditional open surgery."

For more information on this research see: Endovascular stenting for extracranial carotid artery aneurysms Experiences and mid-term results. Medicine, 2016;95(46):397-403. Medicine can be contacted at: Lippincott Williams & Wilkins, Two Commerce Sq, 2001 Market St, Philadelphia, PA 19103, USA. (Elsevier - www elsevier com; Medicine -
Researchers from Chinese Academy of Medical Sciences Report Details of New Studies and Findings in the Area of Non-Small Cell Lung Cancer (The Efficacy and Safety of Icotinib in Patients with Advanced Non-Small Cell Lung Cancer Previously ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Oncology - Non-Small Cell Lung Cancer. According to news reporting originating from Beijing, People's Republic of China, by NewsRx correspondents, research stated, "Icotinib is a small molecule targeting epidermal growth factor receptor tyrosine kinase, which shows non-inferior efficacy and better safety comparing to gefitinib in previous phase III trial. The present study was designed to further evaluate the efficacy and safety of icotinib in patients with advanced non-small-cell lung cancer (NSCLC) previously treated with chemotherapy."

Our news editors obtained a quote from the research from the Chinese Academy of Medical Sciences, "Patients with NSCLC progressing after one or two lines of chemotherapy were enrolled to receive oral icotinib (125 mg tablet, three times per day). The primary endpoint was progression-free survival. The secondary endpoints included overall survival, objective response rate, time to progression, quality of life and safety. From March 16, 2010 to October 9, 2011, 128 patients from 15 centers nationwide were enrolled, in which 124 patients were available for efficacy evaluation and 127 patients were evaluable for safety. The median progression-free survival and time to progression were 5.0 months (95% CI 2.9-6.6 m) and 5.4 months (95% CI 3.1-7.9 m), respectively. The objective response rate and disease control rate were 25.8% and 67.7% respectively. Median overall survival exceeded 17.6 months (95% CI 14.2 m-NA) according to censored data. Further follow-up of overall survival is ongoing. The most frequent treatment-related adverse events were rash (26%, 33/127), diarrhea (12.6%, 16/127) and elevation of transaminase (15.7%, 20/127)."

According to the news editors, the research concluded: "In general, this study showed similar efficacy and numerically better safety when compared with that in ICOGEN trial, further confirming the efficacy and safety of icotinib in treating patients with advanced NSCLC previously treated with chemotherapy."

For more information on this research see: The Efficacy and Safety of Icotinib in Patients with Advanced Non-Small Cell Lung Cancer Previously Treated with Chemotherapy: A Single-Arm, Multi-Center, Prospective Study. Plos One, 2015;10(11):e0142500. (Public Library of Science - www.plos.org; Plos One - www.plosone.org)
Researchers from Chinese Peoples' Liberation Army General Hospital Detail New Studies and Findings in the Area of Thrombocytopenia (Efficacy and safety of thrombopoietin receptor agonists in patients with primary immune thrombocytopenia: A ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Hematologic Diseases and Conditions - Thrombocytopenia have been presented. According to news originating from Beijing, People's Republic of China, by NewsRx correspondents, research stated, "Immune thrombocytopenia (ITP) is an autoimmune disease characterized by increased platelet destruction and impaired platelet production. In this study, we conducted a systematic review and meta-analysis to determine the efficacy and safety of thrombopoietin receptor agonists (TPO-RA) in primary ITP patients."

Our news journalists obtained a quote from the research from Chinese Peoples' Liberation Army General Hospital, "Thirteen randomized controlled trials were included in this study, the pooled results of which demonstrated that TPO-RA significantly increased platelet response and durable response (DR) rates [risk ratio (RR): 2.77, 95% confidence interval (CI): 2.01-3.82, P = 5.9 x 10(-10); RR: 7.52, 95% CI: 3.94-14.35, P = 9.2 x 10(-10); respectively] and that TPO-RA significantly reduced the incidences of any or severe bleeding events (RR: 0.80, 95% CI: 0.67-0.95, P = 0.013; RR: 0.52, 95% CI: 0.27-0.99, P = 0.048; respectively). Moreover, our results indicated that there was a significant reduction in the proportion of patients needing rescue medications in the TPO-RA groups compared with the control groups (RR: 0.50, 95% CI: 0.42-0.59, P = 2.0 x 10(-15)) and that the rates of any or severe adverse events were similar between the TPO-RA and control regimens (RR: 1.01, 95% CI: 0.92-1.10; RR: 0.74, 95% CI: 0.54-1.01; respectively)."

According to the news editors, the research concluded: "These findings demonstrate that TPO-RA are an effective and safe second-line treatment option for primary ITP patients."

For more information on this research see: Efficacy and safety of thrombopoietin receptor agonists in patients with primary immune thrombocytopenia: A systematic review and
Researchers from Chinese University of Hong Kong Report Findings in Type 2 Diabetes (Retinal Information is Independently Associated with Cardiovascular Disease in Patients with Type 2 diabetes)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Nutritional and Metabolic Diseases and Conditions - Type 2 Diabetes have been published. According to news reporting out of Hong Kong, People's Republic of China, by NewsRx editors, research stated, "To evaluate the association between a series of retinal information and cardiovascular disease (CVD) and to evaluate whether this association is independent of traditional CVD risk factors in type 2 diabetes patients, we undertook an age-sex matched case-control study with 79 CVD cases and 150 non-CVD controls. All the participants underwent standardized physical examinations and retinal imaging."

Our news journalists obtained a quote from the research from the Chinese University of Hong Kong, "Retinal information was extracted from the retinal images using a semi-automatic computer program. Three stepwise logistic regression models were evaluated: model 1 with cardiovascular risk factors only; model 2 with retinal information only and model 3 with both cardiovascular risk factors and retinal information. The areas under the receiver operating characteristic curves (AUCs) were used to compare the performances of different models. Results showed that the AUCs were 0.692 (95%CI: 0.622-0.761) and 0.661 (95%CI: 0.588-0.735) for model 1 and model 2, respectively. In addition, model 3 had an AUC of 0.775 (95% CI: 0.716-0.834). Compared to the previous two models, the AUC of model 3 increased significantly (p <0.05 in both comparisons)."

According to the news editors, the research concluded: "Retinal information is independently associated with CVD in type 2 diabetes. Further work is needed to validate the translational value of applying retinal imaging analysis into clinical practice."

For more information on this research see: Retinal Information is Independently Associated with Cardiovascular Disease in Patients with Type 2 diabetes. Scientific Reports, 2016;6(6):19053. (Nature Publishing Group - www.nature.com; Scientific Reports -
Researchers from Christiana Care Health Systems Describe Findings in Cardiology (Impact of a Multidisciplinary Team Approach Including an Intensivist on the Outcomes of Critically Ill Patients in the Cardiac Care Unit)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Cardiology have been published. According to news reporting originating in Newark, Delaware, by NewsRx journalists, research stated, "To investigate the impact of integrating a medical intensivist into a cardiac care unit (CCU) multidisciplinary team on the outcomes of CCU patients. We conducted a retrospective cohort study of 2239 CCU admissions between July 1, 2011, and July 1, 2013, which constituted patients admitted in the 12 months before and 12 months after the introduction of intensivists into the CCU multidisciplinary team."

The news reporters obtained a quote from the research from Christiana Care Health Systems, "This team included a cardiologist, a medical intensivist, medical house staff, nurses, a pharmacist, a dietitian, and physical and respiratory therapists. The primary outcome was CCU mortality. Secondary outcomes included hospital mortality, CCU length of stay, hospital length of stay, and duration of mechanical ventilation. After the implementation of a multidisciplinary team approach, there was a significant decrease in both adjusted CCU mortality (3.5% vs 5.9%; P = .01) and hospital mortality (4.4% vs 11.1%; P< .01). A similar impact was observed on adjusted mean CCU length of stay (2.5 +/- 2.0 vs 2.9 +/- 2.0 days; P< .01), adjusted mean hospital length of stay (7.0 +/- 4.5 vs 7.5 +/- 4.5 days; P< .01), and adjusted mean ventilation duration (2.0 +/- 1.0 vs 4.3 +/- 2.5 days; P< .01)."

According to the news reporters, the research concluded: "The implementation of a multidisciplinary team approach in which an intensivist and a cardiologist comanage the critical care of CCU patients is feasible and may result in better patient outcomes."

For more information on this research see: Impact of a Multidisciplinary Team Approach Including an Intensivist on the Outcomes of Critically Ill Patients in the Cardiac Care Unit. *Mayo Clinic Proceedings*, 2016;91(12):1727-1734. *Mayo Clinic Proceedings* can be
Researchers from Chung Ang University Discuss Findings in Angina Pectoris (Percutaneous Coronary Intervention Is More Beneficial Than Optimal Medical Therapy in Elderly Patients with Angina Pectoris)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Heart Disorders and Diseases - Angina Pectoris have been presented. According to news reporting from Seoul, South Korea, by NewsRx journalists, research stated, "Data comparing the clinical benefits of medical treatment with those of percutaneous coronary intervention (PCI) in an elderly population with angina pectoris are limited. Therefore, we evaluated the efficacy of elective PCI versus optimal medical treatment (OMT) in elderly patients (between 75 and 84 years old) with angina pectoris."

Financial supporters for this research include Ministry of Health, Welfare and Family Affairs, Cardiovascular Research Center.

The news correspondents obtained a quote from the research from Chung Ang University, "One hundred seventy-seven patients with significant coronary artery stenosis were randomly assigned to either the PCI group (n=90) or the OMT group (n=87). The primary outcome was a composite of major adverse events in the 1-year follow-up period that included cardiovascular death, non-fatal myocardial infarction, coronary revascularization, and stroke. Major adverse events occurred in 5 patients (5.6%) of the PCI group and in 17 patients (19.5%) of the OMT group (p=0.015). There were no significant differences between the PCI group and the OMT group in cardiac death [hazard ratio (HR) for the PCI group 0.454; 95% confidence interval (CI) 0.041-5.019, p=0.520], myocardial infarction (HR 0.399; 95% CI 0.039-4.050, p=0.437), or stroke (HR 0.919; 95% CI 0.057-14.709, p=0.952). However, the PCI group showed a significant preventive effect of the composite of major adverse events (HR 0.288; 95% CI 0.106-0.785, p=0.015) and against the need for coronary revascularization (HR 0.157; 95% CI 0.035-0.703, p=0.016)."

According to the news reporters, the research concluded: "Elective PCI reduced major adverse events and was found to be an effective treatment modality in elderly patients with angina pectoris and significant coronary artery stenosis, compared to OMT."

For more information on this research see: Percutaneous Coronary Intervention Is

Health and Medicine - Medical Research

Researchers from Chung Ang University Hospital Detail New Studies and Findings in the Area of Medical Research (Intra-Articular Injections in Patients with Femoroacetabular Impingement: a Prospective, Randomized, Double-blind, Cross-over Study)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Health and Medicine - Medical Research is now available. According to news reporting out of Seoul, South Korea, by NewsRx editors, research stated, "We evaluated and compared the effectiveness of intra-articular injection of hip joint using hyaluronic acid and steroid in patients with femoroacetabular impingement (FAI). Thirty patients with FAI clinically and radiologically were enrolled and underwent hip injection using steroid (TA) or hyaluronic acid (HA) at 0-weeks with cross-over injection at 2-weeks in patients without clinical response of decrease of pain intensity less than 2-point."

Our news journalists obtained a quote from the research from Chung Ang University Hospital, "Patients were followed up to 12-weeks for pain intensity (Numeric rating scale, NRS: 0-10), hip disability score (HOOS), oral medication and adverse events. In 17 patients without crossover, HOOS at 2-weeks was improved significantly in patients with HA injection (mean increase of HOOS = 13.8 with HA vs. -2.2 with TA, P = 0.031) without difference of NRS (P = 0.943). In 13 patients with cross-over, NRS was significantly improved at 2-weeks with first TA injection (mean decrease of NRS = 1.7 with first TA vs. 0.3 with first HA, P = 0.036), without difference of HOOS (P = 0.431). At 4-weeks, NRS and HOOS were significantly different according to injection drugs (NRS: 0.9 with TA first and HA later vs. 2.7 with HA first and TA later, P = 0.001; mean increase of HOOS: 5.3 with TA first and HA later vs. 10.2 with HA first and TA later, P = 0.032)."

According to the news editors, the research concluded: "Intra-articular hip injection may be effective in FAI, with faster effect of pain improvement by TA and more delayed effect of function improvement by HA."

For more information on this research see: Intra-Articular Injections in Patients with Femoroacetabular Impingement: a Prospective, Randomized, Double-blind, Cross-over Study.
Researchers from Chung Ang University Report New Studies and Findings in the Area of Mononuclear Phagocyte System (Thunbergia alata inhibits inflammatory responses through the inactivation of ERK and STAT3 in macrophages)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Immunology - Mononuclear Phagocyte System have been published. According to news reporting originating from Seoul, South Korea, by NewsRx correspondents, research stated, "Thunbergia alata (Acanthaceae) has been used traditionally to treat various inflammatory diseases such as fever, cough and diarrhea in East African countries including Uganda and Kenya. However, systemic studies elucidating the anti-inflammatory effects and precise mechanisms of action of T. alata have not been conducted, to the best of our knowledge."

Our news editors obtained a quote from the research from Chung Ang University, "To address these concerns, we explored the anti-inflammatory effects of a methanol extract of T. alata (MTA) in macrophages. Non-cytotoxic concentrations of MTA (300 g/ml) inhibited nitric oxide (NO) production in lipopolysaccharide (LPS)-stimulated RAW 264.7 macrophages by transcriptional regulation of inducible NO synthase in a dose-dependent manner. The expression of cyclooxygenase-2, the enzyme responsible for the production of prostaglandin E-2, was unchanged by MTA at the mRNA and protein levels. MTA treatment inhibited interleukin (IL)-6 inflammatory cytokines, including IL-6 and IL-1. Tumor necrosis factor-production and mRNA expression were not regulated by MTA treatment. The decreased production of inflammatory mediators by MTA was followed by the reduced phosphorylation of extracellular signal-regulated kinase (ERK) and signal transducer and activator of transcription 3 (STAT3). MTA treatment had no effect on activity of other mitogen-activated protein kinases (MAPKs), p38, c-Jun N-terminal kinase (JNK), and nuclear factor-B (NF-B)."

According to the news editors, the research concluded: "These results indicate that MTA selectively inhibits the excessive production of inflammatory mediators in LPS-stimulated murine macrophages by reducing the activity of ERK and STAT3, suggesting that MTA plays an important inhibitory role in the modulation of severe inflammation."

For more information on this research see: Thunbergia alata inhibits inflammatory responses through the inactivation of ERK and STAT3 in macrophages. *International Journal of Molecular Medicine*, 2016;38(5):1596-1604. *International Journal of Molecular Medicine* can be contacted at: Spandidos Publ Ltd, Pob 18179, Athens, 116 10, Greece.
Researchers from Chungnam National University Report Recent Findings in Toxicology and Pharmacology (Subacute toxicity evaluation of KR-33493, FAF1 inhibitor for a new anti-parkinson's disease agent, after oral administration in rats and dogs)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Drugs and Therapies - Toxicology and Pharmacology are discussed in a new report. According to news reporting from Daejeon, South Korea, by NewsRx journalists, research stated, "KR33493, a newly developed FAS-associated factor 1 (FAF1) inhibitor for Parkinson's disease, is being evaluated in a Phase I clinical trial. In the present study, the subchronic toxicity of KR33493 in Sprague-Dawley (SD) rats and beagle dogs was investigated at various oral doses for 28 and 14 days, respectively."

Financial support for this research came from Chungnam National University.

The news correspondents obtained a quote from the research from Chungnam National University, "During the study, food consumption, body weights, organ weights, gross findings, and mortality were examined; and ophthalmoscopy, electrocardiography, hematology, serum biochemistry, urinalysis, histopathology, and toxicokinetics were performed. In rats, weight gain decreased in both sexes at 500 mg/kg/day, with no significant differences. In dogs, some significant differences compared with the control were found during the trial; however, at the end of recovery periods, these were no longer observed and there was no dose correlation. Some histopathological findings were observed, but these were considered as incidental changes. Since no other significant changes were observed, doses above 500 and 1000 mg/kg KR33493 in rat and dogs, respectively, caused no observed adverse effects."

According to the news reporters, the research concluded: "Therefore, based on these results, the Phase 1 clinical trial for KR33493 was approved by the Korean Food & Drug Administration."

Our news journalists report that additional information may be obtained by contacting S.E. Yoo, Chungnam National University, Grad Sch New Drug Discovery & Dev, Daejeon, South Korea. Additional authors for this research include C. Yu, J.H. Lee, K.S. Moon,
Researchers from College of Medicine Report on Findings in Human Immunodeficiency Virus (Plasmablastic lymphoma in HIV patients: Experience at a tertiary care hospital in eastern India)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Human Immunodeficiency Virus is the subject of a report. According to news reporting originating from West Bengal, India, by NewsRx correspondents, research stated, "Plasmablastic lymphoma (PBL), a rare non-Hodgkin's lymphoma (NHL) variant specifically associated with human immunodeficiency virus/acquired immunodeficiency syndrome (HIV/AIDS), expresses well-differentiated plasma cell markers like CD138, bright CD38, and MUM1; but not conventional B-cell markers. It occurs at unusual sites like oral cavity and orbit, and has poor survival rates."

Our news editors obtained a quote from the research from the College of Medicine, "This study serves as a review of a clinical experience with six HIV patients with PBL and observes the spectrum of clinical presentations, histopathologies, and 1-year outcomes in PBL patients. This review of six PBL patients was conducted at a tertiary care hospital in eastern India using relevant radiological, histopathological, and immunohistological studies. Incidence of PBL among HIV patients was 0.58% (6/1,028). Mean CD4 count at presentation was 125.5 ± 71.1 cells/mL. Sites of involvement included pleura, lung parenchyma, suprarenal gland, pelvic cavity, and retroorbital space (one each). Immunohistopathology of biopsied sample in each patient revealed PBL (positive plasma cell markers MUM-1/IRF4, CD38, and CD138/syndecan; and negative of B-cell markers CD3, CD20, and CD30). Three (60%) were positive for Epstein Barr virus (EBV) immunoglobulin G (IgG). Five surviving patients received CHOP (cyclophosphamide, doxorubicin, vincristine, prednisone) regimen and attained partial remission (PR) after six cycles. Subsequently, three patients were started on EPOCH (etoposide, cyclophosphamide, doxorubicin, vincristine, prednisone) therapy; two attained near total regression after 6 months (four cycles). Overall, four patients remained alive with good quality of life at the end of 1 year of follow-up. PBL in HIV occurs at unusual sites with varying aggressivity."

According to the news editors, the research concluded: "This study is too small to comment on the long-term outcomes of PBL in HIV; however, coadministration of antiretroviral therapy (ART) with standard chemotherapy may improve survival."

The news editors report that additional information may be obtained by contacting S.
Nutritional and Metabolic Diseases and Conditions - …

Researchers from Columbia University Detail New Studies and Findings in the Area of Amyloidosis (Transthyretin Cardiac Amyloidosis in Older Americans)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Nutritional and Metabolic Diseases and Conditions - Amyloidosis are discussed in a new report. According to news reporting originating in New York City, New York, by NewsRx journalists, research stated, "Wild-type transthyretin cardiac amyloidosis (ATTRwt), formerly called senile cardiac amyloidosis (SCA), is almost exclusively a disorder of older adults. As the population ages, the diagnosis of ATTRwt will increase, making it the most common form of cardiac amyloidosis."

The news reporters obtained a quote from the research from Columbia University, "An important precondition to reduce underdiagnosis and misdiagnosis is to maintain a high index of suspicion for cardiac amyloidosis. Several clues can be gleaned from the clinical history, physical exam, electrocardiography, and noninvasive imaging techniques. Nuclear scintigraphy agents using Tc-99m-phosphate derivatives combined with assessment for monoclonal proteins are eliminating the need for tissue confirmation in ATTR. Morbidity and mortality from ATTRwt cardiac amyloid is high and the emergence of numerous therapies based on a biologic understanding of the pathophysiology of this condition, including drugs to inhibit the synthesis of TTR, stabilize TTR, and degrade or extract amyloid, provides new hope for those afflicted."

According to the news reporters, the research concluded: "This review briefly covers the epidemiology, pathophysiology, and clinical manifestations, as well as diagnostic strategies and treatment, of ATTR in older adults."

For more information on this research see: Transthyretin Cardiac Amyloidosis in Older Americans. *Journal of Cardiac Failure*, 2016;22Q(12):996-1003. *Journal of Cardiac Failure* can be contacted at: Churchill Livingstone Inc Medical Publishers, Curtis Center, Independence Square West, Philadelphia, PA 19106-3399, USA. 2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Peptide Proteins - Posterior Pituitary Hormones. According to news reporting originating in New York City, New York, by NewsRx journalists, research stated, "Premature cervical remodeling resulting in spontaneous preterm birth may begin with premature failure or relaxation at the internal os (termed 'funneling'). To date, we do not understand why the internal os fails or why funneling occurs in some cases of premature cervical remodeling."

The news reporters obtained a quote from the research from Columbia University, "Although the human cervix is thought to be mostly collagen with minimal cellular content, cervical smooth muscle cells are present in the cervix and can cause cervical tissue contractility. To understand why the internal os relaxes or why funneling occurs in some cases of premature cervical remodeling, we sought to evaluate cervical smooth muscle cell content and distribution throughout human cervix and correlate if cervical smooth muscle organization influences regional cervical tissue contractility. Using institutional review board-approved protocols, nonpregnant women <50 years old undergoing hysterectomy for benign indications were consented. Cervical tissue from the internal and external os were immunostained for smooth muscle cell markers (a-smooth muscle actin, smooth muscle protein 22 calponin) and contraction-associated proteins (connexin 43, cyclooxygenase-2, oxytocin receptor). To evaluate cervical smooth muscle cell morphology throughout the entire cervix, whole cervical slices were obtained from the internal os, midcervix, and external os and immunostained with smooth muscle actin. To correlate tissue structure with function, whole slices from the internal and external os were stimulated to contract with 1 mmol/L of oxytocin in organ baths. In separate samples, we tested if the cervix responds to a common tocolytic, nifedipine. Cervical slices from the internal os were treated with oxytocin alone or oxytocin + increasing doses of nifedipine to generate a dose response and half maximal inhibitory concentration. Student t test was used where appropriate. Cervical tissue was collected from 41 women. Immunohistochemistry showed cervical smooth muscle cells at the internal and external os expressed mature smooth muscle cell markers and contraction-associated proteins. The cervix exhibited a gradient of cervical smooth muscle cells. The area of the internal os contained 50-60% cervical smooth
muscle cells that were circumferentially organized in the periphery of the stroma, which may resemble a sphincter-like pattern. The external os contained approximately 10% cervical smooth muscle cells that were randomly scattered in the tissue. In organ bath studies, oxytocin stimulated the internal os to contract with more than double the force of the external os (1341 +/- 693 vs 523 +/- 536 integrated grams x seconds, respectively, P = .009). Nifedipine significantly decreased cervical tissue muscle force compared to timed vehicle control (oxytocin alone) at doses of 10(-5) mol/L (vehicle 47% +/- 15% vs oxytocin + nifedipine 24% +/- 16%, P = .007), 10(-4) mol/L (vehicle 46% +/- 16% vs oxytocin + nifedipine -4% +/- 20%, P = .003), and 10(-3) mol/L (vehicle 42% +/- 14% vs oxytocin + nifedipine -15% +/- 18%, P = .0006). The half maximal inhibitory concentration for nifedipine was 1.35 x 10(-5) mol/L. Our findings suggest a new paradigm for cervical tissue morphology-one that includes the possibility of a specialized sphincter at the internal os."

According to the news reporters, the research concluded: "This new paradigm introduces novel avenues to further investigate potential mechanisms of normal and premature cervical remodeling."

Our news correspondents report that additional information may be obtained by contacting J.Y. Vink, Columbia University, Medical Center, Dept. of Obstet & Gynecol, New York, NY, United States. in the literature. To compare a large series of frameless to frame-based stereotactic catheter placements for Ommaya reservoirs, with an aim to compare accuracy and complication rate between the two procedures. A consecutive series of 41 frame-based and 68 frameless Ommaya reservoir placement procedures performed at our institution from 1998 to 2013 was reviewed. Patient demographics, operative accuracy and complication rates for the two techniques were compared. Characteristics of the two groups were similar in diagnoses, age and other related factors. Comparison of frameless to frame-based stereotactic Ommaya catheter placement did not show significant differences in accuracy of placement, overall morbidity or mortality, or in any subcategory of complications."

According to the news reporters, the research concluded: "These findings suggest that frameless stereotactic Ommaya reservoir placement is as safe and accurate as the frame-based technique."

Our news correspondents report that additional information may be obtained by contacting B.C. Kennedy, Dept. of Neurological Surgery, Columbia University, New York, NY, United States. Additional authors for this research include L.T. Brown, R.J. Komotar and G.M McKhann.

searched the Cochrane Central Register of Controlled Trials (CENTRAL), PubMed and ClinicalTrials.gov to 25 March 2016. Selection criteria We included randomised trials of augmentation therapy with alpha-1 antitrypsin compared with placebo or no treatment. Data collection and analysis The two review authors independently selected trials, extracted outcome data and assessed the risk of bias. We included three trials (283 participants in the analyses) that ran for two to three years. All participants were ex-or never-smokers and had genetic variants that carried a high risk of developing COPD. Only one trial reported mortality data (one person of 93 died in the treatment group and three of 87 died in the placebo group). There was no information on harms in the oldest trial. Another trial reported serious adverse events in 10 participants in the treatment group and 18 participants in the placebo group. In the most recent trial, serious adverse events occurred in 28 participants in each group. None of the trials reported mean number of lung infections or hospital admissions. In the two trials that reported exacerbations, there were more exacerbations in the treatment group than in the placebo group, but the results of both trials included the possibility of no difference. Quality of life was similar in the two groups. Forced expiratory volume in one second (FEV1) deteriorated more in participants in the treatment group than in the placebo group but the confidence interval (CI) included no difference (standardised mean difference -0.19, 95% CI -0.42 to 0.05; P = 0.12). For carbon monoxide diffusion, the difference was -0.11 mmol/minute/kPa (95% CI -0.35 to 0.12; P = 0.34). Lung density measured by computer tomography (CT) scan deteriorated significantly less in the treatment group than in the placebo group (mean difference (MD) 0.86 g/L, 95% CI 0.31 to 1.42; P = 0.002). Several secondary outcomes were unreported in the largest and most recent trial whose authors had numerous financial conflicts of interest. Authors' conclusions This review update added one new study and 143 new participants, but the conclusions remain unchanged. Due to sparse data, we could not arrive at a conclusion about the impact of augmentation therapy on mortality, exacerbations, lung infections, hospital admission and quality of life, and there was uncertainty about possible harms.

According to the news reporters, the research concluded: "Therefore, it is our opinion that augmentation therapy with alpha-1 antitrypsin cannot be recommended."

For more information on this research see: Intravenous alpha-1 antitrypsin augmentation therapy for treating patients with alpha-1 antitrypsin deficiency and lung disease. Cochrane Database of Systematic Reviews, 2016;(9):1985-2011. Cochrane Database of Systematic Reviews can be contacted at: Wiley-Blackwell, 111 River St, Hoboken 07030-5774, NJ, USA.

Researchers from Copenhagen University Hospital Report New Studies and Findings in the Area of Hyperalgesia (Effects of target-controlled infusion of high-dose naloxone on pain and hyperalgesia in a human thermal injury model: a study protocol ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Nervous System Diseases and Conditions - Hyperalgesia. According to news reporting originating from Copenhagen, Denmark, by NewsRx correspondents, research stated, "Mu-opioid-receptor antagonists have been extensively studied in experimental research as pharmacological tools uncovering mechanisms of pain modulation by the endogenous opioid system. In rodents, administration of high doses of mu-opioid-receptor antagonists after the resolution of an inflammatory injury has demonstrated reinstatement of nociceptive hypersensitivity indicating unmasking of latent sensitization."

Our news editors obtained a quote from the research from Copenhagen University Hospital, "In a recent human study, pain hypersensitivity assessed as secondary hyperalgesia area (SHA), was reinstated 7 days after a mild thermal injury, in 4 out of 12 subjects after a naloxone infusion. The aims of the present study are first, to replicate our previous findings in a larger-sized study; second, to examine if high sensitizers (subjects presenting with large SHA after a thermal injury) develop a higher degree of hypersensitivity after naloxone challenge than low sensitizers (subjects presenting with restricted SHA after a thermal injury); and third to examine a dose-response relationship between stable naloxone concentrations controlled by target-controlled infusion, and the unmasking of latent sensitization. Healthy participants (n=80) underwent a screening day (day 0) with induction of a thermal skin injury (47 degrees C, 420 seconds, 12.5 cm(2)). Assessment of SHA was performed 1 and 2 hours after the injury. Using an enriched design, only participants belonging to the upper quartile of SHA (Q4, high sensitizers; n=20) and the lower quartile of SHA (Q1, low sensitizers; n=20) continued the study, comprising 4 consecutive days-days 1 to 4. Thermal skin injuries were repeated on day 1 and day 3, whereas day 2 and day 4 (7 days after day 1 and day 3, respectively) were target-controlled infusion days in which the subjects were randomly allocated to receive either naloxone (3.25 mg/kg, 4mg/mL) or placebo (normal saline) intravenous. The primary outcome was SHA assessed by weighted-pin instrument (128mN) 0, 1, 2, and 165 to 169 hours after the thermal injury (day 1-4). The secondary outcomes were pinprick pain thresholds assessed by weighted-pin instrument (8-512mN) at primary and secondary hyperalgesia areas (days 1-4).

The naloxone-induced unmasking of latent sensitization is an interesting model for exploring the transition from acute to chronic pain."

According to the news editors, the research concluded: "The results from the present study may provide valuable information regarding future research in persistent postsurgical pain states."

For more information on this research see: Effects of target-controlled infusion of high-dose naloxone on pain and hyperalgesia in a human thermal injury model: a study protocol A randomized, double-blind, placebo-controlled, crossover trial with an enriched design. Medicine, 2016;95(46):222-229. Medicine can be contacted at: Lippincott Williams & Wilkins, Two Commerce Sq, 2001 Market St, Philadelphia, PA 19103, USA. Researchers from Cukurova University Discuss Findings in Antidepressants (Dipyrone ameliorates behavioural changes induced by unpredictable chronic mild stress: gender differences)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Drugs and Therapies - Antidepressants. According to news originating from Adana, Turkey, by NewsRx correspondents, research stated, "Antidepressant effects of analgesics have been investigate in both clinical and experimental studies. The purpose of this study was to investigate if the analgesic-antipyretic drug, dipyrone, also had antidepressant-like effects."

Our news journalists obtained a quote from the research from Cukurova University, "Depression-like effects were investigated in an unpredictable chronic mild stress (UCMS) model in both male and female mice. Cage changes, light-dark cycle reversal, cage tilting, wet floor, empty cage, foreign material on the floor and predator sounds were used to induce light stress at different times for six weeks. Dipyrone was administered intraperitoneally beginning from the third week. Splash, rota-rod (RR) and forced swimming (FST) tests were performed at the seventh week as behavioural tests to evaluate the antidepressant-like effects of dipyrone. Coat state score (CSS) and weights of animals were recorded at seventh weeks. Results were analyzed using one or two-way ANOVA followed by the Bonferonni post hoc test. Weight of UCMS-exposed mice did not change compared with controls; however, significant changes were observed in CSS in both sexes of stressed mice (p <0.05). RR latency decreased and immobility time enhanced in FST test in both sexes of stressed mice (p <0.05). Grooming behaviour was not different between the groups in female mice, but different in male mice in the splash test. Dipyrone did not produce a significant change in CSS in the UCMS-exposed group but reversed the latency time and immobility time to normal values in both sexes of mice and augmented the number of grooming behaviour only in stressed male mice."

According to the news editors, the research concluded: "These results indicate that dipyrone produce antidepressant-like effects to some symptoms of UCMS according to gender."

For more information on this research see: Dipyrone ameliorates behavioural changes induced by unpredictable chronic mild stress: gender differences. Clinical and Investigative Medicine, 2016;39(6):S14-S20. Researchers from DZHK German Center for Cardiovascular Research Discuss Findings in Takotsubo Cardiomyopathy (Prognostic Usefulness of the Ballooning Pattern in Patients With Takotsubo Cardiomyopathy)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Heart Disorders and Diseases - Takotsubo Cardiomyopathy are presented in a new report. According to news originating from Lubeck, Germany, by NewsRx correspondents, research stated, "The aim of the present analysis was to evaluate the prognostic impact of different ballooning patterns in patients with Takotsubo cardiomyopathy (TTC). A total of 285 consecutive patients with TTC were included."

Our news journalists obtained a quote from the research from DZHK German Center for Cardiovascular Research, "Clinical characteristics and short- and long-term outcomes were compared between patients with typical apical ballooning (n = 204) and patients with an atypical ballooning pattern including midventricular and basal ballooning (n = 81). Patients with typical apical ballooning were significantly older (73.3 +/- 10.2 vs 68.4 +/- 10.3 years; p<0.01) and had a higher prevalence of diabetes mellitus (25.5% vs 12.3%; p = 0.02). The initial left ventricular (LV) ejection fraction was significantly lower in case of apical ballooning (41.5 +/- 10.4% vs 46.9 +/- 10.9%; p<0.01) but recovered to normal values in both groups (58.4 +/- 8.0 vs 59.7 +/- 7.0; p = 0.25). Although 28-day mortality did not differ significantly (p = 0.10), typical apical ballooning was associated with an increased 6-month (13.4% vs 1.3%; hazard ratio [HR] 10.81, 95% confidence interval [CI] 1.47 to 79.66; p = 0.02) and long-term mortality rates (28.9% vs 14.5%; HR 2.24, 95% CI 1.17 to 4.71; p = 0.02). A landmark analysis which included only patients who survived the first 6 months after the initial event demonstrated similar mortality rates in patients with typical (17.9%) and atypical (13.3%) ballooning (HR 1.36, 95% CI 0.67 to 2.79; p = 0.40)."

According to the news editors, the research concluded: "In patients with TTC, typical apical ballooning is associated with more severe LV dysfunction at acute presentation and higher mortality rates within the first 6 months after the initial event. After complete recovery of LV function, prognosis is similar in patients with typical and atypical ballooning patterns."

The news correspondents report that additional information may be obtained from I.
Researchers from DZHK German Center for Cardiovascular Research
Report New Studies and Findings in the Area of Gene Therapy (Viral Vector-Based Targeting of mirt-21 in Cardiac Nonmyocyte Cells Reduces Pathologic Remodeling of the Heart)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Biotechnology - Gene Therapy is now available. According to news reporting from Munich, Germany, by NewsRx journalists, research stated, "Systemic inhibition of miR-21 has proven effective against myocardial fibrosis and dysfunction, while studies in cardiac myocytes suggested a protective role in this cell type. Considering potential implications for therapy, we aimed to determine the cell fraction where miR-21 exerts its pathological activity."

The news correspondents obtained a quote from the research from DZHK German Center for Cardiovascular Research, "We developed a viral vector-based strategy for gene targeting of nonmyocyte cardiac cells in vivo and compared global to cardiac myocyte-specific and nonmyocyte-specific deletion of miR-21 in chronic left ventricular pressure overload. Murine moloney virus and serotype 9 of adeno-associated virus were engineered to encode improved Cre recombinase for genetic deletion in miR-21(f/f) mice. Pericardial injection of murine moloney virus-improved Cre recombinase to neonates achieved highly selective genetic ablation of miR-21 in nonmyocyte cardiac cells, identified as cardiac fibroblasts and endothelial cells. Upon left ventricular pressure overload, cardiac function was only preserved in mice with miR-21 deficiency in nonmyocyte cardiac cells, but not in mice with global or cardiac myocyte-specific ablation."

According to the news reporters, the research concluded: "Our data demonstrate that miR-21 exerts its pathologic activity directly in cardiac nonmyocytes and encourage further development of antimiR-21 therapy toward cellular tropism."

For more information on this research see: Viral Vector-Based Targeting of mirt-21 in Cardiac Nonmyocyte Cells Reduces Pathologic Remodeling of the Heart. *Molecular Therapy*, 2016;24(11):1939-1948. *Molecular Therapy* can be contacted at: Nature Publishing Group, 75 Varick St, 9TH Flr, New York, NY 10013-1917, USA. Researchers from Denver Health Medical Center Report on Findings in Cardiac Arrhythmias (Evaluation and Management of Maternal Cardiac Arrhythmias)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Heart Disorders and Diseases - Cardiac Arrhythmias have been published. According to news reporting out of Denver, Colorado, by NewsRx editors, research stated, "Pregnant women often complain of palpitations. The differential diagnosis for new-onset palpitations in pregnancy ranges from benign conditions to life-threatening arrhythmias."

Our news journalists obtained a quote from the research from Denver Health Medical Center, "Maternal arrhythmias can occur in isolation or in the setting of underlying structural heart disease. Optimal management of maternal cardiac arrhythmias includes identification of the specific arrhythmia, diagnosis of comorbid conditions, and appropriate intervention. In general, management of maternal cardiac arrhythmias is similar to that of the general population. Special consideration must be given as to the effects of medications and procedures on both the mother and fetus to optimize outcomes."

According to the news editors, the research concluded: "The importance of multidisciplinary care with cardiology, obstetrics, and anesthesia is emphasized."

Our news journalists report that additional information may be obtained by contacting T.D. Metz, Denver Hlth Med Center, Dept. of Obstet & Gynecol, Denver, CO 80204, United States.

Mosquito-Borne Diseases - West Nile Fever

Researchers from Department of Biological Science Describe Findings in West Nile Fever (TLR8 Couples SOCS-1 and Restrains TLR7-Mediated Antiviral Immunity, Exacerbating West Nile Virus Infection in Mice)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Mosquito-Borne Diseases - West Nile Fever have been published. According to news reporting from Hattiesburg, Mississippi, by NewsRx journalists, research stated, "West Nile virus (WNV) is a neurotropic ssRNA flavivirus that can cause encephalitis, meningitis, and death in humans and mice. Human TLR7 and TLR8 and mouse TLR7 recognize viral ssRNA motifs and induce antiviral immunity."

The news correspondents obtained a quote from the research from the Department of Biological Science, "However, the role of mouse TLR8 in antiviral immunity is poorly understood. In this article, we report that TLR8-deficient (Tlr8(-/-)) mice were resistant to WNV infection compared with wild-type controls. Efficient WNV clearance and moderate susceptibility to WNV-mediated neuronal death in Tlr8(-/-) mice were attributed to overexpression of Tlr7 and IFN-stimulated gene-56 expression, whereas reduced expression of the proapoptotic gene coding Bcl2-associated X protein was observed. Interestingly, suppressor of cytokine signaling (SOCS)-1 directly associated with TLR8, but not with TLR7, indicating a novel role for TLR8 regulation of SOCS-1 function, whereas selective small interfering RNA knockdown of Socs-1 resulted in induced IFN-stimulated gene-56 and Thr7 expression following WNV infection."

According to the news reporters, the research concluded: "Collectively, we report that TLR8 coupling with Socs-1 inhibits TLR7-mediated antiviral immunity during WNV infection in mice."

For more information on this research see: TLR8 Couples SOCS-1 and Restrains TLR7-Mediated Antiviral Immunity, Exacerbating West Nile Virus Infection in Mice. Researchers from Department of Cardiology Provide Details of New Studies and Findings in the Area of Heart Attack (Fragmented QRS on Admission Electrocardiography Predicts Long-Term Mortality in Patients with Non-ST-Segment Elevation Myocardial ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Heart Disorders and Diseases - Heart Attack. According to news reporting from Istanbul, Turkey, by NewsRx journalists, research stated, "Early diagnosis and identification of high-risk non-ST elevation myocardial infarction (NSTEMI) is an important issue. Fragmented QRS (fQRS) complexes are defined as various RSR' patterns on 12-lead resting electrocardiography (ECG)."

The news correspondents obtained a quote from the research from the Department of Cardiology, "Previous studies revealed that fQRS is related with increased ventricular arrhythmias and cardiovascular mortality. The relation between fQRS and mortality in acute coronary syndromes, mitral valve disease severity and structural heart disease has been shown in different studies. The aim of this study was to investigate relation between fQRS and long-term cardiovascular mortality in NSTEMI patients. Patients who admitted to our emergency unit and diagnosed NSTEMI between 2012 and 2013, 433 patients were included prospectively. fQRS complexes determined in 85 patients. Patients were divided into two groups according to fQRS existence. All patients evaluated for their clinical, laboratory, electrocardiographic, and echocardiographic characteristics. Angiographic features of 315 patients who underwent coronary angiography was also recorded. In-hospital, 30-day and 12-month mortality was compared between these groups. Demographic characteristics and cardiovascular risk factors were similar in both groups except hyperlipidemia. GRACE risk score was higher in patients with fQRS and positively correlated with existence of fQRS. In hospital and 30-days mortality were similar but late mortality was higher in fQRS group. Predictors of late mortality were found to be age, heart rate, male sex in addition to fQRS. We found a relation between fQRS and late mortality."

According to the news reporters, the research concluded: "Fragmented QRS may be seen as a cautionary signal for extensive myocardial damage and thereby increased long-term mortality for patients with NSTEMI."

Our news journalists report that additional information may be obtained by contacting O. Yildirimturk, Siyami Ersek Thorac & Cardiovasc Surg Training & Dept. of Cardiol, Istanbul, Turkey. Researchers from Department of Cardiology Report Findings in Endocarditis (Comparison of prognoses of Staphylococcus aureus left-sided prosthetic endocarditis and prosthetic endocarditis caused by other pathogens)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Heart Disorders and Diseases - Endocarditis are presented in a new report. According to news reporting originating in Amiens, France, by NewsRx journalists, research stated, "Staphylococcus aureus prosthetic valve endocarditis (SAPIE) is a serious disease. Our objective was to study the clinical, echocardiographic and prognostic characteristics of left-sided SAPIE, and to compare these characteristics with those of left-sided non-S. aureus prosthetic infective endocarditis (NSAPIE) (i.e. left-sided prosthetic infective endocarditis caused by another germ)."

The news reporters obtained a quote from the research from the Department of Cardiology, "This was a retrospective analysis of 35 cases of SAPIE among 247 cases of left-sided prosthetic valve endocarditis hospitalized at two university hospitals (Amiens and Marseille, France). SAPIE accounted for 14.1% of the cases of left-sided prosthetic valve endocarditis. SAPIE complications included heart failure (in 42.8% of cases), acute renal failure (in 51.4%), sepsis (in 51.4%), neurological events (in 31.4%), systemic embolic event (in 34.2%) and abscess (in 60.0%). In-hospital mortality occurred in 48.5% of SAPIE cases compared with 16% of NSAPIE cases. A comparison of the SAPIE and NSAPIE groups showed a significant difference in terms of 4-year survival (31.8 +/- 7.3% vs 60.1 +/- 4.1%; P= 0.001). Severe sepsis was the only prognostic factor associated with in-hospital mortality (odds ratio 5.7; P=0.03) and. long-term mortality (odds ratio 3.7; P=0.01) in cases of SAPIE. Sepsis-induced multiple organ dysfunction syndrome was the main cause of in-hospital mortality (70.5%). SAPIE is a very serious disease, with elevated in-hospital mortality resulting from sepsis-induced multiple organ dysfunction syndrome."

According to the news reporters, the research concluded: "Emergency surgery is recommended in these cases, when possible, before the occurrence of complications, especially severe sepsis."

For more information on this research see: Comparison of prognoses of Staphylococcus aureus left-sided prosthetic endocarditis and prosthetic endocarditis caused by other pathogens. Archives of Cardiovascular Diseases, 2016;109(10):542-549. Archives of Cardiovascular Diseases can be contacted at: Elsevier Masson, Via Paleocapa 7, 20121 Milano, Italy. (Elsevier - www.elsevier.com; Archives of Cardiovascular Diseases - www.journals.elsevier.com/archives-of-cardiovascular-diseases/)

Our news correspondents report that additional information may be obtained by contacting C. Tribouilloy, CHU Amiens Picardie, Dept. of Cardiol, F-80054 Amiens 1, France. Additional authors for this research include G. Habib, J.P. Remadi, E. Salaun, J.P. Casalta and C. Tribouilloy.

Researchers from Department of Cellular Biology Describe Findings in Alzheimer Disease (Overexpression of Metallothionein-1 Modulates the Phenotype of the Tg2576 Mouse Model of Alzheimer's Disease)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Neurodegenerative Diseases and Conditions - Alzheimer Disease. According to news reporting originating from Barcelona, Spain, by NewsRx correspondents, research stated, "Alzheimer's disease (AD) is the most commonly diagnosed dementia, where signs of neuroinflammation and oxidative stress are prominent. In this study we intend to further characterize the roles of the antioxidant, anti-inflammatory, and heavy metal binding protein, metallothionein-1 (MT-1), by crossing Mt1 overexpressing mice with a well-known mouse model of AD, Tg2576 mice, which express the human amyloid-b protein precursor (hAbPP) with the Swedish K670N/M671L mutations."

Our news editors obtained a quote from the research from the Department of Cellular Biology, "Mt1 overexpression increased overall perinatal survival, but did not affect significantly hAbPP-induced mortality and weight loss in adult mice. Amyloid plaque burden in &sim;14-month-old mice was increased by Mt1 overexpression in the hippocampus but not the cortex. Despite full length hAbPP levels and amyloid plaques being increased by Mt1 overexpression in the hippocampus of both sexes, oligomeric and monomeric forms of Ab, which may contribute more to toxicity, were decreased in the hippocampus of females and increased in males. Several behavioral traits such as exploration, anxiety, and learning were altered in Tg2576 mice to various degrees depending on the age and the sex. Mt1 overexpression ameliorated the effects of hAbPP on exploration in young females, and potentiated those on anxiety in old males, and seemed to improve the rate of spatial learning (Morris water maze) and the learning elicited by a classical conditioning procedure (eye-blink test)."

According to the news editors, the research concluded: "These results clearly suggest that MT-1 may be involved in AD pathogenesis."

The news editors report that additional information may be obtained by contacting Y. Manso, Animal Physiology Unit, Dept. of Cellular Biology, Physiology and Immunology,
Researchers from Department of Chemical Engineering Report on Findings in Biotechnology (Controlling the time evolution of mAb N-linked glycosylation, Part I: Microbioreactor experiments)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Biotechnology have been published. According to news reporting from Prague, Czech Republic, by NewsRx journalists, research stated, "N-linked glycosylation is of key importance for the efficacy of many biotherapeutic proteins such as monoclonal antibodies (mAbs). Media components and cell culture conditions have been shown to significantly affect N-linked glycosylation during the production of glycoproteins using mammalian cell fed-batch cultures."

The news correspondents obtained a quote from the research from the Department of Chemical Engineering, "These parameters inevitably change in modern industrial processes with concentrated feed additions and cell densities beyond 2 x 10(7) cells/mL. In order to control the time-dependent changes of protein glycosylation, an automated microbioreactor system was used to investigate the effects of culture pH, ammonia, galactose, and manganese chloride supplementation on nucleotide sugars as well as mAb N-linked glycosylation in a time-dependent way. Two different strategies comprising of a single shift of culture conditions as well as multiple media supplementations along the culture duration were applied to obtain changing and constant glycosylation profiles. The different feeding approaches enabled constant glycosylation patterns throughout the entire culture duration at different levels."

According to the news reporters, the research concluded: "By modulating the time evolution of the mAb glycan pattern, not only the endpoint but also the ratios between different glycosylation structures could be modified."

Our news journalists report that additional information may be obtained by
Researchers from Department of Electrophysiology Describe Findings in Atrial Fibrillation [Box Isolation of Fibrotic Areas (BIFA): A Patient-Tailored Substrate Modification Approach for Ablation of Atrial Fibrillation]

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Heart Disorders and Diseases - Atrial Fibrillation. According to news reporting out of Zurich, Switzerland, by NewsRx editors, research stated, "Catheter ablation strategies beyond pulmonary vein isolation (PVI) for treatment of atrial fibrillation (AF) are less well defined. Increasing clinical data indicate that atrial fibrosis is a critical common left atrial (LA) substrate in AF patients (pts)."

Our news journalists obtained a quote from the research from the Department of Electrophysiology, "We applied a new substrate modification concept according to the individual fibrotic substrate as estimated from electroanatomic voltage mapping (EAVM) in 41 pts undergoing catheter ablation of AF. First, EAVM during sinus rhythm was done in redo cases of 10 pts with paroxysmal AF despite durable PVI. Confluent low-voltage areas (LVA) were found in all pts and were targeted with circumferential isolation, so-called box isolation of fibrotic areas (BIFA). This strategy led to stable sinus rhythm in 9/10 pts and was transferred prospectively to first procedures of 31 pts with nonparoxysmal AF. In 13 pts (42%), no LVA (<0.5 mV) were identified, and only PVI was performed. In 18 pts (58%), additional BIFA strategies were applied (posterior box in 5, anterior box in 7, posterior plus anterior box in 5, no box in 1 due to diffuse fibrosis). Mean follow-up was 12.5 ± 2.4 months. Single-procedure freedom from AF/atrial tachycardia was achieved in 72.2% of pts and in 83.3% of pts with 1.17 procedures/patient. In approximately 40% of pts with nonparoxysmal AF, no substantial LVA were identified, and PVI alone showed high success rate."

According to the news editors, the research concluded: "In pts with paroxysmal AF despite durable PVI and in approximately 60% of pts with nonparoxysmal AF, individually localized LVA were identified and could be targeted successfully with the BIFA strategy."

Our news journalists report that additional information may be obtained by contacting H. Kottkamp, Hirslanden Hospital, Dept. of Electrophysiology, Zurich, Switzerland. Additional authors for this research include J. Berg, R. Bender, A. Rieger and D. Schreiber.
Researchers from Department of Infectious Disease Detail Findings in Antifungals (Posaconazole Therapeutic Drug Monitoring in a Regional Hospital Setting)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Drugs and Therapies - Antifungals. According to news reporting out of Wollongong, Australia, by NewsRx editors, research stated, "Posaconazole therapeutic drug monitoring (TDM) is recommended to promote effective antifungal prophylaxis, but its utility has yet to be optimized. Breakthrough invasive fungal infections have been reported with serum concentrations <700 mcg/L, but there is little evidence to determine the optimal serum concentration for efficacy or concentrations associated with toxicity."

Our news journalists obtained a quote from the research from the Department of Infectious Disease, "Challenges for effective monitoring are greater in settings without posaconazole TDM facilities because of the long turnaround time before receipt of results. Thirty-eight TDM episodes were performed on 18 patients in a regional center in Australia during a 30-month period. Australian guidelines recommend a trough serum concentration of <= 700 mcg/L. The response to concentrations below the recommendation threshold (700 mcg/L), the final serum plasma concentration for each patient, and the appropriateness of TDM were evaluated. A total of 19 (50%) concentrations were recorded to be, 700 mcg/L. Of these 19 concentrations, the drug dose was increased on only 4 occasions. Eleven of 18 patients (61%) had initial concentrations,700 mcg/L, with only 3 (27%) among those achieving final concentration <= 700 mcg/L; 5 patients with initial concentrations,700 mcg/L did not have any further TDM testing. Nine of the 18 (50%) patients had a final concentration,700 mcg/L. Five of 7 (71%) patients with initial concentrations >= 700 mcg/L had further TDM with no reasoning documented. The results demonstrate a lack of confidence and consistency in ordering, interpreting, and following up posaconazole concentrations. Therefore, the use of TDM should be carefully considered, especially in regional centers."

According to the news editors, the research concluded: "Such settings should consider the practicalities of posaconazole TDM and try to improve the process to ensure consistency and optimization of patient care."

For more information on this research see: Posaconazole Therapeutic Drug Monitoring in a Regional Hospital Setting. Therapeutic Drug Monitoring. 2016;38(6):804-807. Therapeutic Drug Monitoring can be contacted at: Lippincott Williams & Wilkins, Two
Researchers from Department of Medicine Provide Details of New Studies and Findings in the Area of Thrombocytopenia (Platelets in Critical Illness)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Hematologic Diseases and Conditions - Thrombocytopenia have been published. According to news reporting originating in Amsterdam, Netherlands, by NewsRx editors, the research stated, "In patients with critical illness, thrombocytopenia is a frequent laboratory abnormality. However frequent this may occur, a low platelet count is not an epiphenomenon, but a marker with further significance."

The news reporters obtained a quote from the research from the Department of Medicine, "It is always important to assess the proper cause for thrombocytopenia in critically ill patients because different underlying disorders may precipitate different diagnostic and therapeutic management strategies. Platelets are part of the first-line defense of the body against bleeding; hence, thrombocytopenia may increase the risk of hemorrhage. In case of systemic inflammatory syndromes, such as the response to sepsis, disseminated intravascular platelet activation may occur. This will contribute to microvascular failure and thereby play a role in the development of organ dysfunction. Platelets are circulating blood cells that will normally not interact with the intact vessel wall but that may swiftly respond to endothelial disruption (which is often part of the pathogenesis of critical illness) by adhering to subendothelial structures, followed by interaction with each other, thereby forming a platelet aggregate. The activated platelet (phospholipid) membrane may form a suitable surface on which further coagulation activation may occur."

According to the news reporters, the research concluded: "A low platelet count is a strong and independent predictor of an adverse outcome in critically ill patients, thereby facilitating a simple and practically risk assessment in these patients and potentially guiding the use of complex or expensive treatment strategies."

For more information on this research see: Platelets in Critical Illness. Seminars In Thrombosis and Hemostasis, 2016;42(3):252-7. (Thieme - www.thieme.com)

Our news correspondents report that additional information may be obtained by contacting M. Levi, Dept. of Medicine, Academic Medical Centre, Meibergdreef, AZ Amsterdam, Netherlands.
Researchers from Department of Medicine Report New Studies and Findings in the Area of Hepatitis C Virus (Eighteen- to 30-year-olds more likely to link to hepatitis C virus care: an opportunity to decrease transmission)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Liver Diseases and Conditions - Hepatitis C Virus are discussed in a new report. According to news reporting out of Boston, Massachusetts, by NewsRx editors, research stated, "Hepatitis C virus (HCV) infection incidence among 18-to 30-year-olds is increasing and guidelines recommend treatment of active injection drug users to limit transmission. We aimed to: measure linkage to HCV care among 18-to 30-year-olds and identify factors associated with linkage; compare linkage among 18-to 30-year-olds to that of patients >30 years."

Financial supporters for this research include National Institute on Drug Abuse, National Center for Advancing Translational Sciences, National Institutes of Health.

Our news journalists obtained a quote from the research from the Department of Medicine, "We used the electronic medical record at an urban safety net hospital to create a retrospective cohort with reactive HCV antibody between 2005 and 2010. We report seroprevalence and demographics of seropositive patients, and used multivariable logistic regression to identify factors associated with linkage to HCV care. We defined linkage as having evidence of HCV RNA testing after reactive antibody. Thirty two thousand four hundred and eighteen individuals were tested, including 8873 between 18 and 30 years. The seropositivity rate among those ages 18-30 was 10%. In multivariate analysis, among those 18-30, diagnosis location (Outpatient vs Inpatient/ED) (OR 1.78, 95% CI 1.28-2.49) and number of visits after diagnosis (OR 5.30, 95% CI 3.91-7.19) were associated with higher odds of linking to care. When we compared linkage in patients ages 18-30 to that among those older than 30, patients in the 18-30 years age group were more likely to link to HCV care than those in the older cohort even when controlling for gender, ethnicity, socioeconomic status, birthplace, diagnosis location and duration of follow-up. Eighteen-to 30-year-olds are more likely to link to HCV care than their older counterparts."

According to the news editors, the research concluded: "During the interferon-free treatment era, there is an opportunity to prevent further HCV transmission in this population."

Our news journalists report that additional information may be obtained by contacting K.L. Young, Dept. of Medicine, Boston Medical Center, Boston, MA, United States. Additional authors for this research include W. Huang, C.R. Horsburgh, B.P. Linas and S.A Assoumou.

Drugs and Therapies - Antibiotics

Researchers from Department of Microbiology and Immunology Detail New Studies and Findings in the Area of Antibiotics (Protein aggregation as an antibiotic design strategy)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Drugs and Therapies - Antibiotics have been published. According to news reporting originating in Leuven, Belgium, by NewsRx journalists, research stated, "Taking advantage of the xenobiotic nature of bacterial infections, we tested whether the cytotoxicity of protein aggregation can be targeted to bacterial pathogens without affecting their mammalian hosts. In particular, we examined if peptides encoding aggregation-prone sequence segments of bacterial proteins can display antimicrobial activity by initiating toxic protein aggregation in bacteria, but not in mammalian cells."

Financial supporters for this research include VIB, University of Leuven, Funds for Scientific Research Flanders (FWO), Flanders Institute for Science and Technology (IWT), Federal Office for Scientific Affairs of Belgium (Belgian), IUAP, Swedish Foundation for Strategic Research, ERC Starting Independent Researcher Grant.

The news reporters obtained a quote from the research from the Department of Microbiology and Immunology, "Unbiased in vitro screening of aggregating peptide sequences from bacterial genomes lead to the identification of several peptides that are strongly bactericidal against methicillin-resistant Staphylococcus aureus. Upon parenteral administration in vivo, the peptides cured mice from bacterial sepsis without apparent toxic side effects as judged from histological and hematological evaluation. We found that the peptides enter and accumulate in the bacterial cytosol where they cause aggregation of bacterial polypeptides."

According to the news reporters, the research concluded: "Although the precise chain of events that leads to cell death remains to be elucidated, the ability to tap into aggregation-prone sequences of bacterial proteomes to elicit antimicrobial activity represents a rich and unexplored chemical space to be mined in search of novel therapeutic strategies to fight infectious diseases."

Our news correspondents report that additional information may be obtained by contacting N.G. Bednarska, Laboratory of Clinical Bacteriology and Mycology, Dept. of Microbiology and Immunology, KULeuven, Leuven, Belgium. Additional authors for this research include J. van Eldere, R. Gallardo, A. Ganesan, M. Ramakers, I. Vogel, P. Baatsen, A. Staes, M. Goethals, P. Hammarstrom, K.P. Nilsson, K. Gevaert, J. Schymkowitz and F. Rousseau.

Transplant Medicine - Kidney Transplants

Researchers from Department of Nephrology Provide Details of New Studies and Findings in the Area of Kidney Transplants (Desensitization Protocol in Recipients of Deceased Kidney Donor With Donor-Specific Antibody-Low Titers)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Transplant Medicine - Kidney Transplants. According to news reporting from Valencia, Spain, by NewsRx journalists, research stated, "Kidney transplantation is the better option for end-stage renal disease (ESRD), but for patients with human leukocyte antigen (HLA) sensitization, the wait times are significantly longer than for patients without antibodies. Many desensitization protocols have been described involving strong immunosuppression, the use of apheresis, and B-cell modulating therapies."

The news correspondents obtained a quote from the research from the Department of Nephrology, "We have designed a desensitization protocol from day 0 for deceased donor kidney transplantation. Our aim was to present our initial experience with five kidney transplant patients. All patients had a negative complement-dependent cytotoxicity cross-match. The desensitization protocol included five to seven doses of thymoglobulin (1.25 mg/kg) and three sessions of plasmapheresis (PP) within the first week after transplantation, with intravenous immunoglobulin (500 mg/kg) after each PP session and one dose of rituximab on day 8. The presence of donor-specific antibodies (DSA) was analyzed by use of Luminex technology; levels between 1000 and 3000 mean fluorescence intensity were considered for desensitization. The median age was 44 years and median renal replacement therapy time was 9 years. All recipients presented 1 to 3 DSA specificities. There were no severe side effects related to PP, infusion of intravenous immunoglobulin, or rituximab. The median follow-up period was 19.3 months. Median serum creatinine level at last follow-up was 1.7 mg/dL. A kidney biopsy was performed in all patients. Graft and patient survival was 100%. Until now, few data are available concerning whether HLA-incompatible kidney transplantation after desensitization would benefit patients with ERSD."
According to the news reporters, the research concluded: "The desensitization strategy using the combination of PP, low doses of intravenous immunoglobulin, and rituximab at our center resulted in a satisfactory clinical outcome."

Our news journalists report that additional information may be obtained by contacting J.K. Berga, Hosp Dr Peset, Dept. of Nephrol, Valencia 46017, Spain. Additional authors for this research include A.S. Calabuig, E.G. Martinez, N.P. Alcaraz, A.A. Bernabeu, J.C. Albiach, P.M. Vila, S.B. Catalan and L.P. Mateu.

Herpesvirus Diseases and Conditions - Herpes Zoster

Researchers from Department of Neurology Describe Findings in Herpes Zoster (Detection of varicella-zoster virus DNA during medullary and brainstem relapses in multiple sclerosis)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Herpesvirus Diseases and Conditions - Herpes Zoster is now available. According to news reporting from Bergen, Norway, by NewsRx journalists, research stated, "We describe three cases of patients with concomitant acute medullary or brainstem multiple sclerosis (MS) lesions and detectable spinal fluid varicella-zoster virus DNA. Herpes simplex virus PCR was also positive in two of the patients."

The news correspondents obtained a quote from the research from the Department of Neurology, "One patient was re-punctured 2 weeks following the relapse, with negative results. The PCR findings greatly delayed correct diagnosis and treatment in all three patients. Based on our cases, we propose that inflammatory medullary and brainstem lesions could result in viral leakage, and possibly viral reactivation, from destroyed sensory neurons, yielding false-positive cerebrospinal fluid PCR results."

According to the news reporters, the research concluded: "As this can have diagnostic and therapeutic consequences, further studies are warranted to evaluate the clinical relevance of these findings."

For more information on this research see: Detection of varicella-zoster virus DNA during medullary and brainstem relapses in multiple sclerosis. Bmj Case Reports, 2016;2016():. (BMJ Publishing Group - group.bmj.com/; Bmj Case Reports - casereports.bmj.com/)

Our news journalists report that additional information may be obtained by
Researchers from Department of Neurology Report Recent Findings in Parkinson’s Disease (Polyneuropathy in levodopa-treated Parkinson's patients)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Parkinson's disease are presented in a new report. According to news reporting originating from Gdansk, Poland, by NewsRx correspondents, research stated, "Recently published studies show that the prevalence of polyneuropathy (PNP) is higher in patients with Parkinson's disease (PD) than in age-matched controls. Its pathogenesis, however is a matter of controversy."

Our news editors obtained a quote from the research from the Department of Neurology, "The major hypothesis is the toxicity of high concentrations of homocysteine (Hcy) possibly related to levodopa (LD) therapy. The aim of the present study was to determine the prevalence of PNP, independent of other etiologies, and to determine the relationship to demographic and clinical factors in LD-treated Parkinson's patients. A total of 102 patients (51 patients with PD and 51 sex- and age-matched healthy controls) were enrolled in the study. The presence of any risk factors for PNP, ascertained from the history and laboratory tests, was an exclusion criterion. The Toronto Clinical Scoring System (TCSS) was used for clinical assessment of PNP. The objective assessment was based on electroneurography (ENG) studies in which motor nerves (peroneal and tibial nerves) as well as sensory nerves (sural and superficial peroneal nerves) were bilaterally examined. The severity of the disease was determined using the UPDRS scale (Unified Parkinson's Disease Rating Scale) and the Hoehn-Yahr (H-Y) scale. In the PD group, the clinical and neurophysiological indicators of PNP, manifested as a symmetrical and predominantly sensory axonal neuropathy, were more frequent then in the control group and observed in 43.1% vs. 13.7% and 15.7% vs. 2% of subjects respectively. The presence of PNP correlated with age and the severity of PD. Patients with PD and PNP had a higher level of Hcy as compared to PD patients without PNP, however the difference was not statistically significant. The frequency of PNP in PD patients is higher than in controls."

According to the news editors, the research concluded: "The characteristics and discrepancy between the number of patients with clinical and ENG detected PNP may suggest the small fiber neuropathy (SFN) as the dominant form of neuropathy in PD patients."

For more information on this research see: Polyneuropathy in levodopa-treated Parkinson's disease...
Researchers from Department of Radiology Describe Findings in Magnetic Resonance (Can Diffusion-weighted Magnetic Resonance Imaging Predict Survival in Patients with Cervical Cancer? A Meta-Analysis)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Magnetic Resonance is the subject of a report. According to news reporting out of Chengdu, People's Republic of China, by NewsRx editors, research stated, "Although diffusion-weighted magnetic resonance imaging (DWI) has been widely used in the diagnosis of cervical cancer, whether it can predict disease recurrence or survival remains inconclusive. This study aimed to systematically evaluate whether DWI can serve as a reliable prognostic predictor in patients with cervical cancer."

Our news journalists obtained a quote from the research from the Department of Radiology, "PubMed, the MEDLINE database and the Cochrane Library were searched for DWI studies with >12 months of prognostic data in patients with cervical cancer. Endpoints included tumor recurrence and death. Methodological quality was assessed using the Quality in Prognostic Studies (QUIPS) tool. Combined estimates of hazard ratios (HRs) were derived. Nine studies involving a total of 796 patients (mean/median age from 45.0 years to 62.9 years) met the inclusion criteria. Methodological quality was relatively high. Eight of the nine studies employed apparent diffusion coefficient (ADC) as an indicator of DWI results. Using disease-free survival (DFS) as an outcome measure, nine studies yielded a combined HR of 1.55 (95% confidence interval (CI): 1.23-1.95), and seven studies that employed pretreatment DWI yielded a combined HR of 1.50 (95% CI: 1.03-2.19), which indicated that unfavorable DWI results were..."
associated with an approximately 1.50-1.55-fold higher risk of tumor recurrence. The two studies investigating the impact of DWI results on overall survival (OS) reported HRs of 7.20 and 2.17, respectively."

According to the news editors, the research concluded: "DWI may serve as a predictor of tumor recurrence in patients with cervical cancer as showed by meta-analysis, and the quantified ADC as a suitable candidate indicator."

Our news journalists report that additional information may be obtained by contacting Y.T. Wang, Sichuan Academy Med Sci, Dept. of Radiol, Chengdu 610072, Sichuan, People's Republic of China. Additional authors for this research include Y.C. Li, L.L. Yin and H. Pu.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1016/j.ejrad.2016.10.011. This DOI is a link to an online electronic document that is either free or for purchase.

Therapeutics

Researchers from Department of Safety Assessment Report on Findings in Therapeutics (Safety Lead Optimization and Candidate Identification: Integrating New Technologies into Decision-Making)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Therapeutics. According to news reporting originating from South San Francisco, California, by NewsRx correspondents, research stated, "Discovery toxicology focuses on the identification of the most promising drug candidates through the development and implementation of lead optimization strategies and hypothesis-driven investigation of issues that enable rational and informed decision-making. The major goals are to [a] identify and progress the drug candidate with the best overall drug safety profile for a therapeutic area, [b] remove the most toxic drugs from the portfolio prior to entry into humans to reduce clinical attrition due to toxicity, and [c] establish a well-characterized hazard and translational risk profile to enable clinical trial designs."

Financial support for this research came from Genentech.

Our news editors obtained a quote from the research from the Department of Safety Assessment, "This is accomplished through a framework that balances the multiple considerations to identify a drug candidate with the overall best drug characteristics and provides a cogent understanding of mechanisms of toxicity. The framework components include establishing a target candidate profile for each program that defines the qualities of a successful candidate based on the intended therapeutic area, including the risk tolerance for liabilities;
evaluating potential liabilities that may result from engaging the therapeutic target (pharmacology-mediated or on-target) and that are chemical structure-mediated (off-target); and characterizing identified liabilities. Lead optimization and investigation relies upon the integrated use of a variety of technologies and models (in silico, in vitro, and in vivo) that have achieved a sufficient level of qualification or validation to provide confidence in their use. We describe the strategic applications of various nonclinical models (established and new) for a holistic and integrated risk assessment that is used for rational decision-making."

According to the news editors, the research concluded: "While this review focuses on strategies for small molecules, the overall concepts, approaches, and technologies are generally applicable to biotherapeutics."

The news editors report that additional information may be obtained by contacting D.M. Dambach, Dept. of Safety Assessment, Genentech, Inc , 1 DNA Way, South San Francisco, California 94080, United States. Additional authors for this research include D. Misner, M. Brock, A. Fullerton, W. Proctor, J. Maher, D. Lee, K. Ford and D. Diaz.

Peripheral Artery Disease

Researchers from Department of Surgery Report Details of New Studies and Findings in the Area of Peripheral Artery Disease (Short stature in men is associated with subclinical peripheral arterial disease)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Peripheral Artery Disease. According to news originating from Pori, Finland, by NewsRx correspondents, research stated, "Peripheral arterial disease (PAD) affects approximately 202 million individuals around the world and is associated with a high risk of myocardial infarction, stroke and death. Although there is a clear inverse association between adult height and the risk of cardiovascular disease, little is known about the relationship between height and PAD."

Our news journalists obtained a quote from the research from the Department of Surgery, "The aim of our study was to assess the relationship between subclinical PAD and height. In a cross-sectional cardiovascular risk factor study in southwestern Finland, ankle brachial index (ABI) and other risk factors were measured from a total of 972 cardiovascular risk subjects derived from the general population. None of them had previously diagnosed diabetes, cardiovascular or renal disease or intermittent claudication. Subjects with an ABI <= 0.90 were categorized as having subclinical PAD. The average age of the study subjects was 58.1 +/- 6.7 years for men and 58.8 +/- 6.9 years for women. The prevalence of subclinical PAD
was 5% (95% CI 3% - 7%) (23/455) among men and 5% (95% CI 3% - 7%) (26/517) among women. The mean ABI among men and women was 1.09 +/- 0.12 and 1.08 +/- 0.12, respectively. In men, there was an inverse association between height and the prevalence of subclinical PAD (p < 0.001) along with a positive association between height and ABI values (p < 0.001). In a multivariate model, height, age and current smoking status remained independent factors that were associated with subclinical PAD in men, whereas in women, only pulse pressure was associated with subclinical PAD.

According to the news editors, the research concluded: "Short stature in men is associated with subclinical PAD and lower ABI values."

For more information on this research see: Short stature in men is associated with subclinical peripheral arterial disease. Vasa-European Journal of Vascular Medicine, 2016;45 (6):486-490. Vasa-European Journal of Vascular Medicine can be contacted at: Verlag Hans Huber Hogrefe Ag, Laenggass-Strasse 76, Ch-3000 Bern 9, Switzerland.

The news correspondents report that additional information may be obtained from A. Heikkila, Satakunta Hosp Dist, Dept. of Surg, Pori, Finland. Additional authors for this research include M. Venermo, H. Kautiainen, P. Arnio and P. Korhonen.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1024/0301-1526/a000566. This DOI is a link to an online electronic document that is either free or for purchase.

Keywords for this news article include: Pori, Finland, Europe, Cardiology, Risk and Prevention, Diagnostics and Screening, Peripheral Artery Disease, Ankle Brachial Index, Cardiovascular, Department of Surgery.

Central Nervous System Diseases and Conditions —

Researchers from Department of Surgery Report on Findings in Cranial Nerve Injuries (Cranial nerve injury is associated with dual antiplatelet therapy use and cervical hematoma after carotid endarterectomy)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Central Nervous System Diseases and Conditions - Cranial Nerve Injuries are discussed in a new report. According to news reporting out of Florence, Italy, by NewsRx editors, research stated, "To determine predictors of cranial nerve injury (CNI) after carotid endarterectomy (CEA). Consecutive CEAs performed over a 5-year period were enrolled in this study."

Our news journalists obtained a quote from the research from the Department of Surgery, "Outcomes analyzed included 30-day major adverse event rate (composite of stroke, death, and myocardial infarction), death, stroke, disabling stroke, myocardial infarction, cervical hematoma and CNI rate, reoperation, and hospital readmission at 30 days. There were 1258 CEAs were included in the study, 1168 (93%) were performed using an eversion technique. Patients with symptoms comprised 27% of the cohort (n = 340). At 30 days, there were no deaths, 23 major adverse events (1.8%), 11 strokes (0.9%: nine minor, two major), 12 myocardial infarctions (0.9%), 41 cervical hematomas (3.3%), 9 reoperations (0.7%) and 10 hospital readmissions (0.8%). Median duration of stay was 1 day (interquartile range, 1-2 days). CNI rate at discharge was 2.3% (n = 29). Two patients (9%) had more than one cranial nerve
affected. The marginal mandibular branch of the facial nerve was most frequently involved (n = 16; 52%), followed by the hypoglossal (n = 9; 29%), the vagus (n = 4; 13%), and the spinal accessory nerve (n = 2; 6%). Horner's syndrome, consistent with an injury to the cervical sympathetic chain, occurred in 13 patients (1%) who had a true cranial nerve affected as well. The vast majority (94%) of these CNIs and all Horner's syndrome neurapraxias were transient; only the two accessory lesions persisted at their follow-up visit (median, 32 months; range, 8-72 months). Significant predictors for CNI included diabetes (odds ratio [OR], 2.5; 95% confidence interval [CI], 1.0-6.2; P = .048), cervical hematoma (OR, 41.7; 95% CI, 13.8-125.4; P < .001), and dual antiplatelet therapy (OR, 4.4; 95% CI, 1.7-11.4; P = .002). CNI is predominantly a transient complication, but is associated significantly with dual antiplatelet therapy use and the occurrence of a postoperative cervical hematoma."

According to the news editors, the research concluded: "Scrupulous attention to hemostasis might reduce the incidence of CNI."

Our news journalists report that additional information may be obtained by contacting E. Chisci, San Giovanni Dio Hosp, Dept. of Surg, Vasc & Endovasc Surg Unit, I-50124 Florence, Italy. Additional authors for this research include T.F. Rehring, C. Pigozzi, S. Colon, A. Borgheresi, L. Tramacere, L. Ercolini and S. Michelagnoli.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1016/j.jvs.2016.04.029. This DOI is a link to an online electronic document that is either free or for purchase.

**Gastroenterology**

Researchers from Department of Surgery Report on Findings in Gastroenterology (The role of surgical gastrostomy in the age of endoscopic gastrostomy: a 13 years and 543 patients retrospective study)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Gastroenterology have been presented. According to news originating from Almada, Portugal, by NewsRx correspondents, research stated, "Percutaneous endoscopic gastrostomy (PEG) became the gold standard for enteral feeding. Currently, surgical
gastrostomy is seldom used."

Our news journalists obtained a quote from the research from the Department of Surgery, "Evaluating the role of surgical gastrostomy in a center with a large experience in PEG. A retrospective study ranged 13 years, collecting from clinical records: age, gender, underlying disease, date of procedure, technique, primary surgery, complications, 30-day mortality. Patients were divided according to indication for gastrostomy: a) neurological; b) head and neck cancer; c) other diseases; and d) drainage. PEG, open surgical and laparoscopic gastrostomies were compared concerning evolution of the number of procedures, characteristics of patients, complications and mortality. We identified 509 PEG, 26 open and 8 laparoscopic surgical gastrostomies. An increasing number of the percutaneous approach over the years was observed, while the number of surgical gastrostomies remains steady (mean: 2.6/year). All percutaneous endoscopic gastrostomies but three were feeding procedures, mostly in neurological patients. All laparoscopic gastrostomies were feeding procedures in head and neck cancer. Most open surgical gastrostomies were secondary procedures, part of more complex surgeries, and frequently for drainage purposes. The open surgical approach displayed more morbidity and mortality, reflecting the severity of underlying diseases. In our institution, open surgical gastrostomy is seldom used, and mostly as part of complex procedures, frequently for drainage purposes. PEG is the choice to most dysphagic patients needing an enteral feeding access."

According to the news editors, the research concluded: "When not feasible, laparoscopic gastrostomy is a suitable alternative."

For more information on this research see: The role of surgical gastrostomy in the age of endoscopic gastrostomy: a 13 years and 543 patients retrospective study. Revista Española De Enfermedades Digestivas, 2016;108(12):776-779. Revista Española De Enfermedades Digestivas can be contacted at: Aran Ediciones, S A, Castello, 128, 1O, 28006 Madrid, Spain.

Nervous System Diseases and Conditions - Myoclonus

Researchers from Department of Surgery Report on Findings in Myoclonus (Cerebral hyperperfusion syndrome: A rare postoperative complication of carotid endarterectomy)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Nervous System Diseases and Conditions - Myoclonus. According to news originating from Joondalup, Australia, by NewsRx correspondents, research stated, "Acute neurological deficits are common presentations to the emergency department. Cerebral hyperperfusion syndrome, a rare phenomenon which can occur within one month following carotid surgical revascularization, may be challenging for the emergency physician to diagnose in the setting of an acute neurological presentation."
Our news journalists obtained a quote from the research from the Department of Surgery, "Carotid arterial disease contributes 15-20% of ischemic cerebrovascular accidents and surgical revascularization is the commonest intervention for preventing stroke in patients with significant carotid disease. However if the patient remains hypertensive postoperatively in the setting of sudden carotid reperfusion following revascularization, they are prone to cerebral hyperperfusion syndrome. Caused by increased, unregulated cerebral blood flow, cerebral hyperperfusion syndrome can result in cerebral edema and intracranial hemorrhage which may manifest in symptoms ranging from headaches, myoclonus, hemiparesis, seizures, reduced consciousness and potentially result in death. The most important facets in management of cerebral hyperperfusion syndrome in the emergency department is early recognition, prompt management and monitoring of hypertension (up to 81% of patients have severe hypertension at onset of neurological symptoms) and early imaging. We report a case of cerebral hyperperfusion syndrome in a woman who had ongoing severe hypertension following carotid endarterectomy. Five days following surgery and after discharge, she presented to the emergency department with worsening right upper limb myoclonus, tremor, weakness and hypertension."

According to the news editors, the research concluded: "Initially treated with anticonvulsants without resolution of symptoms, prompt imaging and management of hypertension in the emergency department resulted in the correct diagnosis and complete resolution of symptoms without any permanent neurological deficits."

The news correspondents report that additional information may be obtained from M. Guirgis, Joondalup Hlth Campus, Dept. of Surg, Joondalup, WA, Australia.

Keywords for this news article include: Joondalup, Australia, Australia and New Zealand, Cardiovascular Diseases and Conditions, Nervous System Diseases and Conditions, Hematologic Diseases and Conditions, Post-Operative Complications, Hyperperfusion Syndrome, Carotid Endarterectomy, Risk and Prevention, Hypertension, Hematology, Angiology, Myoclonus, Surgery, Stroke, Department of Surgery.

Oncology - Liver Cancer

Researchers from Dokuz Eylul University Detail Findings in Liver Cancer (Role of Fanconi anemia/BRCA pathway genes in hepatocellular carcinoma chemoresistance)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Oncology - Liver Cancer. According to news reporting originating in Izmir, Turkey, by NewsRx journalists, research stated, "To investigate the expression of DNA repair genes and the impact of the breast cancer 1, early onset (BRCA1) protein on chemoresistance of hepatocellular carcinoma (HCC). Microarray gene expression datasets were analyzed using the gene set enrichment analysis method."
The news reporters obtained a quote from the research from Dokuz Eylul University, "BRCA1 protein was tested by Western blotting. Response of HCC cells to inter-strand cross-links was investigated by cell viability assay following exposure to mitomycin C, cisplatin, and melphalan. Effects of BRCA1 ectopic expression were studied in HepG2 cells with BRCA1-expression plasmids. Effects of BRCA1 downregulation were studied in SNU449 cells with BRCA1-specific siRNAs. Response of transfected SNU449 cells to mitomycin C was analyzed by cell viability tests and cell cycle analysis using flow cytometry. Expression of Fanconi anemia and double-stranded DNA break repair genes was significantly upregulated in HCC tumors. This upregulation displayed a gradual amplification during tumor progression. BRCA1 and BRCA2 genes were among consistently upregulated genes. Epithelial-like HCC cells had low BRCA1 expression and low chemoresistance, whereas mesenchymal-like HCC cells had high BRCA1 expression and increased chemoresistance. Ectopic expression of BRCA1 increased the chemoresistance of epithelial-like HepG2 cells. Conversely, BRCA1 knockdown chemosensitized mesenchymal-like SNU449 cells. Chemosensitization of SNU449 cells was due to cell cycle arrest at 4N stage. Increased expression of Fanconi anemia and double-stranded DNA repair genes such as BRCA1 is a novel mechanism of HCC chemoresistance."

According to the news reporters, the research concluded: "However, functional inactivation of BRCA1 expression is sufficient to reverse such chemoresistance."

Our news correspondents report that additional information may be obtained by contacting M. Ozturk, Dokuz Eylul University, Izmir Int Biomed & Genome Inst, Izmir, Turkey. Additional authors for this research include G. Yildiz, M. Bouras, E. Iscan, U. Ekin and M. Ozturk.

developed a 2'F modified RNA aptamer Ec3, by Cell-SELEX."

Our news journalists obtained a quote from the research from Dongguk University, "The 31 nucleotide truncated Ec3 demonstrated improved binding and low nano-molar affinity to E. coli. The aptamer developed by us out-performs the commercial antibody and aptamer used for E. coli detection. Ec3(31) aptamer based E. coli detection was done using three different detection formats and the assay sensitivities were determined. Conventional Ec3(31)-biotin-streptavidin magnetic separation could detect E. coli with a limit of detection of 1.3 x 10 (6) CFU/ml. Although, optical analytic technique, biolayer interferometry, did not improve the sensitivity of detection for whole cells, a very significant improvement in the detection was seen with the E. coli cell lysate (5 x 10(4) CFU/ml). Finally we developed Electrochemical Impedance Spectroscopy (EIS) gap capacitance biosensor that has detection limits of 2 x 10(4) CFU/mL of E. coli cells, without any labeling and signal amplification techniques."

According to the news editors, the research concluded: "We believe that our developed method can step towards more complex and real sample application."

The news correspondents report that additional information may be obtained from S. Kim, Dongguk Univ, Dept. of Bioengn, Seoul 04620, South Korea. Additional authors for this research include S. Ren, S.W. Lee, J.K. Kim, H.S. Shin, O.C. Jeong, S. Kim and D.K. Lee.

Hormones

Researchers from Dr. Hari Singh Gour University Report Recent Findings in Hormones (Luteinizing hormone-releasing hormone peptide tethered nanoparticulate system for enhanced antitumoral efficacy of paclitaxel)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Hormones have been published. According to news reporting out of Sagar, India, by NewsRx editors, research stated, "Paclitaxel (PTX) is an effective anticancer agent used in the therapy of a wide variety of cancers. However, the drug is difficult to formulate due to its low solubility, and therefore, it is administered under slow infusion with castor oil/ethanol solution as surfactant that causes serious side effects."

Our news journalists obtained a quote from the research from Dr. Hari Singh Gour University, "This investigation investigates leutinizing hormone releasing hormone (LHRH)-
tethered nanparticulate system as modality for cancer-specific delivery of PTX and therefore minimizing the adverse effects. LHRH-tethered poly(lactic-co-glycolic acid) copolymer with poly ethylene glycol side chain was synthesized, characterized and employed to formulate PTX-loaded nanparticulate system."

According to the news editors, the research concluded: "The developed nanparticulate appears to be proficient in carrying as well as targeted delivery of PTX with improved therapeutic efficacy and better safety."

For more information on this research see: Luteinizing hormone-releasing hormone peptide tethered nanoparticulate system for enhanced antitumoral efficacy of paclitaxel. *Nanomedicine*, 2016;11(7):797-816. (Elsevier - www.elsevier.com; Nanomedicine - www.journals.elsevier.com/nanomedicine-nanotechnology-biology-and-medicine/)

Our news journalists report that additional information may be obtained by contacting R. Ghanghoria, Pharmaceutics Research Laboratory, Dept. of Pharmaceutical Sciences, Dr Hari Singh Gour University, Sagar 470003 MP, India. Additional authors for this research include R.K. Tekade, A.K. Mishra, K. Chuttani and N.K Jain.

**Immune System Diseases and Conditions - HIV/AIDS**

**Researchers from Duke University Describe Findings in HIV/AIDS (Immunization with an SIV-based IDLV Expressing HIV-1 Env 1086 Clade C Elicits Durable Humoral and Cellular Responses in Rhesus Macaques)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Immune System Diseases and Conditions - HIV/AIDS are presented in a new report. According to news reporting originating from Durham, North Carolina, by NewsRx correspondents, research stated, ""The design of an effective HIV-1 vaccine remains a major challenge. Several vaccine strategies based on viral vectors have been evaluated in preclinical and clinical trials, with largely disappointing results."

Our news editors obtained a quote from the research from Duke University, ""Integrase defective lentiviral vectors (IDLV) represent a promising vaccine candidate given their ability to induce durable and protective immune responses in mice after a single immunization. Here, we evaluated the immunogenicity of a SIV-based IDLV in nonhuman primates. Six rhesus monkeys were primed intramuscularly with IDLV-Env and boosted with the same vector after 1 year. A single immunization with IDLV-Env induced broad humoral and cellular immune responses that waned over time but were still detectable at 1 year postprime. The boost with IDLV-Env performed at 1 year from the prime induced a remarkable increase in both antibodies and T-cell responses. Antibody binding specificity showed a predominant cross-
clade gp120-directed response. Monkeys' sera efficiently blocked anti-V2 and anti-CD4 binding site antibodies, neutralized the tier 1 MW965.26 pseudovirus and mediated antibody-dependent cellular cytotoxicity (ADCC). Durable polyfunctional Env-specific T-cell responses were also elicited. Our study demonstrates that an IDLV-Env-based vaccine induces functional, comprehensive, and durable immune responses in Rhesus macaques."

According to the news editors, the research concluded: "These results support further evaluation of IDLV as a new HIV-1 vaccine delivery platform."

For more information on this research see: Immunization with an SIV-based IDLV Expressing HIV-1 Env 1086 Clade C Elicits Durable Humoral and Cellular Responses in Rhesus Macaques. Molecular Therapy, 2016;24(11):2021-2032. Molecular Therapy can be contacted at: Nature Publishing Group, 75 Varick St, 9TH Flr, New York, NY 10013-1917, USA. Peripheral Artery Disease

Researchers from Duke University Describe Findings in Peripheral Artery Disease (Concomitant Thoracic Aortobifemoral Bypass With Left Ventricular Assist Device Implantation)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Peripheral Artery Disease. According to news reporting originating from Durham, North Carolina, by NewsRx correspondents, research stated, "Improved quality of life for patients after left ventricular assist device (LVAD) implantation can be greatly limited by peripheral vascular disease even if heart failure symptoms are resolved by LVAD support. We present a case of concomitant thoracic aortobifemoral bypass and LVAD implantation in a patient with ischemic cardiomyopathy, severe peripheral vascular disease, and multiple previous failed revascularization attempts."

Our news editors obtained a quote from the research from Duke University, "In this patient, we used the LVAD outflow to provide the inflow to the femoral artery bypass graft. This graft has remained patent at a 2-year follow-up, without claudication symptoms. Performing concomitant major vascular operations safely and successfully is feasible in patients with LVADs."
According to the news editors, the research concluded: "Quality of life after ventricular assist device placement can be limited by vascular disease, but it can be markedly improved after vascular surgical intervention."

The news editors report that additional information may be obtained by contacting M. Bishawi, Duke University, Medical Center, Dept. of Surg, Div Cardiothorac Surg, Durham, NC 27710, United States. Additional authors for this research include A.A. Shah, R.L. McCann and C.A. Milano.

---

**Immune System Diseases and Conditions - HIV/AIDS**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Immune System Diseases and Conditions - HIV/AIDS. According to news originating from Durham, North Carolina, by NewsRx correspondents, research stated, "HIV-1 is a retrovirus that integrates into host chromatin and can remain transcriptionally quiescent in a pool of immune cells. This characteristic enables HIV-1 to evade both host immune responses and antiretroviral drugs, leading to persistent infection."

Our news journalists obtained a quote from the research from Duke University, "Upon reactivation of proviral gene expression, HIV-1 envelope (HIV-1 Env) glycoproteins are expressed on the cell surface, transforming latently infected cells into targets for HIV-1 Env-specific monoclonal antibodies (mAbs), which can engage immune effector cells to kill productively infected CD4(+) T cells and thus limit the spread of progeny virus. Recent innovations in antibody engineering have resulted in novel immunotherapeutics such as bispecific dual-affinity re-targeting (DART) molecules and other bi- and trispecific antibody designs that can recognize HIV-1 Env and recruit cytotoxic effector cells to kill CD4(+) T cells latently infected with HIV-1."

According to the news editors, the research concluded: "Here, we review these immunotherapies, which are designed with the goal of curing HIV-1 infection."

For more information on this research see: Envelope-specific antibodies and

**Central Nervous System Diseases and Conditions -…**

**Researchers from Emory University Report Findings in Epilepsy (Mechanistic Insight into NMDA Receptor Dysregulation by Rare Variants in the GluN2A and GluN2B Agonist Binding Domains)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Central Nervous System Diseases and Conditions - Epilepsy. According to news reporting originating from Atlanta, Georgia, by NewsRx correspondents, research stated, "Epilepsy and intellectual disability are associated with rare variants in the GluN2A and GluN2B (encoded by GRIN2A and GRIN2B) subunits of the N-methyl-D-aspartate receptor (NMDAR), a ligand-gated ion channel with essential roles in brain development and function. By assessing genetic variation across GluN2 domains, we determined that the agonist binding domain, transmembrane domain, and the linker regions between these domains were particularly intolerant to functional variation."

Financial supporters for this research include Eunice Kennedy Shriver National Institute of Child Health & Human Development, National Center for Advancing Translational Sciences of the NIH, National Institute of Neurological Disorders and Stroke, Xiangya-Emory Medical Schools Visiting Student Program.

Our news editors obtained a quote from the research from Emory University, "Notably, the agonist binding domain of GluN2B exhibited significantly more variation intolerance than that of GluN2A. To understand the ramifications of missense variation in the agonist binding domain, we investigated the mechanisms by which 25 rare variants in the GluN2A and GluN2B agonist binding domains dysregulated NMDAR activity. When introduced into recombinant human NMDARs, these rare variants identified in individuals with neurologic disease had complex, and sometimes opposing, consequences on agonist binding, channel gating, receptor biogenesis, and forward trafficking. Our approach combined quantitative assessments of these effects to estimate the overall impact on synaptic and non-
synaptic NMDAR function. Interestingly, similar neurologic diseases were associated with both gain-and loss-of-function variants in the same gene. Most rare variants in GluN2A were associated with epilepsy, whereas GluN2B variants were associated with intellectual disability with or without seizures."

According to the news editors, the research concluded: "Finally, discerning the mechanisms underlying NMDAR dysregulation by these rare variants allowed investigations of pharmacologic strategies to correct NMDAR function."

For more information on this research see: Mechanistic Insight into NMDA Receptor Dysregulation by Rare Variants in the GluN2A and GluN2B Agonist Binding Domains. American Journal of Human Genetics, 2016;99(6):1261-1280. American Journal of Human Genetics can be contacted at: Cell Press, 600 Technology Square, 5TH Floor, Cambridge, MA 02139, USA. Myeloid Cells

Researchers from Emory University Report Recent Findings in Myeloid Cells (Novel Multifunctional Nanomatrix Reduces Inflammation in Dynamic Conditions in Vitro and Dilates Arteries ex Vivo)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Myeloid Cells have been presented. According to news reporting originating in Atlanta, Georgia, by NewsRx journalists, research stated, "Inflammatory responses play a critical role in tissue-implant interactions, often limiting current implant utility. This is particularly true for cardiovascular devices."

Financial supporters for this research include Howard Hughes Medical Institute, National Institute of Neurological Disorders and Stroke, National Institute of Diabetes and Digestive and Kidney Diseases, National Heart, Lung, and Blood Institute, National Institute of Biomedical Imaging and Bioengineering, University of Alabama at Birmingham, The American Diabetes Association Research Foundation, National Aeronautics and Space Administration, U.S. Department of Energy, National Science Foundation, U.S. Department of Agriculture, American Heart Association.

The news reporters obtained a quote from the research from Emory University, "Existing stent technology does little to avoid or mitigate inflammation or to influence the
vasomotion of the artery after implantation. We have developed a novel endothelium-mimicking nanomatrix composed of peptide amphiphiles that enhances endothelialization while decreasing both smooth muscle cell proliferation and platelet adhesion. Here, we evaluated whether the nanomatrix could prevent inflammatory responses under static and physiological flow conditions. We found that the nanomatrix reduced monocyte adhesion to endothelial cells and expression of monocyte inflammatory genes (TNF-α, MCP-1, IL-1β, and IL-6). Furthermore, the nitric-oxide releasing nanomatrix dramatically attenuated TNF-α-stimulated inflammatory responses as demonstrated by significantly reduced monocyte adhesion and inflammatory gene expression in both static and physiological flow conditions. These effects were abolished by addition of a nitric oxide scavenger. Finally, the nanomatrix stimulated vasodilation in intact rat mesenteric arterioles after constriction with phenylephrine, demonstrating the bioavailability and bioactivity of the nanomatrix, as well as exhibiting highly desired release kinetics.

According to the news reporters, the research concluded: "These results demonstrate the clinical potential of this nanomatrix by both preventing inflammatory responses and promoting vasodilation, critical improvements in stent and cardiovascular device technology."

Our news correspondents report that additional information may be obtained by contacting Y.S. Yoon, School of Medicine, Division of Cardiology, Emory University, Atlanta, Georgia 30322, United States. Additional authors for this research include J.B. Vines, P. Hwang, T. Kim, J.A. Kim, B.C. Brott, Y.S. Yoon and H.W Jun.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1021/acsami.6b00565. This DOI is a link to an online electronic document that is either free or for purchase.

Cardiovascular Research

Researchers from Erasmus University Detail Findings in Cardiovascular Research (Vitamin D and retinal microvascular damage The Rotterdam Study)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Cardiovascular Research is now available. According to news reporting originating from Rotterdam, Netherlands, by NewsRx correspondents, research stated, "Vitamin D has been linked to various cardiovascular risk factors including indices of large-vessel disease. However, it remains unclear whether vitamin D is also associated with microvascular damage."

Our news editors obtained a quote from the research from Erasmus University, "In a
community-dwelling population, we studied associations between vitamin D serum levels and retinal microvascular damage defined as retinopathy signs, narrower arterioles, and wider venules. From the population-based Rotterdam Study, we included 5675 participants (age ≥ 45 years) with vitamin D data and gradable retinal photographs. Serum levels of vitamin D were measured using an antibody-based assay. Retinal exudates, microaneurysms, cotton wool spots, and dot/blot hemorrhages were graded on fundus photographs by experienced graders in the whole sample; retinal vascular calibers, that is, arteriolar and venular diameters, were semiautomatically measured in a subsample (n = 2973). We examined the cross-sectional association between vitamin D and retinal microvascular damage using logistic and linear regression models, adjusting for age, sex, and cardiovascular risk factors. We found that persons with lower vitamin D levels were more likely to have retinopathy (adjusted odds ratio per standard deviation (SD) decrease of vitamin D = 1.30; 95% confidence interval (CI): = 1.12-1.49). Furthermore, lower vitamin D levels were associated with wider venular calibers (adjusted mean difference per SD decrease in vitamin D = 1.35; 95% CI = 0.64-2.06). This association was strongest among men (P for interaction = 0.023).

According to the news editors, the research concluded: "Lower levels of vitamin D are associated with retinal microvascular damage, suggesting that the link with cardiovascular risk may partly run through changes in the microvasculature."

For more information on this research see: Vitamin D and retinal microvascular damage The Rotterdam Study. *Medicine*, 2016;95(49):180-185. *Medicine* can be contacted at: Lippincott Williams & Wilkins, Two Commerce Sq, 2001 Market St, Philadelphia, PA 19103, USA. (Elsevier - www.elsevier.com; Medicine - www.journals.elsevier.com/medicine/)

The news editors report that additional information may be obtained by contacting M.K. Ikram, Erasmus University, Medical Center, Dept. of Neurol, Rotterdam, Netherlands. Additional authors for this research include M.A. Ikram, A. Hofman, P. de Jong, A.G. Uitterlinden, C.C.W. Klaver and M.K. Ikram.

Eye Diseases and Conditions - Exfoliation Syndrome

Researchers from Eskisehir Osmangazi University Report on Findings in Exfoliation Syndrome (Comparison of Rotational Thromboelastography Findings in Pseudoexfoliation Syndrome Patients and Healthy Controls)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Eye Diseases and Conditions - Exfoliation Syndrome have been published. According to news reporting originating in Eskisehir, Turkey, by NewsRx journalists, research stated, "Rotational thromboelastography (ROTEM) is a useful test for studying the characteristics of fibrin clot formation. As patients with pseudoexfoliation (PEX) have an increased risk for thrombotic events, clot-forming dysfunction may play a role."

The news reporters obtained a quote from the research from Eskisehir Osmangazi University, "The aim of this study is to compare ROTEM findings in PEX syndrome patients..."
with age-matched and sex-matched healthy controls. A total of 21 patients with PEX syndrome and 22 age-matched and sex-matched healthy controls were included. All study participants underwent detailed ophthalmologic and systemic medical examination, including blood pressure measurement, hemoglobin-hematocrit levels, platelet count, coagulation parameters including prothrombin time, activated partial thromboplastin time, fibrinogen levels, and D-dimer levels. Peripheral blood samples were collected and analyzed with ROTEM Coagulation Analyzer. The mean age of patients with PEX and controls was 66.58.3 and 65.9 +/- 9.5 years, respectively (P= 0.7). The 2 groups did not differ with respect to age, sex, hemoglobin, hematocrit, platelet numbers, prothrombin time, activated partial thromboplastin time, fibrinogen levels, D-dimer levels, and glucose levels. When extrinsic thromboelastometry results were analyzed, PEX patients showed a significantly decreased clotting time when compared with healthy controls (79.8 vs. 98.0 s; P=0.01), indicating faster clot formation. Other ROTEM parameters did now show any difference between the 2 groups. PEX patients showed faster clotting time when compared with healthy controls. This fibrin clot formation dysfunction may lead to vascular thrombotic events in these patients."

According to the news reporters, the research concluded: "Further studies are needed to elucidate the exact underlying mechanism of thrombosis seen in PEX patients."

Our news correspondents report that additional information may be obtained by contacting D.G. Sahin, Eskisehir Osmangazi Univ, Sch Med, Dept. of Hematol, Eskisehir, Turkey. Additional authors for this research include A. Sahin and O.M. Akay.

Keywords for this news article include: Eskisehir, Turkey, Eurasia, Eye Diseases and Conditions, Exfoliation Syndrome, Prothrombin, Hematology, Eskisehir Osmangazi University.

Hematology - Blood Coagulation Factors

Researchers from Faculty of Medicine Detail Findings in Blood Coagulation Factors (Homozgyosity for a factor XII mutation in one female and one male patient with hereditary angio-oedema)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Hematology - Blood Coagulation Factors. According to news reporting out of Santo Andre, Brazil, by NewsRx editors, research stated, "Hereditary angio-oedema (HAE) with normal C1 inhibitor is associated with heterozygous mutations in the factor XII gene (FXII-HAE). We report two Brazilian FXII-HAE families segregating the mutation c.983 C>A (p.Thr328Lys)."

Financial supporters for this research include Fundacao de Amparo a Pesquisa do Estado de Sao Paulo, Sao Paulo State Research Foundation, ERA-Net E-RARE-1 research programme.
Our news journalists obtained a quote from the research from the Faculty of Medicine, "In each family, one patient with a homozygous mutation was found. The homozygous female patient in family 1 displayed a severe phenotype. However, this falls within the clinical phenotype spectrum reported for heterozygous female mutation carriers. The homozygous male patient in family 2 also showed a severe phenotype. This finding is intriguing, as to our knowledge, it is the first such report for a male FXII-HAE mutation carrier. In the rare instances in which male mutation carriers are affected, a mild phenotype is typical."

According to the news editors, the research concluded: "The present findings therefore suggest that homozygous FXII-HAE mutation status leads to a severe phenotype in females and males, and to an increased risk of manifest symptoms in the latter."

Our news journalists report that additional information may be obtained by contacting A.S. Grumach, Outpatient Group of Recurrent Infections and Laboratory of Clinical Immunology, Faculty of Medicine ABC, Santo Andre, Brazil. Additional authors for this research include C. Stieber, C.L. Veronez, N. Cagini, R.N. Constantino-Silva, E. Cordeiro, M.M. Nothen, J.B. Pesquero and S. Cichon.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1111/all.12769. This DOI is a link to an online electronic document that is either free or for purchase.

Drugs and Therapies - Disulfiram Therapy

Researchers from Faculty of Pharmacy Report Findings in Disulfiram Therapy (An Ophthalmic Formulation of Disulfiram Nanoparticles Prolongs Drug Residence Time in Lens)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Drugs and Therapies - Disulfiram Therapy is now available. According to news reporting out of Higashiosaka, Japan, by NewsRx editors, research stated, "Disulfiram (DSF) is a dimer of diethyldithiocarbamate (DDC) that we previously added to a solution of 2-hydroxypropyl-beta-cyclodextrin (DSF solution). We found that the instillation of this DSF solution delayed lens opacification in a hereditary cataractous ICR/f rat."

Our news journalists obtained a quote from the research from the Faculty of Pharmacy, "In this study, we attempted to design an ophthalmic formulation containing DSF nanoparticles for use as a lens targeted drug delivery system (nano-DSF suspension), and investigated the changes in drug content in the lens after the instillation of DSF solution or nanoDSF suspension. The nano-DSF suspension was prepared by a bead mill method to yield a mean particle size of nano-DSF of 181 nm. Following the instillation of 1.4% DSF solution or the nano-DSF suspension, DDC was detected only in the aqueous humor and lens; in both, the area under the curve (AUC) and mean residence time (MRT) for the nano-DSF suspension were
higher than for the DSF solution. In addition, we found that the DDC residence time in the cortex and nucleus of the lens was higher than in the capsule-epithelium. Although DDC was not detected in the cortex and nucleus of lenses following the instillation of the 1.4% DSF solution, the instillation of a 1.4% nano-DSF suspension led to the accumulation of DDC in both areas.

According to the news editors, the research concluded: "It is possible that the instillation of a nano-DSF suspension can supply more DDC into the aqueous humor and lens than a conventional formulation, and these findings provide information significant for the prevention of cataracts and the design of a lens targeted drug delivery system."

Our news journalists report that additional information may be obtained by contacting N. Nagai, Kindai Univ, Fac Pharm, Higashiosaka, Osaka 5778502, Japan. Additional authors for this research include Y. Mano and Y. Ito.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1248/bpb.b16-00592. This DOI is a link to an online electronic document that is either free or for purchase.

Angiogenesis

Researchers from Federal University Describe Findings in Angiogenesis (Chemopreventive effect and angiogenic activity of punicalagin isolated from leaves of Lafoensia pacari A. St.-Hil)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Angiogenesis have been published. According to news reporting out of Goiania, Brazil, by NewsRx editors, research stated, "Punicalagin is the major ellagittannin constituent from leaves of Lafoensia pacari, a Brazilian medicinal plant widely used for the treatment of peptic ulcer and wound healing. Genotoxic, cytotoxic, antigenotoxic, and anticytotoxic effects of punicalagin were assessed using micronucleus (MN) test and comet assay in mice."

Our news journalists obtained a quote from the research from Federal University, "Due to the extensive use of L. pacari in the wound healing process, we also assessed the angiogenic activity of punicalagin using the chick chorioallantoic membrane (CAM) angiogenic assay. The highest dose of punicalagin (50 mg/kg) showed significant cytotoxic effect by MN test and in the co-treatment with cyclophosphamide (CPA), this cytotoxicity was enhanced. Co-treatment, pre-treatment and post-treatment of punicalagin with CPA led to a significant reduction in the number of DNA breaks and in the frequency of CPA-induced MN, indicating
antigenotoxic effect. Using the CAM model, punicalagin exhibited angiogenic activity in all
doses mainly at the lowest concentration (12.5 g/L). Therefore, these findings indicate an
effective chemopreventive role of punicalagin and a high capacity to induce DNA repair."

According to the news editors, the research concluded: "Also, the angiogenic activity
presented by punicalagin in this study could contribute for the processes of tissue repairing and
wound healing."

For more information on this research see: Chemopreventive effect and angiogenic
activity of punicalagin isolated from leaves of Lafaonia pacari A. St.-Hil. Toxicology and
Applied Pharmacology, 2016;310():1-8. Toxicology and Applied Pharmacology can be

Oncology - Osteosarcomas

Researchers from Federal University Detail Findings in Osteosarcomas
(MAPK7 Gene Controls Proliferation, Migration and Cell Invasion in
Osteosarcoma)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness
& Wellness Week -- Research findings on Oncology - Osteosarcomas are discussed in a new
report. According to news reporting out of Sao Paulo, Brazil, by NewsRx editors, research
stated, "Osteosarcomas (OS) are the most common malignant bone tumors, and the
identification of useful tumor biomarkers and target proteins is required to predict the clinical
outcome of patients and therapeutic response as well as to develop novel therapeutic strategies.
In our previous study, MAPK7 has been identified as a candidate oncogene, and a promising
prognostic marker for OS."

Our news journalists obtained a quote from the research from Federal University,
"Sequential activation of protein kinases within the mitogen-activated protein kinase (MAPK)
cascades is a common mechanism of signal transduction in many cellular processes. In this
study, we investigated the behavior of MAPK7 gene in OS cell lines. Technical viability,
proliferation, migration, invasion, and apoptosis were used to evaluate the function of the
MAPK7 gene. We evaluated the behavior of the OS cells with MAPK7 gene silenced, not
silenced, and exposed to the main chemotherapy drugs used in OS treatment. We found that
silenced MAPK7 gene is effective at suppressing cell proliferation, inhibiting cell migration,
and invasion. Furthermore, MAPK7 is an important activator of transcription factors and is the
main expression modulator of other key genes in the MAPK pathway."

According to the news editors, the research concluded: "In summary, our study
suggests that MAPK7 might be a promising therapeutic target for OS."

Our news journalists report that additional information may be obtained by contacting S.R.C. Toledo, Federal University of Sao Paulo, Pediat Oncol Inst IOP GRAACC, Genet Lab, Dept. of Clin & Expt Oncol, Sao Paulo, SP, Brazil. Additional authors for this research include L.J.D. Lopes, A.S. Petrilli and S.R.C. Toledo.

Mental Health Diseases and Conditions - Affective...

**Researchers from Federal University Provide Details of New Studies and Findings in the Area of Affective Disorders (Liraglutide promotes improvements in objective measures of cognitive dysfunction in individuals with mood disorders: A pilot, ...)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Mental Health Diseases and Conditions - Affective Disorders. According to news reporting from Sao Paulo, Brazil, by NewsRx journalists, research stated, "There is a paucity of treatments that are capable of reliably and robustly improving cognitive function in adults with mood disorders. Glucagon-like peptide-1 is synthesized centrally and its receptors are abundantly expressed in neural circuits subserving cognitive function."

The news correspondents obtained a quote from the research from Federal University, "We aimed to determine the effects of liraglutide, a GLP-1 receptor (GLP-1 R) agonist, on objective measures of cognition in adults with a depressive or bipolar disorder. In this 4-week, pilot, open-label, domain-based study (e.g. cognition), we recruited 19 individuals with major depressive disorder (MDD) or bipolar disorder (BD) and an impairment in executive function. defined as a below-average performance in the Trail Making Test-B (TMTB). Liraglutide 1.8 mg/day was added as an adjunct to existing pharmacotherapy. Participants had significant increases from baseline to week 4 in the TMTB standard score (age am education corrected) (Cohen's d=0.64, p=0.009) and in a composite Z-score comprising multiple cognitive tests (i.e. Digit Symbol Substitution Test, Rey Auditory Verbal Learning Test, Stroop test) (Cohen's d=0.77, p< 0.001). Neither changes in mood rating scales nor metabolic parameters were associated with changes in cognitive performance (all p> 0.05); however baseline insulin resistance (IR) and body mass index (BMI; moderated the changes in the composite Z-score (p= 0.021 and p=0.046, respectively), indicating larger responses in individuals with higher IR and BMI at baseline. There was a significant increase in lipase (p < 0.001), but individual values were above the upper limit of normality. Limitations: Small sample size, open-label design, lack of a placebo group. Liraglutide was safe and well tolerated by a sample of non-diabetic individuals with mood disorders and had beneficial effects on objective measures of cognitive
According to the news reporters, the research concluded: "Larger studies with controlled trial designs are necessary to confirm and expand the results described herein."

For more information on this research see: Liraglutide promotes improvements in objective measures of cognitive dysfunction in individuals with mood disorders: A pilot, open-label study. *Journal of Affective Disorders*, 2017;207():114-120. *Journal of Affective Disorders* can be contacted at: Elsevier Science Bv, PO Box 211, 1000 Ae Amsterdam, Netherlands. **Researchers from Federal University Report on Findings in Obesity (No difference in acute effects of supplemental v. dietary calcium on blood pressure and microvascular function in obese women challenged with a high-fat meal: a cross-over ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Nutritional and Metabolic Diseases and Conditions - Obesity have been presented. According to news reporting out of Rio de Janeiro, Brazil, by NewsRx editors, research stated, "Recent studies suggest that supplemental Ca (SC) increases the risk of cardiovascular events, whereas dietary Ca (DC) decreases the risk of cardiovascular events. Although frequently consumed with meals, it remains unclear whether Ca can mitigate or aggravate the deleterious effects of a high-fat meal on cardiovascular risk factors."

Our news journalists obtained a quote from the research from Federal University, "This study aimed to evaluate the effects of SC or DC on blood pressure (BP) and microvascular function (MVF) in the postprandial period in obese women challenged with a high-fat meal. In this cross-over controlled trial, sixteen obese women aged 20-50 years were randomly assigned to receive three test meals (2908 kJ (695 kcal); 48% fat): high DC (HDCM; 547 mg DC), high SC (HSCM; 500 mg SC-calcium carbonate) and low Ca (LCM; 42mg DC). BP was continuously evaluated from 15 min before to 120 min after meals by digital photoplethysmography. Before and 120 min after meals, participants underwent evaluation of serum Ca and microvascular flow after postocclusive reactive hyperaemia (PORH) by laser speckle contrast imaging. Ionised serum Ca rose significantly only after HSCM. Systolic BP..."
increased after the three meals, whereas diastolic BP increased after LCM and HDCM. Hyperaemia peak, hyperaemia amplitude and AUC evaluated after PORH decreased with LCM. After HDCM, there was a reduction in hyperaemia peak and hyperaemia amplitude, whereas HSCM decreased only hyperaemia peak. However, comparative analyses of the effects of three test meals on serum Ca, BP and MVF revealed no significant meal x time interaction."

According to the news editors, the research concluded: "This study suggests that in obese women SC and DC do not interfere with the effects of a high-fat meal on BP and MVF."

Our news journalists report that additional information may be obtained by contacting M. Klein, Federal University of Rio de Janeiro, Inst Nutr, Dept. of Appl Nutr, Rio De Janeiro, Brazil. Additional authors for this research include P.M. Leal, V.P. Antunes, A.F. Sanjuliani and M. Klein.

Digestive System Diseases and Conditions - Acid Reflux Disease (Proton Pump Inhibitor Therapy for the Treatment of Laryngopharyngeal Reflux: A Meta-Analysis of Randomized Controlled Trials)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Digestive System Diseases and Conditions - Acid Reflux Disease are discussed in a new report. According to news originating from Luoyang, People's Republic of China, by NewsRx correspondents, research stated, "To compare the treatment effect of proton pump inhibitor (PPI) therapy and placebo for patients with laryngopharyngeal reflux (LPR). PubMed, Cochrane Library, and EMBASE were searched from the date of conception to August 2014."

Our news journalists obtained a quote from the research from First Affiliated Hospital, "Randomized controlled clinical trials (RCTs) were included in this meta-analysis if they compared the treatment response of PPI therapy and placebo among patients with LPR. The risk difference, the standard mean difference (SMD), and their corresponding 95% confidence intervals (CIs) were calculated for the endpoints evaluated. Fourteen eligible RCTs with 771 participants were identified and analyzed in this meta-analysis. By pooling all eligible data, we found that patients treated with PPI therapy had a significantly higher response rate than those who received placebo (risk difference=0.15; 95% CI, 0.01-0.30). Compared with placebo, PPI therapy could also improve the total reflux symptom index significantly (SMD=1.65; 95% CI,
0.15-3.14), but results of the reflux symptom index varied for specific symptoms. However, PPI therapy did not show any advantage over placebo in the improvement of the reflux finding score (SMD=0.62; 95% CI, -0.96-2.19)."

According to the news editors, the research concluded: "In this meta-analysis of 14 eligible RCTs, we found that in patients with LPR, PPI therapy could improve reflux symptoms significantly compared with placebo."

The news correspondents report that additional information may be obtained from H. Guo, Dept. of Gastroenterology, First Affiliated Hospital to Science and Technology University of Henan, Luoyang, Henan, People's Republic of China. Additional authors for this research include H. Ma and J. Wang.

Carboxylic Acids

**Researchers from Food and Drug Administration Report Findings in Carboxylic Acids (Extraction and Liquid Chromatography-Tandem Mass Spectrometry Detection of 3-Monochloropropanediol Esters and Glycidyl Esters in Infant Formula)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Carboxylic Acids is the subject of a report. According to news reporting originating from College Park, Maryland, by NewsRx correspondents, research stated, "A method was developed for the extraction of fatty acid esters of 3-chloro-1,2-propanediol (3-MCPD) and glycidol from infant formula, followed by quantitative analysis of the extracts using liquid chromatography tandem mass spectrometry (LC-MS/MS). These process-induced chemical contaminants are found in refined vegetable oils, and studies have shown that they are potentially carcinogenic and/or genotoxic, making their presence in edible oils (and processed foods containing these oils) a potential health risk."

Our news editors obtained a quote from the research from Food and Drug Administration, "The extraction procedure involves a liquid liquid extraction, where powdered infant formula is dissolved in water and extracted with ethyl acetate. Following shaking, centrifugation, and drying of the organic phase, the resulting fat extract is cleaned-up using solid-phase extraction and analyzed by LC-MS/MS. Method performance was confirmed by verifying the percent recovery of each 3-MCPD and glycidyl ester in a homemade powdered
According to the news editors, the research concluded: "Based on the validation results, this method is suitable for producing 3-MCPD and glycidyl ester occurrence data in all commercially available varieties of infant formula."

The news editors report that additional information may be obtained by contacting J.K. Leigh, Food & Drug Administration, Center Food Safety & Appl Nutr, College Park, MD 20740, United States.

**Oncology - Colon Cancer**

**Researchers from Fourth Military Medical University Describe Findings in Colon Cancer (High expression of CREPT promotes tumor growth and is correlated with poor prognosis in colorectal cancer)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Oncology - Colon Cancer. According to news originating from Xi'an, People's Republic of China, by NewsRx correspondents, research stated, "CREPT (cell cycle-related and expression elevated protein in tumor) is highly expressed in many kinds of cancer, and has been shown to be prognostic in certain cancers. However, the clinical significance of CREPT in colorectal cancer (CRC) has not been sufficiently investigated."

Financial support for this research came from National Natural Sciences Foundation of China.

Our news journalists obtained a quote from the research from Fourth Military Medical University, "In this study, we examined the CREPT expression in 225 clinical CRC tissues and paired adjacent normal tissues, and analyzed the correlation between CREPT expression and other clinicopathological features. We also evaluated the biological function of CREPT both in vitro and in vivo using knockdown or overexpressing CRC cells. Our results showed that CREPT expressed in 175 of 225 (77.8%) CRC patients and the CREPT expression was significantly associated with tumor differentiation (P = 0.000), Dukes' stages (P = 0.013) and metastasis (P = 0.038). Patients with high CREPT expression tended to have shorter survival time. Multivariate analysis showed that positive CREPT expression can be used as an
independent predictor for CRC prognosis. CREPT knockdown cells showed inhibited cell proliferation and arrested cell cycle, while CREPT overexpressing cells showed increased proliferation and promoted cell cycle. In addition, CREPT overexpression significantly promoted tumor growth in vivo."

According to the news editors, the research concluded: "Mechanism study showed that CREPT may regulate cell proliferation and cell cycle through the regulation on cyclin D3, CDK4 and CDK6."

For more information on this research see: High expression of CREPT promotes tumor growth and is correlated with poor prognosis in colorectal cancer. *Biochemical and Biophysical Research Communications*, 2016;480(3):436-442. *Biochemical and Biophysical Research Communications* can be contacted at: Academic Press Inc Elsevier Science, 525 B St, Ste 1900, San Diego, CA 92101-4495, USA. **Oncology**

**Researchers from Fourth Military Medical University Report Findings in Oncology (ALK and ROS1 as targeted therapy paradigms and clinical implications to overcome crizotinib resistance)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Oncology. According to news reporting originating in Xi'an, People's Republic of China, by NewsRx journalists, research stated, "During the past decade, more than 10 targetable oncogenic driver genes have been validated in non-small cell lung cancer (NSCLC). Anaplastic lymphoma kinase (ALK) and ROS1 kinase are two new driver genes implicated in ALK-and ROS1-rearranged NSCLC."

The news reporters obtained a quote from the research from Fourth Military Medical University. "Inhibition of ALK and ROS1 by crizotinib has been reported to be highly effective and well tolerated in these patients. However, resistance to crizotinib emerges years after treatment, and increasing efforts have been made to overcome this issue. Here, we review the biology of ALK and ROS1 and their roles in cancer progression. We also summarize the ongoing and completed clinical trials validating ALK and ROS1 as targets for cancer treatment. In the last section of the review, we will discuss the molecular mechanisms of crizotinib resistance and focus approaches to overcome it."
According to the news reporters, the research concluded: "This review describes an exciting new area of research and may provide new insights for targeted cancer therapies."

For more information on this research see: ALK and ROS1 as targeted therapy paradigms and clinical implications to overcome crizotinib resistance. Oncotarget, 2016;7(11):12289-304.

Our news correspondents report that additional information may be obtained by contacting M. Ye, Dept. of Pulmonary Medicine, Xijing Hospital, Fourth Military Medical University, Xi'an, People's Republic of China. Additional authors for this research include X. Zhang, N. Li, Y. Zhang, P. Jing, N. Chang, J. Wu, X. Ren and J. Zhang.

Oncology - Non-Small Cell Lung Cancer

Researchers from Free University Describe Findings in Non-Small Cell Lung Cancer (Utilising the EGFR interactome to identify mechanisms of drug resistance in non-small cell lung cancer - Proof of concept towards a systems pharmacology approach)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Oncology - Non-Small Cell Lung Cancer is the subject of a report. According to news reporting from Berlin, Germany, by NewsRx journalists, research stated, "Drug treatment of epidermal growth factor receptor (EGFR) positive non-small cell lung cancer has improved substantially by targeting activating mutations within the receptor tyrosine kinase domain. However, the development of drug resistance still limits this approach."

The news correspondents obtained a quote from the research from Free University, "As root causes, large heterogeneity between tumour entities but also within tumour cells have been suggested. Therefore, approaches to identify these multitude and complex mechanisms are urgently required. Affinity purification coupled with high resolution mass spectrometry was applied to isolate and characterise the EGFR interactome from HCC4006 non-small cell lung cancer cells and their variant HCC4006(r)ERLO(0.5) adapted to grow in the presence of therapeutically relevant concentrations of erlotinib. Bioinformatics analyses were carried out to identify proteins and their related molecular functions that interact differentially with EGFR in the untreated state or when incubated with erlotinib prior to EGFR activation. Across all experimental conditions 375 proteins were detected to participate in the EGFR interactome, 90% of which constituted a complex protein interaction network that was bioinformatically reconstructed from literature data. Treatment of HCC4006(r)ERLO(0.5) cells carrying a resistance phenotype to erlotinib was associated with an increase of protein levels of members of the clathrin-associated adaptor protein family AP2 (AP2A1, AP2A2, AP2B1), structural proteins of cytoskeleton rearrangement as well as signalling molecules such as Shc. Validation experiments confirmed activation of the Ras-Raf-Mek-Erk (MAPK)-pathway, of which Shc is an initiating adaptor molecule, in HCC4006(r)ERLO(0.5) cells. Taken together, differential
proteins in the EGFR interactome of HCC4006(r)ERLO(0.5) cells were identified that could be related to multiple resistance mechanisms including alterations in growth factor receptor expression, cellular remodelling processes suggesting epithelial-to-mesenchymal transition as well as alterations in downstream signalling.

According to the news reporters, the research concluded: "Knowledge of these mechanisms is a pivotal step to build an integrative model of drug resistance in a systems pharmacology manner and to be able to investigate the interplay of these mechanisms and ultimately recommend combinatorial treatment strategies to overcome drug resistance."

DNA Research

Researchers from Free University Discuss Findings in DNA Research (Engineering biodegradable micelles of polyethylenimine-based amphiphilic block copolymers for efficient DNA and siRNA delivery)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on DNA Research is the subject of a report. According to news reporting out of Berlin, Germany, by NewsRx editors, research stated, "Polycationic micelles have shown advantageous properties as nucleic acid delivery vectors both in vitro and in vivo. In contrast to polycationic micelles reported so far, we designed particles integrating a sufficient nucleic acid condensation capability by polycationic polyethylenimine (PEI) segments as well as only a mild cytotoxic behavior."

Funders for this research include German Research Foundation, Helmholtz Association, Federal Ministry of Education and Research, Germany.

Our news journalists obtained a quote from the research from Free University, "The micelles composed of a hydrophobic oligoester core with glycolide units resulting in fast
degradation after cellular internalization in combination with PEG moieties acting as shielding agents. By grafting branched 25 kDa polyethylenimine (PEI25) and poly(ethylene glycol) (PEG) on poly[(ε-caprolactone)-co-glycolide] (CG), amphiphilic PEI-CG-PEI and PEG-CG block copolymers were used to form a series of micelles via self-assembly of PEI-CG-PEI or co-assembly of both copolymers for DNA and siRNA delivery. This modular system enabled a systematic investigation of different parameters and their synergetic effects as different functions were introduced. The polyplex formation and serum stability, cytotoxicity, and transfection activity could be tailored by changing the CG chain length in PEI-based copolymer, incorporating PEG-CG, and varying the N/P ratio. All micelle-based polyplex compositions showed high DNA transfection activity according to reporter gene-expression and an exceptionally high knockdown in siRNA delivery experiments. Remarkably, the GFP expression of >99% cells was successfully knocked down by micelle-mediated siRNA interference, resulting in a decrease of two orders of magnitude in fluorescence intensity. Incorporation of PEG-CG in the micelles reduced the PEI-related cytotoxicity, and markedly enhanced the serum stability of both DNA and siRNA polyplexes. Compared with homo-PEI25, these micelles showed several advantages including the lower toxicity, higher siRNA transfection efficiency and higher polyplex stability in the presence of serum.

According to the news editors, the research concluded: "This study therefore provides an effective approach to tune the structure, property and function of polycationic micelles for efficient DNA and siRNA delivery, which could contribute to the design and development of novel non-viral transfection vectors with superb functionality."

For more information on this research see: Engineering biodegradable micelles of polyethylenimine-based amphiphilic block copolymers for efficient DNA and siRNA delivery. Journal of Controlled Release, 2016;242():71-79. Journal of Controlled Release can be contacted at: Elsevier Science Bv, PO Box 211, 1000 Ae Amsterdam, Netherlands. (Elsevier - www.elsevier.com; Journal of Controlled Release - www.journals.elsevier.com/journal-of-controlled-release/)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Oncology - Breast Cancer. According to news reporting originating in Paris, France, by NewsRx journalists, research stated, "Trastuzumab was introduced a decade ago and has improved outcomes for HER2-positive breast cancer. We investigated the factors predictive of pathological complete response (pCR), prognostic factors for disease-free survival (DFS), and interactions between pCR and DFS after neoadjuvant treatment."

The news reporters obtained a quote from the research from the French National Institute of Health and Medical Research (INSERM), "We identified 287 patients with primary HER2-positive breast cancers given neoadjuvant chemotherapy (NAC) between 2002 and 2011. Univariate and multivariate analyses of clinical and pathological factors associated with pCR and DFS were performed. pCR rates differed between patients receiving neoadjuvant trastuzumab treatment or not (47.7% versus 19.3%, p<0.0001). DFS also differed significantly between patients receiving adjuvant trastuzumab or not (hazard ratio=4.84, 95% CI (2.52; 9.31), p<0.001). We analysed 199 patients given neoadjuvant and adjuvant trastuzumab. Multivariate analysis identified older age and hormone receptor-negative tumours as independent predictors of pCR. T stage (hazard ratio=2.55, 95% CI (1.01; 6.48), p=0.05) and strict pCR (hazard ratio=9.15, 95% CI (1.22; 68.83), p=0.03) were independent predictors of DFS. The latter association was significant in the HR-negative subgroup (p=0.02) but not in the HR-positive subgroup (p=0.12). Major pCR and DFS gains in HER2-positive BC were observed since 'trastuzumab' era."

According to the news reporters, the research concluded: "Further improvements rely on the enrollment of accurately selected patients into clinical trials."

For more information on this research see: Pathological complete response and prognosis after neoadjuvant chemotherapy for HER2-positive breast cancers before and after trastuzumab era: results from a real-life cohort. British Journal of Cancer, 2015;114(1):44-52. (Nature Publishing Group - www.nature.com/; British Journal of Cancer - www.nature.com/bjc/)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Liver Diseases and Conditions - Hepatitis B Virus are presented in a new report. According to news reporting originating from Paris, France, by NewsRx correspondents, research stated, "In Sub-Saharan Africa, seroclearance of hepatitis B surface antigen (HBsAg) and hepatitis B ‘e’ antigen (HBeAg), including their quantifiable markers, have rarely been evaluated during long-term antiviral treatment among patients coinfected with HIV and hepatitis B virus (HBV). In this prospective cohort study from two randomized-control trials in Côte d'Ivoire, 161 antiretroviral-naïve HIV-HBV coinfected patients starting lamivudine (n=76) or tenofovir/emtricitabine (n=85) containing antiretroviral therapy were included."

Funders for this research include Agence Nationale de Recherche sur le Sida et les Hepatites, ANRS.

Our news editors obtained a quote from the research from the French National Institute of Health and Medical Research (INSERM), "HBV DNA was quantified using an in-house assay (detection limit=12 copies/mL) and HBsAg quantification (qHBsAg) using the Elecsys assay. Overall, 33 (20.5%) patients were HBeAg positive, 121 (75.2%) had detectable HBV DNA, and 92/93 (98.9%) harbored HBV genotype E. Median treatment duration was 35.5 months (interquartile range: 24.3-36.4). Among HBeAg-positive patients, cumulative proportion with HBeAg seroclearance was 46.3% (n=14). Overall, cumulative proportion of HBsAg seroclearance was 6.6% (n=10). Lower baseline qHBsAg levels and strong 12-month declines in qHBsAg were significantly associated with HBsAg seroclearance for both HBeAg-negative and HBeAg-positive patients. When taken at certain levels, these determinants provided moderate sensitivity (Se) and specificity (Sp) in predicting HBsAg seroclearance at month 36 ( (<=) 1000 IU/mL at baseline, Se=0.80, Sp=0.80; (>=) 1.0 log10 IU/mL at month 12, Se=0.57, Sp=1.00). Instead, qHBsAg levels (<=) 100 or (<=) 10 IU/mL at month 12 were optimal (both Se=0.90 and Sp=1.00). Detectable HBV-DNA provided fairly high Se and Sp when evaluated at baseline (Se=1.00, Sp=0.80), but not at month 12 (Se=0.80, Sp=0.40)."

According to the news editors, the research concluded: "HBsAg seroclearance rates are not common in patients from Sub-Saharan Africa treated with anti-HBV containing antiretroviral therapy. qHBsAg levels at 12 months of treatment may accurately predict HBsAg seroclearance."

The news editors report that additional information may be obtained by contacting A. Boyd, INSERM, UMR_S1136, Institut Pierre Louis d'Epidemiologie et de Sante Publique, Paris, France. Researchers from Fudan University Describe Findings in Hypertension (Short sleep duration is associated with increased risk of pre-hypertension and hypertension in Chinese early middle-aged females)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Cardiovascular Diseases and Conditions - Hypertension are presented in a new report. According to news reporting originating in Shanghai, People's Republic of China, by NewsRx journalists, research stated, "The aim of this study is to investigate the relationship between sleep duration and hypertension in a middle-aged Chinese population. Cross-sectional data of 20,505 individuals aged 35-64 years from Taizhou longitudinal study was used."

Financial supporters for this research include International cooperation project of Ministry of Science and Technology, The National Basic Research Program, National Natural Science Foundation of China.

The news reporters obtained a quote from the research from Fudan University, "Logistic regression models were used to calculate odds ratios (ORs) for the risk of pre-hypertension and hypertension in association with sleep duration. Short sleep duration was associated with high systolic and diastolic blood pressure in comparison with sleep duration of 7-8 h in females. Short sleep duration was also associated with an increased risk of hypertension in females. Age-stratified analysis showed that as compared with sleep duration of 7-8 h, sleep duration < 6 h increased risk of hypertension after controlling for multiple covariates with an OR of 1.766 (1.024-2.775) in early middle-aged females of 35-44 years. More importantly, sleeping less than 6 h is associated with increased risk of pre-hypertension in females of this age category, after controlling for multiple covariates with an OR of 1.769 (1.058-2.958). Sleeping less than 6 h a day is associated with increased risk of pre-hypertension and hypertension in Chinese early middle-aged females."

According to the news reporters, the research concluded: "The high-risk populations require sufficient sleep, which could probably prevent the increased risk of pre-hypertension as well as hypertension."

For more information on this research see: Short sleep duration is associated with increased risk of pre-hypertension and hypertension in Chinese early middle-aged females. *Sleep and Breathing*, 2016;20(4):1355-1362. *Sleep and Breathing* can be contacted at: Springer Heidelberg, Tiergartenstrasse 17, D-69121 Heidelberg, Germany. Researchers from Fudan University Report Recent Findings in Osteonecrosis (Involvement of MicroRNA-210 Demethylation in Steroid-associated Osteonecrosis of the Femoral Head)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Musculoskeletal Diseases and Conditions - Osteonecrosis. According to news originating from Shanghai, People's Republic of China, by NewsRx correspondents, research stated, "Angiogenesis is an important event in steroid-associated osteonecrosis of the femoral head (SONFH). Here we performed miRNA microarray with SONFH tissues (ONs) and the adjacent normal tissues (NLs) to select the angiogenic miRNA."

Our news journalists obtained a quote from the research from Fudan University, "The results showed that miR-210 was differentially expressed in SONFH versus normal tissues. Unexpectedly, its specific transcription factor, hypoxia-inducible factor-1a, was shown of no significant changes in ONs compared with NLs. Further Bisulfite sequencing revealed that miR-210 is embedded in a CpG island and miR-210 gene has 2 CpG sites with lower methylation percentage in ONs compared with NLs. Additionally, ONs with lower miR-210 gene methylation exhibited higher miR-210 expression. Next, we found that the endothelial cells treated with demethylating agents could significantly increase the expression of miR-210, along with promoted cell viability and differentiation. Some angiogenic genes (VEGF, bFGF, TNF-a and PCNA) were up-regulated as well. In addition, the supernatant of the cells after demethylation treatment displayed an enhanced ability of recruiting new microvessels in vivo."

According to the news editors, the research concluded: "Taken together, our study not only provides novel insights into the regulation of angiogenesis in this disease, but also reveals a therapeutic opportunity for treatment of SONFH patients with demethylating agents."

For more information on this research see: Involvement of MicroRNA-210 Demethylation in Steroid-associated Osteonecrosis of the Femoral Head. Scientific Reports, 2016;6():20046. (Nature Publishing Group - www.nature.com/; Scientific Reports - www.nature.com/srep/)

The news correspondents report that additional information may be obtained from H.F. Yuan, Dept. of Orthopedics, Zhongshan Hospital, Fudan University, Shanghai, People's Republic of China. Additional authors for this research include V.R. Christina, C.A. Guo, Y.W. Chu, R.H. Liu and Z.Q Yan.

Researchers from Fujian Medical University Provide Details of New Studies and Findings in the Area of Antineoplastics (The mitochondrion interfering compound NPC-26 exerts potent anti-pancreatic cancer cell activity in vitro and in vivo)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Drugs and Therapies - Antineoplastics is now available. According to news reporting originating in Quanzhou, People's Republic of China, by NewsRx journalists, research stated, "The development of novel anti-pancreatic cancer agents is extremely important. Here, we investigated the anti-pancreatic cancer activity by NPC-26, a novel mitochondrion interfering compound."

The news reporters obtained a quote from the research from Fujian Medical University, "We showed that NPC-26 was anti-proliferative and cytotoxic to human pancreatic cancer cells, possibly via inducing caspase-9-dependent cell apoptosis. Pharmacological inhibition or shRNA-mediated silence of caspase-9 attenuated NPC-26-induced pancreatic cancer cell death and apoptosis. Further, NPC-26 treatment led to mitochondrial permeability transition pore (mPTP) opening in the cancer cells, which was evidenced by mitochondrial depolarization, ANT-1(adenine nucleotide translocator-1)-Cyp-D (cyclophilin-D) association and oxidative phosphorylation disturbance. mPTP blockers (cyclosporin and sanglifehrin A) or shRNA-mediated knockdown of key mPTP components (Cyp-D and ANT-1) dramatically attenuated NPC-26-induced pancreatic cancer cell apoptosis. In vivo, NPC-26 intraperitoneal injection significantly suppressed the growth of PANC-1 xenograft tumors in nude mice. Meanwhile, NPC-26 sensitized gemcitabine-mediated anti-pancreatic cancer activity in vivo."

According to the news reporters, the research concluded: "In summary, the results of this study suggest that NPC-26, alone or together with gemcitabine, potently inhibits pancreatic cancer cells possibly via disrupting mitochondrion."

For more information on this research see: The mitochondrion interfering compound NPC-26 exerts potent anti-pancreatic cancer cell activity in vitro and in vivo. Tumor Biology, 2016;37(11):15053-15063. Tumor Biology can be contacted at: Springer, Van Godewijckstraat 30, 3311 Gz Dordrecht, Netherlands. Researchers from Gazes Cardiac Research Institute Report Recent Findings in Cardiology (Dasatinib Attenuates Pressure Overload Induced Cardiac Fibrosis in a Murine Transverse Aortic Constriction Model)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Cardiology. According to news reporting originating from Charleston, South Carolina, by NewsRx correspondents, research stated, "Reactive cardiac fibrosis resulting from chronic pressure overload (PO) compromises ventricular function and contributes to congestive heart failure. We explored whether nonreceptor tyrosine kinases (NTKs) play a key role in fibrosis by activating cardiac fibroblasts (CFb), and could potentially serve as a target to reduce PO-induced cardiac fibrosis."

Our news editors obtained a quote from the research from Gazes Cardiac Research Institute, "Our studies were carried out in PO mouse myocardium induced by transverse aortic constriction (TAC). Administration of a tyrosine kinase inhibitor, dasatinib, via an intraperitoneally implanted mini-osmotic pump at 0.44 mg/kg/day reduced PO-induced accumulation of extracellular matrix (ECM) proteins and improved left ventricular geometry and function. Furthermore, dasatinib treatment inhibited NTK activation (primarily Pyk2 and Fak) and reduced the level of FSP1 positive cells in the PO myocardium. In vitro studies using cultured mouse CFb showed that dasatinib treatment at 50 nM reduced: (i) extracellular accumulation of both collagen and fibronectin, (ii) both basal and PDGF-stimulated activation of Pyk2, (iii) nuclear accumulation of Ki67, SKP2 and histone-H2B and (iv) PDGF-stimulated CFb proliferation and migration. However, dasatinib did not affect cardiomyocyte morphologies in either the ventricular tissue after in vivo administration or in isolated cells after in vitro treatment. Mass spectrometric quantification of dasatinib in cultured cells indicated that the uptake of dasatinib by CFb was greater that that taken up by cardiomyocytes. Dasatinib treatment primarily suppressed PDGF but not insulin-stimulated signaling (Erk versus Akt activation) in both CFb and cardiomyocytes."

According to the news editors, the research concluded: "These data indicate that dasatinib treatment at lower doses than that used in chemotherapy has the capacity to reduce hypertrophy-associated fibrosis and improve ventricular function."

For more information on this research see: Dasatinib Attenuates Pressure Overload Induced Cardiac Fibrosis in a Murine Transverse Aortic Constriction Model. Plos One, 2015;10 (10):e0140273. (Public Library of Science - www.plos.org; Plos One - www.plosone.org)

The news editors report that additional information may be obtained by contacting S. Researchers from General Hospital Discuss Findings in Cancer Risk (Unprovoked venous thromboembolism and subsequent cancer risk: a population-based cohort study)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Oncology - Cancer Risk. According to news reporting out of Kaohsiung, Taiwan, by NewsRx editors, research stated, "ESSENTIALS: A relationship between unprovoked venous thromboembolism (VTE) and cancer risk was investigated. We collected 27,751 VTE patients and compared them with 110,409 frequency-matched people without VTE."

Funders for this research include Taiwan Ministry of Health and Welfare Clinical Trial, Research Center of Excellence, China Medical University Hospital, Academia Sinica Taiwan Biobank, Stroke Biosignature Project, NRPB Stroke Clinical Trial Consortium, Tseng-Lien Lin Foundation, Taichung, Taiwan, Taiwan Brain Disease Foundation, Taipei, Taiwan, Katsuzo and Kiyo Aoshima Memorial Funds, Japan, China Medical University Hospital Cancer Research Center of Excellence.

Our news journalists obtained a quote from the research from General Hospital, "This cohort study showed significantly higher risks of overall and site-specific cancers in the VTE group. There is an increased risk in the first 6 months after VTE, and VTE can be an indicator of occult cancer. We investigated the relationship between unprovoked venous thromboembolism (VTE) and subsequent cancer risk in Taiwan, focusing on both short-term and long-term cancer development. For the case group, we obtained data on 27,751 patients diagnosed with unprovoked VTE between 1 January 1998, and 31 December 2008. For the comparison group, four people without unprovoked VTE were frequency-matched with each unprovoked VTE patient according to age, sex, and index year. Cox proportional hazards regression models were employed to determine the effects of unprovoked VTE on cancer risk. Overall cancer risk was significantly higher in the unprovoked VTE group than in the comparison group (adjusted hazard ratio=2.26, 95% confidence interval=2.16-2.37). The increased risk was observed in both men and women in various age groups. The patients in the unprovoked VTE group showed a significantly increased risk of cancer at all site-specific cancer sites. Analyses stratified according to follow-up duration revealed that significant differences were more evident between the two groups over a follow-up duration of <0.5 years than over a follow-up duration of (>=) 3 years. Furthermore, the 1-year mortality risk of cancer patients with unprovoked VTE was significantly higher than that for cancer patients in the non-VTE group. The results of this study show that unprovoked VTE is associated with a consistently high risk of subsequent cancer diagnosis. This is particularly true in the first 6 months after VTE."

According to the news editors, the research concluded: "It suggests that unprovoked VTE can be an indicator of occult malignancy."

Our news journalists report that additional information may be obtained by contacting L.M. Sun, Dept. of Radiation Oncology, Zuoying Branch of Kaohsiung Armed Forces General Hospital, Kaohsiung, Taiwan. Additional authors for this research include W.S. Chung, C.L. Lin, J.A. Liang and C.H Kao.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1111/jth.13251. This DOI is a link to an online electronic document that is either free or for purchase.

**Oncology - Osteosarcomas**

**Researchers from General Hospital Report Recent Findings in Osteosarcomas (Effect of Unplanned Therapy on the Prognosis of Patients with Extremity Osteosarcoma)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Oncology - Osteosarcomas are presented in a new report. According to news originating from Jinan, People's Republic of China, by NewsRx correspondents, research stated, "Unplanned therapy for extremity osteosarcoma can result in erroneous surgical procedures and lack of neoadjuvant chemotherapy before the first operation. Our aim was to compare the prognosis between patients with extremity osteosarcoma who received unplanned therapy and those who received standard treatment."

Our news journalists obtained a quote from the research from General Hospital, "This was a retrospective review of patients with extremity osteosarcoma who received appropriate surgical treatment and neoadjuvant chemotherapy (n = 79) and those who received unplanned therapy (n = 24) between June 2000 and October 2014. Survival rate, local recurrence rate and metastasis rate were compared between the two groups. We found that patients who had unplanned therapy had a higher local recurrence rate (41.7% vs. 21.5%; P = 0.049) and a shorter mean time for recurrence (8.90 vs. 14.59 months; P = 0.018). There was no significant difference between groups in the 5-year survival rate (56.3% vs. 67.8%; P = 0.356), metastasis rate (45.8% vs. 30.4%; P = 0.125) and mean time to metastasis (23.18 vs. 18.24 months; P = 0.396). Our findings suggest that unplanned therapy for extremity osteosarcoma can result in failure of local control."

According to the news editors, the research concluded: "The use of supplementary interventions after unplanned therapy, such as neoadjuvant chemotherapy and limb salvage surgery, may explain the similar survival and metastasis rates between patients receiving unplanned therapy and those receiving standard treatment."

For more information on this research see: Effect of Unplanned Therapy on the Prognosis of Patients with Extremity Osteosarcoma. *Scientific Reports*, 2016;6():1-6.
Researchers from George Washington University Discuss Findings in Neurons (Direct Projections From Hypothalamic Orexin Neurons To Brainstem Cardiac Vagal Neurons)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Neurons. According to news reporting originating from Washington, District of Columbia, by NewsRx correspondents, research stated, "Orexin neurons are known to augment the sympathetic control of cardiovascular function, however the role of orexin neurons in parasympathetic cardiac regulation remains unclear. To test the hypothesis that orexin neurons contribute to parasympathetic control we selectively expressed channelrhodopsin-2 (ChR2) in orexin neurons in orexin-Cre transgenic rats and examined postsynaptic currents in cardiac vagal neurons (CVNs) in the dorsal motor nucleus of the vagus (DMV)."

Financial support for this research came from NIH.

Our news editors obtained a quote from the research from George Washington University, "Simultaneous photostimulation and recording in ChR2-expressing orexin neurons in the lateral hypothalamus resulted in reliable action potential firing as well as large whole-cell currents suggesting a strong expression of ChR2 and reliable optogenetic excitation. Photostimulation of ChR2-expressing fibers in the DMV elicited short-latency (ranging from 3.2 ms to 8.5 ms) postsynaptic currents in 16 out of 44 CVNs tested. These responses were heterogeneous and included excitatory glutamatergic (63%) and inhibitory GABAergic (37%) postsynaptic currents."

According to the news editors, the research concluded: "The results from this study suggest different sub-population of orexin neurons may exert diverse influences on brainstem CVNs and therefore may play distinct functional roles in parasympathetic control of the heart."

For more information on this research see: Direct Projections From Hypothalamic Orexin Neurons To Brainstem Cardiac Vagal Neurons. *Neuroscience*, 2016;339():47-53.

*Neuroscience* can be contacted at: Pergamon-Elsevier Science Ltd, The Boulevard, Langford Lane, Kidlington, Oxford OX5 1GB, England. (Elsevier - www.elsevier.com; Neuroscience - www.journals.elsevier.com/neuroscience/)

Researchers from Georgetown University Describe Findings in Pancreatic Cancer (Circulating microRNA profile predicts disease progression in patients receiving second-line treatment of lapatinib and capecitabine for metastatic pancreatic cancer)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Oncology - Pancreatic Cancer have been presented. According to news reporting out of Washington, District of Columbia, by NewsRx editors, research stated, "Patients exhibiting pancreatic cancer possess poor rates of survival. Therefore, the identification of a biomarker that can be measured non-invasively and be used to predict patient outcomes is required for the successful treatment of pancreatic cancer."

Our news journalists obtained a quote from the research from Georgetown University, "The present study evaluated serum microRNA (miRNA/miR) profiles in patients exhibiting pancreatic cancer, who were treated with lapatinib and capecitabine in a phase II trial. Serum samples were collected for the measurement of a panel of miRNAs (miR-21, miR-210, miR-221 and miR-7) associated with the epidermal growth factor receptor (EGFR)1 and human epidermal growth factor receptor (HER)2 pathways. Preclinically, human pancreatic cancer PANC-1, MIA PaCa-2 and BXPC-3 cell lines were utilized for miRNA and drug resistance studies. In total, 6/17 patients treated experienced disease progression following 2 cycles of treatment [non-responders (NRS)], while another 6/17 patients exhibited a stable disease state and received >4 cycles of treatment [responders (RS); range, 4-22 cycles]. Five patients withdrew from the study due to severe toxicity or mortality. The mean overall survival time was 6.5 vs. 10.4 months for NRS and RS, respectively. Significant upregulation of serum miRNAs at earlier time points (3-6 weeks) was observed in NRS. miRNA levels increased with cancer progression, and lapatinib and 5-fluorouracil (5-FU: the active form of capecitabine) treatment increased the miRNA levels (specifically miR-210 and miR-221) in the treatment-resistant pancreatic cancer PANC-1 and MIA PaCa-2 cell lines. However, lapatinib and 5-FU treatment did not increase the miRNA levels in the treatment-sensitive BXPC-3 cell line. Inhibition of miR-221 increased the sensitivity of the PANC-1 cells to treatment."

According to the news editors, the research concluded: "An increase in specific serum miRNAs was associated with resistance to lapatinib and capecitabine treatment. Additional investigation is required with regard to the application of the miRNA panel investigated in the present study as a potential predictor of patient responses to anti-EGFR/HER2 treatment."

For more information on this research see: Circulating microRNA profile predicts

**Nanotechnology**

**Researchers from Georgia Institute of Technology and Emory University Detail Findings in Nanotechnology** *(Cu-Doped PdCu@Au Tripods: A Multifunctional Nanomaterial for Positron Emission Tomography and Image-Guided Photothermal ...)*

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Nanotechnology have been presented. According to news reporting out of Atlanta, Georgia, by NewsRx editors, research stated, "This article reports a facile synthesis of radiolabeled PdCu@Au core-shell tripods for use in positron emission tomography (PET) and image-guided photothermal cancer treatment by directly incorporating radioactive (64)Cu atoms into the crystal lattice. The tripod had a unique morphology determined by the PdCu tripod that served as a template for the coating of Au shell, in addition to well-controlled specific activity and physical dimensions."

Funders for this research include National Cancer Institute, Georgia Institute of Technology, China Scholarship Council.

Our news journalists obtained a quote from the research from the Georgia Institute of Technology and Emory University, "The Au shell provided the nanostructure with strong absorption in the near-infrared region and effectively prevented the Cu and (64)Cu atoms in the core from oxidization and dissolution. When conjugated with D-Ala1-peptide T-amide (DAPTA), the core-shell tripods showed great enhancement in targeting the C-C chemokine receptor 5 (CCR5), a newly identified theranostic target up-regulated in triple negative breast cancer (TNBC). Specifically, the CCR5-targeted tripods with an arm length of about 45 nm showed 2-and 6-fold increase in tumor-to-blood and tumor-to-muscle uptake ratios, respectively, relative to their nontargeted counterpart in an orthotopic mouse 4T1 TNBC model at 24 h postinjection. The targeting specificity was further validated via a competitive receptor blocking study. We also demonstrated the use of these targeted, radioactive tripods for effective photothermal treatment in the 4T1 tumor model as guided by PET imaging. The efficacy of treatment was confirmed by the significant reduction in tumor metabolic activity revealed through the use of (18)F-fluorodeoxyglucose PET/CT imaging."

According to the news editors, the research concluded: "Taken together, we believe
that the (64)Cu-doped PdCu@Au tripods could serve as a multifunctional platform for both PET imaging and image-guided photothermal cancer therapy."

For more information on this research see: &amp;#8310;&amp;#8308;Cu-Doped PdCu@Au Tripods: A Multifunctional Nanomaterial for Positron Emission Tomography and Image-Guided Photothermal Cancer Treatment. Researchers from German Cancer Consortium Report Recent Findings in Starvation (FOXO3a orchestrates glioma cell responses to starvation conditions and promotes hypoxia-induced cell death)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Nutritional and Metabolic Diseases and Conditions - Starvation have been published. According to news originating from Frankfurt, Germany, by NewsRx correspondents, research stated, "Forkhead box O (FOXO) transcription factors are homeostatic regulators adjusting diverse cellular processes crucial for metabolism and survival. In gliomas, FOXOs have been shown to modulate cell death, proliferation and differentiation."

Our news journalists obtained a quote from the research from German Cancer Consortium, "Here, we investigated the role of FOXO3a in human malignant gliomas with special regard to starvation conditions. Expression of FOXO3a increased with WHO grade and was accentuated in the perinecrotic niche, colocalizing with hypoxia-inducible factor I alpha (HIF1 alpha) expression. FOXO3a was upregulated in hypoxia and translocation of FOXO3a from the cytoplasm to the nucleus was induced by serum starvation, pharmacological inhibition of protein kinase B (PKB) and hypoxia. Overexpression of FOXO3a induced tumor necrosis factor -related apoptosis-inducing ligand (TRAIL) expression and resulted in spontaneous cell death. Knockdown of FOXO3a (shFOXO3a), on the one hand, enhanced the sensitivity of glioma cells towards H2O2 under normoxia. On the other hand, it decreased consumption of glucose and oxygen, resulting in improved survival during glucose and oxygen deprivation. Mechanistically, in shFOXO3a cells, hypoxia-response element reporter activity, as well as the expression of common HIF1 alpha target genes, was increased, suggesting disinhibited HIF1 alpha signaling. However, glucose transporter 1 (GLUT1) expression was inversely regulated, and this may have been caused by an upregulation of TP53 in shFOXO3a cells. These data
reveal a novel role of FOXO3a-dependent gene regulation in the complex adaptive responses of gliomas towards starvation signals."

According to the news editors, the research concluded: "Strategies that target FOXO3a function may directly or indirectly alter glioma cell behavior and viability in the hypoxic niche."

For more information on this research see: FOXO3a orchestrates glioma cell responses to starvation conditions and promotes hypoxia-induced cell death. *International Journal of Oncology*, 2016;49(6):2399-2410. *International Journal of Oncology* can be contacted at: Spandidos Publ Ltd, Pob 18179, Athens, 116 10, Greece.

**Heart Disorders and Diseases - Left Ventricular**

**Researchers from German Center Lung Research Report Findings in Left Ventricular Hypertrophy (Cardiomyocyte loss is not required for the progression of left ventricular hypertrophy induced by pressure overload in female mice)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Heart Disorders and Diseases - Left Ventricular Hypertrophy. According to news originating from Hannover, Germany, by NewsRx correspondents, research stated, "Left ventricular (LV) hypertrophy in response to hypertension and increased afterload frequently progresses to heart failure. It is under debate whether the loss of cardiomyocytes contributes to this transition."

Financial support for this research came from Medical University of Graz.

Our news journalists obtained a quote from the research from German Center Lung Research, "To address this question, female C57BL/6 wild-type mice were subjected to transverse aortic constriction (TAC) and developed compensated LV hypertrophy after 1 week, which progressed to heart failure characterized by reduced ejection fraction and pulmonary congestion 4 weeks post-TAC. Quantitative, design-based stereology methods were used to estimate number and mean volume of LV cardiomyocytes. DNA strand breaks were visualized using the TUNEL method 6 weeks post-TAC to quantify the number of apoptotic cell nuclei. The volume of the LV myocardium as well as the cardiomyocyte mean volume increased progressively after TAC. In contrast, the number of LV cardiomyocytes remained constant 1 and 4 weeks post-TAC in comparison to sham-operated mice. Moreover, there was no significant difference in the number of cardiomyocyte nuclei stained for DNA strand breaks at 6 weeks post-TAC."

According to the news editors, the research concluded: "It was concluded that the loss of cardiomyocytes is not required for the transition from compensated hypertrophy to heart
failure induced by TAC in the female murine heart."

The news correspondents report that additional information may be obtained from C. Muhlfeld, German Center Lung Res DZL, Biomed Res Endstage & Obstruct Lung Dis Hannover, Hannover, Germany. Additional authors for this research include C. Grimm, G. Arnstein, J. Kockskamper, S. Sedej and C. Muhlfeld.

**Oncology - Gliomas**

**Researchers from Gifu Pharmaceutical University Report Findings in Gliomas [Glycoprotein nonmetastatic melanoma protein B (GPNMB) promotes the progression of brain glioblastoma via Na+/K+-ATPase]**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Oncology - Gliomas. According to news reporting from Gifu, Japan, by NewsRx journalists, research stated, "Glycoprotein nonmetastatic melanoma protein B (GPNMB), which is involved in invasion and metastasis, was found to be overexpressed in various cancers. High levels of GPNMB and Na+/K+-ATPase alpha subunits are associated with a poor prognosis in glioblastoma patients."

The news correspondents obtained a quote from the research from Gifu Pharmaceutical University, "We showed that GPNMB interacts with Na+/K+-ATPase alpha subunits to activate PI3K/Akt and MEK/ERK pathways. However, it remains unclear whether the interaction of GPNMB and Na+/K+-ATPase alpha subunits is involves in progression of glioma. The tumor size induced by the injection of glioma GL261 cells was larger in transgenic mice over expressing GPNMB when compared with wild-type mice. Additionally, the interaction of GPNMB and Na+/K+-ATPase alpha subunits was identified in the murine glioma model and in the tumors of glioblastoma patients. Ouabain, a Na+/K+-ATPase inhibitor, suppressed the glioma growth induced by the injection of glioma cells in the transgenic mice overexpressing GPNMB and blocked the GPNMB-induced migration of glioma cells. These findings indicate that GPNMB promotes glioma growth via Na+/K+-ATPase alpha subunits."

According to the news reporters, the research concluded: "Thus, the interaction between GPNMB and Na+/K+-ATPase alpha subunits represents a novel therapeutic target for the treatment of brain glioblastomas."

**Oncology**

**Researchers from H. Lee Moffitt Cancer Center and Research Institute Report on Findings in Oncology (A phase I study of indoximod in patients with advanced malignancies)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Oncology. According to news reporting out of Tampa, Florida, by NewsRx editors, research stated, "Indoximod is an oral inhibitor of the indoleamine 2,3-dioxygenase pathway, which causes tumor-mediated immunosuppression. Primary endpoints were maximum tolerated dose (MTD) and toxicity for indoximod in patients with advanced solid tumors."

Our news journalists obtained a quote from the research from H. Lee Moffitt Cancer Center and Research Institute, "Secondary endpoints included response rates, pharmacokinetics, and immune correlates. Our 3+3 phase I trial comprised 10 dose levels (200, 300, 400, 600, and 800 mg once/day; 600, 800, 1200, 1600, and 2000 mg twice/day). Inclusion criteria were measurable metastatic solid malignancy, age (>=)18 years, and adequate organ/marrow function. Exclusion criteria were chemotherapy (<=) 3 weeks prior, untreated brain metastases, autoimmune disease, or malabsorption. In 48 patients, MTD was not reached at 2000 mg twice/day. At 200 mg once/day, 3 patients previously treated with checkpoint inhibitors developed hypophysitis. Five patients showed stable disease >6 months. Indoximod plasma AUC and Cmax plateaued above 1200mg. Cmax (~12 mM at 2000 mg twice/day) occurred at 2.9 hours, and half-life was 10.5 hours. C reactive protein (CRP) levels increased across multiple dose levels. Indoximod was safe at doses up to 2000 mg orally twice/day. Best response was stable disease >6 months in 5 patients."

According to the news editors, the research concluded: "Induction of hypophysitis, increased tumor antigen autoantibodies and CRP levels were observed."
Researchers from Hacettepe University School of Medicine Detail Findings in Thyroid Cancer (Genetic Alterations in Differentiated Thyroid Cancer Patients with Acromegaly)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Oncology - Thyroid Cancer. According to news reporting originating from Ankara, Turkey, by NewsRx correspondents, research stated, "Acromegaly is associated with increased thyroid cancer risk. We aimed to analyze the frequency of point mutations of BRAF and RAS genes, and RET/PTC, PAX8/PPARg gene rearrangements in patients with acromegaly having differentiated thyroid cancers (DTC) and their relation with clinical and histological features. 14 acromegalic patients (8 male, 6 female) with DTC were included."

Our news editors obtained a quote from the research from the Hacettepe University School of Medicine, "BRAF V600E and NRAS codon 61 point mutations, RET/PTC1, RET/PTC3, and PAX8/PPARg gene rearrangements were analyzed in thyroidectomy specimens. We selected 14 non-acromegalic patients with DTC as a control group. 2 patients (14.3%) were detected to have positive BRAF V600E and 3 patients (21.4%) were detected to have NRAS codon 61 mutation. NRAS codon 61 was the most frequent genetic alteration. Patients with positive mutation had aggressive histologic features more frequently than patients without mutations. Comparison of the acromegalic and non-acromegalic patients with DTC revealed that BRAF V600E mutation was more frequent in non-acromegalic patients with DTC (14.2% vs. 64.3%, p=0.02). RET/PTC 1/ 3, PAX8/PPARg gene rearrangements were not detected in any patient. None of the patients including the patients with positive point mutations had recurrence, and local and/or distant metastasis. NRAS codon 61 is the most frequent genetic alteration in this acromegaly series with DTC. Since acromegalic patients have lower prevalence of BRAF V600E mutation, BRAF V600E mutation may not be a causative factor in development of DTC in acromegaly."

According to the news editors, the research concluded: "Despite the relation of BRAF V600E and NRAS codon 61 mutations with aggressive histopathologic features, their impact on tumor prognosis remains to be defined in acromegaly in further studies."
For more information on this research see: Genetic Alterations in Differentiated Thyroid Cancer Patients with Acromegaly. *Experimental and Clinical Endocrinology & Diabetes*, 2015;124(3):198-202. (Thieme - www.thieme.com)

The news editors report that additional information may be obtained by contacting K. Aydin, Dept. of Endocrinology and Metabolism, Hacettepe University School of Medicine, Ankara, Turkey. Additional authors for this research include C. Aydin, S. Dagdelen, G.G. Tezel and T. Erbas.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1055/s-0035-1565061. This DOI is a link to an online electronic document that is either free or for purchase.

**Digestive System Diseases and Conditions - Acid...**

**Researchers from Hamamatsu University School of Medicine Detail New Studies and Findings in the Area of Acid Reflux Disease (Rapid metabolizer genotype of CYP2C19 is a risk factor of being refractory to proton pump inhibitor therapy for reflux ...)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Digestive System Diseases and Conditions - Acid Reflux Disease. According to news reporting originating in Hamamatsu, Japan, by NewsRx journalists, research stated, "Proton pump inhibitors (PPIs) are mainly metabolized by cytochrome P450 2C19 (CYP2C19) and used as the first-line therapy for gastroesophageal reflux disease (GERD). However, while several studies have examined the influence of CYP2C19 polymorphism on GERD treatment with PPIs, most have had small sample sizes and were conducted in a single center."

The news reporters obtained a quote from the research from the Hamamatsu University School of Medicine, "Here, we used meta-analysis to investigate whether or not the CYP2C19 rapid metabolizer (RM) genotype is a risk factor for GERD patients being refractory to PPI therapy. PubMed and other electronic databases were systematically searched up to August 2014 using the following terms: 'GERD and CYP2C19', 'esophagitis and CYP2C19', and 'non-erosive reflux disease and CYP2C19.' Searches were limited to publications in English, and two investigators evaluated eligible studies and extracted data. The total efficacy rate of PPIs for GERD, including reflux esophagitis (RE) and non-erosive reflux disease, was 56.4% (95% confidence interval [CI]; 53.9-58.9%, 870/1543) in intention-to-treat analysis and 63.8% (95% CI; 61.3-66.2%, 950/1489) in per-protocol analysis. Efficacy rates varied significantly between CYP2C19 genotypes (intention-to-treat analysis: RMs, 52.2% [315/604]; intermediate metabolizers, 56.7% [298/526]; poor metabolizers [PMs], 61.3% [138/225]; p=0.047). Among RE patients, CYP2C19 RMs had an increased risk of being refractory to PPI therapy compared with PMs (odds ratio: 1.661, 95% CI: 1.023-2.659, p=0.040). The present meta-analysis
demonstrates that CYP2C19 RMs with RE have an increased risk of being refractory to PPI therapy compared with PMs.

According to the news reporters, the research concluded: "Individualized dosing regimen with PPIs based on CYP2C19 genotype might be a valid therapeutic strategy for overcoming insufficient gastric acid inhibition."

Our news correspondents report that additional information may be obtained by contacting H. Ichikawa, First Dept. of Medicine, Hamamatsu University School of Medicine, Hamamatsu, Shizuoka, Japan. Additional authors for this research include M. Sugimoto, K. Sugimoto, A. Andoh and T. Furuta.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1111/jgh.13233. This DOI is a link to an online electronic document that is either free or for purchase.

### Apoptosis

**Researchers from Harbin Medical University Describe Findings in Apoptosis [Lysine-Specific Demethylase 1 (LSD1) Inhibitor S2101 Induces Autophagy via the AKT/mTOR Pathway in SKOV3 Ovarian Cancer Cells]**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Apoptosis have been published. According to news reporting originating in Heilongjiang, People's Republic of China, by NewsRx journalists, research stated, "S2101 is one of the most potent LSD1 inhibitors, which can inhibit ovarian cancer cells viability. This study aimed to detect the mechanism behind the anticancer properties of S2101 in SKOV3 ovarian cells."

The news reporters obtained a quote from the research from Harbin Medical University, "Cell viability was tested by Cell Counting Kit-8 (CCK-8) assay. Cellular apoptosis and autophagy were evaluated by flow cytometric analysis using Annexin-V/PI staining methods and Green fluorescent protein (GFP)-fused-LC3 (GFP-LC3), respectively. Western blotting was performed for analyzing the Bax, Bcl-2, mTOR, p-mTOR, p62, LC3-I, LC3-II, AKT, and p-AKT protein expression. Our results show that the proportion of early apoptotic and late apoptotic cells increased significantly for cells treated with S2101 at a concentration of 100 mu M for 48 h. Treatment of S2101 in SKOV3 cells resulted in upregulation of Bax and downregulation of Bcl-2 in a time-dependent manner, indicating that S2101 can induce...
apoptosis in SKOV3. There was a downward trend in the expression of p62 when the SKOV3 cells were treated with 100 μm S2101 for 12 h, 24 h and 48 h. The conversion of LC3-I to LC3-II was increased significantly at 24 h and 48 h. Autophagy was induced by S2101 in SKOV3 cells, evidenced by an increase in punctuate localization of GFP-LC3 and a change in expression of autophagy-related proteins. S2101 treatment decreased the levels of phosphorylated AKT and mTOR. S2101 inhibits SKOV3 cells viability and induces apoptosis and autophagy.*

According to the news reporters, the research concluded: "The AKT/mTOR signaling pathway was found to be affected by S2101."

For more information on this research see: Lysine-Specific Demethylase 1 (LSD1) Inhibitor S2101 Induces Autophagy via the AKT/mTOR Pathway in SKOV3 Ovarian Cancer Cells. *Medical Science Monitor*, 2016;22():4742-4748. *Medical Science Monitor* can be contacted at: Int Scientific Literature, Inc, 361 Forest Lane, Smithtown, NY 11787, USA.

Our news correspondents report that additional information may be obtained by contacting J.H. Zheng, Harbin Med Univ, Dept. of Obstet & Gynecol, Affiliated Hosp 1, Harbin, Heilongjiang, People's Republic of China. Additional authors for this research include Y. Jin, M.J. Cui and J.H. Zheng.

**Cardiology**

**Researchers from Harvard School of Medicine Describe Findings in Cardiology (A Systematic Review of Mitral Valve Repair With Autologous Pericardial Leaflet Augmentation for Rheumatic Mitral Regurgitation)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Cardiology are discussed in a new report. According to news originating from Boston, Massachusetts, by NewsRx correspondents, research stated, "A systematic review was conducted to assess the efficacy of mitral valve repair using glutaraldehyde-treated autologous pericardial leaflet augmentation for rheumatic mitral regurgitation (MR). Five retrospective studies were identified, which included 196 patients with moderate or greater MR."

Our news journalists obtained a quote from the research from the Harvard School of Medicine, "There was 1 operative death (0.5%). At a mean follow-up of 3.2 +/- 2.2 years, moderate or greater MR reoccurred in 22 patients (11.2%), reoperation was required in 9 (4.6%), and the cumulative survival was 98.9%. Finally, outcomes were similar between the patients who underwent augmentation of the anterior vs the posterior mitral leaflet."

According to the news editors, the research concluded: "Pericardial leaflet
augmentation is a viable technique for the treatment of rheumatic MR."

The news correspondents report that additional information may be obtained from C.G. Mihos, Harvard Med Sch, Massachusetts General Hospital, Cardiac Ultrasound Lab, Boston, MA 02114, United States. Additional authors for this research include A.M. Pineda, R. Capoulade and O. Santana.

Heart Disorders and Diseases - Atrial Fibrillation

Researchers from Harvard School of Medicine Detail New Studies and Findings in the Area of Atrial Fibrillation (Atrial fibrillation associated hospitalizations in patients with end-stage renal disease in the United States, 2003-2012)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Heart Disorders and Diseases - Atrial Fibrillation is the subject of a report. According to news reporting out of Cambridge, Massachusetts, by NewsRx editors, research stated, "Atrial fibrillation (AF) is highly prevalent in patients with end-stage renal disease (ESRD). The clinical and economic burden of AF-associated hospitalizations has not been previously quantified in the ESRD population in the United States."

Our news journalists obtained a quote from the research from the Harvard School of Medicine, "The aim of this study was to assess the incidence and outcomes of AF hospitalizations in the US ESRD population. We used the 2003-2012 National Inpatient Sample database to study trends in the incidence and outcomes of AF hospitalizations in ESRD patients. Primary outcomes included hospitalization rate, in-hospital case fatality ratio (CFR), length of stay (LOS), and cost. There were 66,811 primary and 986,742 secondary AF hospitalizations associated with ESRD. The mean age of the patients was 70.9 years, and 45.2% were women. The age-adjusted primary AF hospitalization rate increased from 10.1 to 14.0 per 1000 ESRD patients, while the secondary AF hospitalization rate increased from 164.0 to 212.8 per 1000 ESRD patients (P-trend < 0.05 for both). There was a significant decrease in CFR (2.9%-2.7% for primary AF and 11.3%-7.7% for secondary AF; P-trend <.001 for both), mean LOS (6.0-4.8 days for primary AF and 9.8-7.1 days for secondary AF; P-trend <.001 for both), and mean cost ($14,395-$11,184 for primary AF and $25,545-$17,879 for secondary AF; P-trend <.001 for both). There was a greater than 2-fold increase in the annual number of AF hospitalizations along with a significant increase in AF hospitalization rate in the US ESRD population."
According to the news editors, the research concluded: "There were significant improvements in markers of quality of care, including inhospital CFR, LOS, and cost."

Our news journalists report that additional information may be obtained by contacting N. Kumar, Harvard Med Sch, Cambridge Hlth Alliance, Dept. of Med, Cambridge, MA 02139, United States. Additional authors for this research include R. Khera and N. Garg.

Keywords for this news article include: Cambridge, Massachusetts, United States, North and Central America, Heart Disorders and Diseases, End Stage Renal Disease, Atrial Fibrillation, Cardiac Arrhythmias, Heart Disease, Nephrology, Kidney, Harvard School of Medicine.

**Cardiovascular Diseases**

**Researchers from Harvard School of Medicine Report Details of New Studies and Findings in the Area of Cardiovascular Diseases (Thyroid function and cardiovascular disease risk factors in euthyroid adults: a cross-sectional and longitudinal study)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Cardiovascular Diseases. According to news reporting originating from Boston, Massachusetts, by NewsRx correspondents, research stated, "Objective and designWe explored the cross-sectional and longitudinal associations of thyroid function within the normal range with cardiovascular disease (CVD) risk factors and adiposity measures. Patients and measurementsA total of 3483 (504% women) participants for the cross-sectional CVD study and 1630 (412% women) participants for the cross-sectional body composition substudy were drawn from the Framingham Third Generation Exam 1; 2912 participants (501% women) for the longitudinal CVD study and 713 participants (359% women) for the longitudinal body composition substudy were drawn from the Framingham Third Generation Exams 1-2."

Financial support for this research came from National Heart, Lung, and Blood Institute.

Our news editors obtained a quote from the research from the Harvard School of Medicine, "Thyroid function was assessed by thyrotropin [thyroid-stimulating hormone (TSH)] and free thyroxine (fT4) concentrations within the reference range at Exam 1. The associations between thyroid function and CVD risk factors were modelled via multivariable-adjusted regression models. Multivariable adjustment included age, sex, current smoking, postmenopausal status and BMI. ResultsCross-sectionally, higher TSH concentration was associated with increased odds of hypertriglyceridaemia [odds ratio (OR)=110], and higher BMI ( = 019 kg/m(2)), total cholesterol ( = 005 mmol/l), triglycerides ( = 0006 mmol/l) and subcutaneous adipose tissue (SAT) volume ( = 388 cm(3)) (all P< 005). Cross-sectionally, fT4 was inversely associated with metabolic and adiposity-related CVD risk factors, including
obesity (OR = 117), hypertriglyceridaemia (OR = 109), BMI ( = 042 kg/m(2)), total cholesterol ( = 005 mmol/l), triglycerides ( = 0002 mmol/l), visceral adipose tissue (VAT) volume ( = -207 cm(3)) and attenuation (017 HU) and VAT/SAT ratio ( = -001) (all P< 005). However, during 61 years of follow-up, baseline TSH and fT4 levels were not longitudinally associated with CVD risk factors and adiposity measures.

According to the news editors, the research concluded: "Conclusions Thyroid function within the normal range is cross-sectionally, but not longitudinally, associated with CVD risk factors and adiposity measures."

The news editors report that additional information may be obtained by contacting C.S. Fox, Harvard Med Sch, Boston, MA, United States. Additional authors for this research include A. Pedley, E. Marqusee, P. Sutherland, U. Hoffmann, J.M. Massaro and C.S. Fox.

Eye Diseases

Researchers from Harvard School of Medicine Report Findings in Eye Diseases (Orbital Angiogenesis and Lymphangiogenesis in Thyroid Eye Disease An Analysis of Vascular Growth Factors with Clinical Correlation)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Eye Diseases have been published. According to news reporting from Boston, Massachusetts, by NewsRx journalists, research stated, "The human orbit is an environment that is vulnerable to inflammation and edema in the setting of autoimmune thyroid disease. Our study investigated the tenet that orbital adipose tissue lacks lymphatic vessels and analyzed the clinicopathologic differences between patients with acute and chronic thyroid eye disease (TED)."

The news correspondents obtained a quote from the research from the Harvard School of Medicine, "The underlying molecular mediators of blood and lymphatic vessel formation within the orbital fat also were evaluated. Retrospective cohort study. The study included fat specimens from 26 orbits of 15 patients with TED undergoing orbital decompression. Orbital fat specimens from patients without TED as well as cadaveric orbital fat served as controls. Tissue specimens were processed as formalin-fixed, paraffin-embedded sections or frozen cryosections for immunohistochemistry. Total RNA was extracted and
analyzed via quantitative (real-time) reverse-transcription polymerase chain reaction. Clinicopathologic correlation was made by determining the clinical activity score (CAS) of each patient with TED. Samples were examined for vascular and lymphatic markers including podoplanin, lymphatic vessel endothelial hyaluronan receptor 1 (LYVE-1), and cluster of differentiation 31 (CD31) by immunohistochemistry, as well as for mRNA levels of vascular endothelial growth factor (VEGF), VEGF receptors, semaphorin 3F, neuropilin 1, neuropilin 2, podoplanin, and LYVE-1 by quantitative (real-time) reverse-transcription polymerase chain reaction. Clinicopathologic correlation revealed increased staining of CD31-positive blood vessels in patients with acute TED with a CAS more than 4, as well as rare staining of podoplanin-positive lymphatic vessels within acutely inflamed orbital fat tissue. Additionally, quantitative (real-time) reverse-transcription polymerase chain reaction analysis demonstrated increased expression of VEGF receptor (VEGFR) 2 as well as VEGF signaling molecules VEGF-A, VEGF-C, and VEGF-D. In acute TED, compared with chronic TED and control orbital fat, there is increased blood vessel density, suggesting neovascularization and rare lymphatic vessels suggestive of limited lymphangiogenesis. This proangiogenic and prolymphangiogenic microenvironment is likely the result of the increased expression of VEGFR-2, VEGF-A, VEGF-C, and VEGF-D."

According to the news reporters, the research concluded: "These findings imply that orbital edema in acute TED may be mediated, in part, by both the formation of new, immature blood vessels and the formation of lymphatic capillaries that are functionally incapable of draining interstitial fluid."

**Hematopoiesis**

**Researchers from Harvard Stem Cell Institute Detail New Studies and Findings in the Area of Hematopoiesis (Understanding the regulation of vertebrate hematopoiesis and blood disorders - big lessons from a small fish)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness
& Wellness Week -- New research on Hematopoiesis is the subject of a report. According to news reporting originating from Boston, Massachusetts, by NewsRx correspondents, research stated, "Hematopoietic stem cells (HSCs) give rise to all differentiated blood cells. Understanding the mechanisms that regulate self-renewal and lineage specification of HSCs is key for developing treatments for many human diseases."

Our news editors obtained a quote from the research from Harvard Stem Cell Institute, "Zebrafish have emerged as an excellent model for studying vertebrate hematopoiesis. This review will highlight the unique strengths of zebrafish and important findings that have emerged from studies of blood development and disorders using this system. We discuss recent advances in our understanding of hematopoiesis, including the origin of HSCs, molecular control of their development, and key signaling pathways involved in their regulation."

According to the news editors, the research concluded: "We highlight significant findings from zebrafish models of blood disorders and discuss their application for investigating stem cell dysfunction in disease and for the development of new therapeutics."

The news editors report that additional information may be obtained by contacting L.I. Zon, Boston Childrens Hosp, Harvard Stem Cell Inst, Howard Hughes Med Inst, Boston, MA, United States. Additional authors for this research include S. Avagyan, J.M. Gansner and L.I. Zon.

**Oncology - Lung Cancer**

Researchers from Hasselt University Report Recent Findings in Lung Cancer (Postoperative radiotherapy for lung cancer: Is it worth the controversy?)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Oncology - Lung Cancer have been published. According to news reporting from Hasselt, Belgium, by NewsRx journalists, research stated, "The role of postoperative radiation therapy (PORT) in patients with completely resected non-small cell lung cancer (NSCLC) with pathologically involved mediastinal lymph nodes (N2) remains unclear. Despite a reduction of local recurrence (LR), its effect on overall survival (OS) remains unproven."

Financial supporters for this research include LCRP, Limburg Sterk Merk, Hasselt University, ziekenhuis Oost-Limburg, Jessa Hospital, Limburg Cancer Foundation, Kom op
The news correspondents obtained a quote from the research from Hasselt University, "Therefore we conducted a review of the current literature. To investigate the benefit and safety of modern PORT, we identified published phase III trials for PORT. We investigated modern PORT in low-risk (ypN0/1 and RO) and high-risk (ypN2 and/or R1/2) patients with stage III-N2 NSCLC treated with induction chemotherapy and resection. Seventeen phase III trials using PORT were selected. Of all PORT N2 studies, 4 were eligible for evaluation of LR, all in high-risk patients only. In these high-risk patients receiving PORT, the mean LR rate at 5 years was 20.9% (95% CI 16-24). Two trials were suitable to assess LR rates after chemotherapy and surgery without PORT. In these low-risk patients, the mean 5-year LR was 33.1% (95% CI 27-39). No significant difference in non-cancer deaths between PORT vs. non-PORT patients was observed in N2 NSCLC. PORT is worth the controversy because data illustrate that PORT may increase the OS."

According to the news reporters, the research concluded: "However, prospective randomized trials are needed to verify this."

Our news journalists report that additional information may be obtained by contacting C. Billiet, Hasselt Univ, Fac Med & Life Sci, B-3500 Hasselt, Belgium. Additional authors for this research include S. Peeters, H. Decaluwe, J. Vansteenkiste, J. Mebis and D. De Ruyscher.

Researchers from Health Institute Detail Findings in Cholestasis [Liver Transplantation in Polish Children With alpha(1)-Antitrypsin Deficiency: A Single-Center Experience]

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Digestive System Diseases and Conditions - Cholestasis are presented in a new report. According to news reporting from Warsaw, Poland, by NewsRx journalists, research stated, "Alpha(1)-Antitrypsin deficiency (ATD) is the most common genetic cause of liver injury in young children. Asymptomatic hepatitis is observed in most patients."

The news correspondents obtained a quote from the research from Health Institute, "However, the course of liver disease due to ATD is unpredictable, and some children develop..."
liver cirrhosis. Liver transplantation (Ltx) dramatically improves their outcome and in some cases is required in the first years of life. The aim of the study was to evaluate the course of the disease in children with ATD treated with Ltx in a single center. We retrospectively reviewed the clinical features (ascites, esophageal varices, esophageal bleeding) and laboratory parameters of liver function in children with ATD who were treated with Ltx. Twenty-two Ltxs were performed in 20 children (13 boys, 7 girls). Median age at transplantation was 12 years (range 0.5 to 17.1). Four children were transplanted in the first 2 years of life and 16 patients were over 7 years old. The indications for Ltx in younger children were progressive cholestasis with coagulopathy and ascites. In older patients, the indications were as follows: liver failure presenting with variceal bleeding in 7 patients, ascites in 5 patients, hypersplenism in all but 1 patient. In the group of children transplanted over 7 years old, the frequency of cholestasis decreased intermittently in the second year of life: 4 patients (25%) compared to 15 patients (94%) and 10 patients (63%) in the neonatal and pre-transplant period, respectively. In the group of children transplanted earlier, cholestasis and hepatitis were maintained until Ltx. Of transplanted patients, 50% were malnourished at the transplantation, and 50% were followed for more than 10 years. Five-year post-transplant survival was 100% (n = 14), and 10-year survival was 90%. Two patients died as adults with biliary post-transplant complications and problems with compliance. Our experience suggests that transient normalization of liver parameters in some patients with ATD do not exclude the liver disease progression to cirrhosis and unfavorable outcome of liver disease in childhood. In our group of patients, median age at transplantation was high compared to other centers.

According to the news reporters, the research concluded: "The long-term prognosis in children after transplantation is very good, but early post-transplant complications and probable problems with compliance in young adults may lead to graft failure."

Our news journalists report that additional information may be obtained by contacting A. Bakula, Childrens Mem Hlth Inst, Gastroenterol Hepatol Nutr Disorders & Paediat, Warsaw, Poland. Researchers from Health Research Institute Detail Findings in Antiarrhythmic Agents (Short-term esmolol attenuates remodeling of the thoracic aorta in hypertensive rats by decreasing concentrations of ADMA down-regulated by oxidative stress)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Drugs and Therapies - Antiarrhythmic Agents is now available. According to news originating from Madrid, Spain, by NewsRx correspondents, research stated, "Esmolol produces early regression of left ventricular hypertrophy and improves coronary artery remodeling, although the impact of short-term treatment with this beta-blocker on remodeling in large arteries has not yet been studied. We hypothesized that even a short (48 h) course of esmolol might alter remodeling of the aorta in the spontaneously hypertensive rat (SHR)."

Financial support for this research came from Spanish Health Ministry (Fondo de Investigaciones Sanitarias).

Our news journalists obtained a quote from the research from Health Research Institute, "Fourteen-month-old male SHRs were treated intravenously with vehicle (SHR, n=8) or esmolol (SHR-E, n=8) (300 μg/kg/min). Age matched, vehicle-treated male Wistar-Kyoto rats (WKY, n=8) served as controls. After 48 h, we studied the structure, volume density of elastic fibers, and passive mechanical properties of the aorta. Determination of asymmetrical dimethylarginine concentrations and total protein carbonyls in the aorta were analyzed. Esmolol significantly attenuated abnormal aortic wall thickness, cross-sectional area, wall-to-lumen ratio, volume density of elastic fibers, and wall stiffness. The protective effect of esmolol could be related to a decrease in asymmetrical dimethylarginine levels after down-regulation by oxidative stress."

According to the news editors, the research concluded: "These findings could play a key role in the selection of antihypertensive therapy in patients with hypertension and aortic remodeling."

For more information on this research see: Short-term esmolol attenuates remodeling of the thoracic aorta in hypertensive rats by decreasing concentrations of ADMA down-regulated by oxidative stress. Researchers from Health Science Center Report Recent Findings in Antiretrovirals (Population Pharmacokinetics of Tenofovir in HIV-1-Uninfected Members of Serodiscordant Couples and Effect of Dose Reporting Methods)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Drugs and Therapies - Antiretrovirals. According to news reporting out of Fort Worth, Texas, by NewsRx editors, research stated, "Antiretroviral preexposure prophylaxis (PrEP) with once-daily dosing of tenofovir and tenofovir-emtricitabine was shown to be effective for preventing HIV-1 infection in individuals who had HIV-1-seropositive partners (the Partners PrEP Study). We developed a population pharmacokinetic model for tenofovir and investigated the impacts of different dose reporting methods."

Our news journalists obtained a quote from the research from Health Science Center, "Dosing information was collected as patient-reported dosing information (PRDI) from 404 subjects (corresponding to 1,280 drug concentration records) from the main trial and electronic monitoring-based adherence data collected from 211 subjects (corresponding to 327 drug concentration records) in an ancillary adherence study. Model development was conducted with NONMEM (7.2), using PRDI with a steady-state assumption or using PRDI replaced with electronic monitoring records where available. A two-compartment model with first-order absorption was the best model in both modeling approaches, with the need for an absorption lag time when electronic monitoring-based dosing records were included in the analysis. Age, body weight, and creatinine clearance were significant covariates on clearance, but only creatinine clearance was retained in the final models per stepwise selection. Sex was not a significant covariate on clearance. Tenofovir population pharmacokinetic parameter estimates and the precisions of the parameters from the two final models were comparable with the point estimates of the parameters, differing from 0% to 35%, and bootstrap confidence intervals widely overlapped."

According to the news editors, the research concluded: "These findings indicate that PRDI was sufficient for population pharmacokinetic model development in this study, with a high level of adherence per multiple measures."

For more information on this research see: Population Pharmacokinetics of Tenofovir in HIV-1-Uninfected Members of Serodiscordant Couples and Effect of Dose Reporting Methods. Antimicrobial Agents and Chemotherapy, 2016;60(9):5379-5386. Antimicrobial Agents and Chemotherapy can be contacted at: Amer Soc Microbiology, 1752 N St NW, Washington, DC 20036-2904, USA. (American Society for Microbiology - www.asm.org; Antimicrobial Agents and Chemotherapy - aac.asm.org)

Our news journalists report that additional information may be obtained by contacting A. Chaturvedula, Univ North Texas, Hlth Sci Center, Pharmacotherapy, Fort Worth, TX 76107, United States. Researchers from Heart Center Report New Studies and Findings in the Area of Heart Bypass Surgery (Long-Term Follow-Up of Patients With Previous Coronary Artery Bypass Grafting Undergoing Percutaneous Coronary Intervention for Chronic Total ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Surgery - Heart Bypass Surgery have been published. According to news reporting out of Bad Krozingen, Germany, by NewsRx editors, research stated, "Successful revascularization of chronic total occlusions (CTOs) has been associated with clinical benefit. Data on outcomes in patients with previous coronary artery bypass grafting (CABG) undergoing percutaneous coronary intervention (PCI) for CTO, however, are scarce."

Our news journalists obtained a quote from the research from Heart Center, "A total of 2,002 consecutive patients undergoing PCI for CTO from January 2005 to December 2013 were divided into patients with and without previous CABG, and outcomes were retrospectively assessed. The primary outcome measure was all-cause mortality. Median follow-up was 2.6 years (interquartile range 1.1 to 3.1). A total of 292 patients (15%) had previous CABG; they were older and had a greater prevalence of comorbidities. Procedural success was achieved in 75% and 84% Of patients in the previous CABG and the non-CABG groups (p <0.001), respectively. All-cause mortality was 16% and 11% in the previous CABG and the non-CABG groups (p = 0.002), and differences were mitigated after adjustment for baseline characteristics (adjusted hazard ratio [HR] 1.22, 95% confidence interval [CI] 0.86 to 1.74, p = 0.27). All-cause death was significantly reduced in patients with procedural success, both in the previous CABG (11% vs 32%, adjusted HR 0.43, 95% CI 0.24 to 0.77, p = 0.005) and the non-CABG groups (10% vs 20%, adjusted HR 0.63, 95% CI 0.45 to 0.86, p = 0.004), with similar mortality benefits associated with successful revascularization in both groups (interaction p = 0.24)."

According to the news editors, the research concluded: "The relative survival benefit of successful recanalization of CTO is independent of previous CABG. However, owing to a greater baseline risk, the absolute survival benefit of successful CTO procedures is more pronounced in patients with previous CABG than in non-CABG patients."

For more information on this research see: Long-Term Follow-Up of Patients With Previous Coronary Artery Bypass Grafting Undergoing Percutaneous Coronary Intervention for Chronic Total Occlusion. American Journal of Cardiology, 2016;118(11):1641-1646.
Researchers from Hebei Medical University Report New Studies and Findings in the Area of Thrombosis (Efficacy and safety of therapeutic anticoagulation for the treatment of isolated calf muscle vein thrombosis - a systematic review and ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Cardiovascular Diseases and Conditions - Thrombosis have been presented. According to news reporting out of Shijiazhuang, People's Republic of China, by NewsRx editors, research stated, "Diverse treatment suggestions range from monitoring with duplex examinations to therapeutic anticoagulation (TA) for managing isolated calf muscle vein thrombosis (ICMVT). However, the small sample sizes and low-level evidence provided by most studies in the literature mean that the benefits of promising new treatment protocols are unclear. Hence, this meta-analysis is intended to assess the efficacy and safety of TA for patients with ICMVT."

Our news journalists obtained a quote from the research from Hebei Medical University, "Articles comparing TA with no anticoagulation (NA) or no therapeutic anticoagulation (NTA) in patients with ICMVT were collected from PubMed, the Cochrane Library, EMBASE, and Web of Science. The risk ratio (RR) and 95% confidence interval (95% CI) were generated for each outcome of interest. The data were pooled using a random-effects or fixed effects model to evaluate differences in outcomes between the TA and control groups. Five of 377 initially identified papers were included. One randomized controlled trial, one non-randomized controlled trial and three retrospective cohort studies (a total of 744 patients, 390 in the TA group and the remaining 354 in the NA or NTA group) were included in this meta-analysis. The occurrence of thrombosis progression was significantly less frequent in those who received TA compared with those receiving NTA (RR = 0.33, 95% CI 0.20 to 0.54, p < 0.01). The rate of complete recanalization was higher, albeit not significantly, in the TA group than in the NTA group (RR = 1.96, 95% CI 1.01 to 3.80, p = 0.05). None of the pooled outcomes were significantly different when comparing the TA and NA groups. This study suggests that TA may result in a significant reduction in the rate of thrombosis progression and a marginally significant increase in the rate of complete recanalization for patients with ICMVT."
According to the news editors, the research concluded: "Further studies are needed to confirm these findings and clarify whether the benefits of TA outweigh the potential harm."

For more information on this research see: Efficacy and safety of therapeutic anticoagulation for the treatment of isolated calf muscle vein thrombosis - a systematic review and meta-analysis. Vasa-European Journal of Vascular Medicine, 2016;45(6):478-485. Oncology - Gliomas

Researchers from Henan University Provide Details of New Studies and Findings in the Area of Gliomas (Long non-coding RNA CCAT1 promotes glioma cell proliferation via inhibiting microRNA-410)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Oncology - Gliomas have been published. According to news originating from Kaifeng, People's Republic of China, by NewsRx correspondents, research stated, "Long non-coding RNAs have been confirmed to play a critical role in various cancers. In the present study, the effect of long non-coding RNA (IncRNA) CCAT1 on glioma cell proliferation and its potential mechanism were investigated."

Our news journalists obtained a quote from the research from Henan University, "Real-time PCR results showed that IncRNA-CCAT1 expression was significantly upregulated in glioma cancer tissues and cell lines compared with controls. After inhibiting CCAT1 expression in glioma cell line U251 with siRNA-CCAT1 (si-CCAT1), the cell viability and cell colony formation were decreased, the cell cycle was arrested in G1 phase, and the cell apoptosis was increased. As reported in bioinformatics software starbase2.0, a total of 22 microRNAs were potentially targeted by CCAT1. It was confirmed that miR-410 was altered most by si-CCAT1. After up-regulating CCAT1 expression in U251 cells, miR-410 level was decreased. Luciferase reporter assay confirmed that CCAT1 targeted miR-410. Correlation analysis showed that CCAT1 expression was negatively related to miR-410 expression in glioma cancer tissues. In addition, down-regulation of miR-410 reversed the inhibitory effect of si-CCAT1 on glioma proliferation."

According to the news editors, the research concluded: "These data demonstrated that IncRNA-CCAT1 promoted glioma cell proliferation via inhibiting miR-410, providing a

Tumor Markers - Carcinoembryonic Antigens

Researchers from Henan University of Technology Report Recent Findings in Carcinoembryonic Antigens (Differential pulse voltammetric assay for the carcinoembryonic antigen using a glassy carbon electrode modified with layered molybdenum ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Tumor Markers - Carcinoembryonic Antigens have been published. According to news reporting originating in Zhengzhou, People's Republic of China, by NewsRx editors, the research stated, "A highly sensitive electrochemical aptasensor is described for the determination of carcinoembryonic antigen (CEA). It is based on the use of a hybrid material composed of molybdenum selenide, graphene, and gold nanoparticles (AuNPs)."

Financial supporters for this research include National Natural Science Foundation of China, Youth Backbone Teacher Training Program of Henan University of Technology.

The news reporters obtained a quote from the research from the Henan University of Technology, "The MoSe2-graphene hybrid was prepared by a hydrothermal method and used as the supporting substrate. It was placed on the surface of a glassy carbon electrode onto which the AuNPs were electrochemically deposited. Thiol-labeled aptamer against CEA was immobilized on the electrode via gold-thiol binding. The use of AuNPs coupled to the MoSe2-graphene hybrid allows for a large loading with aptamers. Under optimum conditions and at a working potential of 0.21 V (vs."

According to the news reporters, the research concluded: "SCE), the assay has a linear calibration plot in the 0.1 pg mL(-1) to 100 ng mL(-1) CEA concentration range, with a detection limit of 0.03 pg mL(-1)."

For more information on this research see: Differential pulse voltammetric assay for
the carcinoembryonic antigen using a glassy carbon electrode modified with layered molybdenum selenide, graphene, and gold nanoparticles. *Microchimica Acta*, 2017;184(1):229-235. *Microchimica Acta* can be contacted at: Springer Wien, Sachsenplatz 4-6, PO Box 89, A-1201 Wien, Austria. Heart Disorders and Diseases - Endocarditis

Researchers from Henry Ford Hospital Discuss Findings in Endocarditis (False-positive cerebrospinal fluid cryptococcus antigen in Libman-Sacks endocarditis)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Heart Disorders and Diseases - Endocarditis. According to news reporting originating in Detroit, Michigan, by NewsRx journalists, research stated, "Cryptococcus meningoencephalitis is a serious opportunistic infection associated with high morbidity and mortality in immunocompromised hosts, particularly patients with advanced AIDS disease. The diagnosis is established through cerebrospinal fluid (CSF) cryptococcus antigen detection and cultures."

The news reporters obtained a quote from the research from Henry Ford Hospital, "Cryptococcus antigen testing is usually the initial test of choice due its high sensitivity and specificity along with the quick availability of the results. Case report We hereby report a case of a false-positive CSF cryptococcus antigen assay in a patient with systemic lupus erythematosus presenting with acute confusion. While initial CSF evaluation revealed a positive cryptococcus antigen assay, the patient's symptoms were inconsistent with cryptococcus meningoencephalitis. A repeat CSF evaluation, done 3 days later, revealed a negative CSF cryptococcus antigen assay."

According to the news reporters, the research concluded: "Given the patient's active lupus disease and the elevated antinuclear antibody titers, we believe that the initial positive result was a false positive caused by interference from autoantibodies."

For more information on this research see: False-positive cerebrospinal fluid cryptococcus antigen in Libman-Sacks endocarditis. *Infection*, 2016;44(6):803-805. *Infection* can be contacted at: Springer Heidelberg, Tiergartenstrasse 17, D-69121 Heidelberg, Germany. (Springer - www.springer.com; Infection - www.springerlink.com/content/0300-8126/)
Researchers from Hokkaido University School of Medicine Report New Studies and Findings in the Area of Gastric Cancer (Concomitant neoplasms in the skin and stomach unveil the role of type IV collagen and E-cadherin in mucin core protein 5AC ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Oncology - Gastric Cancer have been published. According to news reporting originating in Sapporo, Japan, by NewsRx journalists, research stated, "Mucin core protein (MUC) 5AC is a gel-forming glycoprotein that is expressed in different types of tumor cells. MUC5AC expression in cultured cells is regulated through the extracellular matrix and through remodelling by other membranous proteins such as type IV collagen (COL4) and E-cadherin."

The news reporters obtained a quote from the research from the Hokkaido University School of Medicine, "However, it has not been elucidated whether COL4 and E-cadherin affect MUC5AC expression in tumours in vivo. Here, by analysing a single individual with concomitant neoplasms in the skin [extramammary Paget disease (EMPD)] and the stomach (gastric cancer), we show that MUC5AC expression is reduced in COL4 and membranous E-cadherin-expressing EMPD specimens whereas MUC5AC is not abolished in gastric cancer with COL4 negativity and E-cadherin cytoplasmic localization. As the EMPD and gastric cancer specimens were derived from a single patient, each specimen had the same genetic background. These in vivo results support previous in vitro studies which showed that COL4 and E-cadherin downregulated MUC5AC expression."

According to the news reporters, the research concluded: "Our study suggests that concomitant neoplasms in different organs of the same individual can serve as a strong tool for uncovering functional diversity in tumor markers in distinct cancer cells."

Our news correspondents report that additional information may be obtained by contacting H. Hata, Dept. of Dermatology, Hokkaido University Graduate School of Medicine, N15 W7, Kita-ku, Sapporo, 060-8638, Japan. Additional authors for this research include K.

Drugs and Therapies - Antiinfectives

Researchers from Hospital Clinic Report Details of New Studies and Findings in the Area of Antiinfectives (Genomic and in silico analyses of CRBN gene and thalidomide embryopathy in humans)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Drugs and Therapies - Antiinfectives have been published. According to news originating from Porto Alegre, Brazil, by NewsRx correspondents, research stated, "Thalidomide causes Thalidomide Embryopathy (TE), but is largely used to treat several conditions. Investigations with Cereblon, a thalidomide target protein encoded by CRBN gene, have helped to understand thalidomide therapeutic and teratogenic properties."

Funders for this research include INAGEMP, FIPE/HCPA.

Our news journalists obtained a quote from the research from Hospital Clinic, "We sequenced CRBN-thalidomide binding region in 38 TE individuals and 136 Brazilians without congenital anomalies, and performed in silico analyses. Eight variants were identified, seven intronic and one in 3' UTR. TE individuals had rare variants in higher frequency than the non-affected group (p = 0.04). The genotype rsl 620675 CC was related to neurological anomalies in TE individuals (p = 0.004). Bioinformatics analysis suggested this genotype leads to potential alterations in splicing sites and binding to transcription factors. Comparison of the Cereblon-thalidomide binding domains in mammals demonstrated that CRBN is highly conserved across species."

According to the news editors, the research concluded: "All the variants require evaluation in functional assays in order to understand their role in Cereblon-thalidomide binding and complex interactions that lead to TE."

For more information on this research see: Genomic and in silico analyses of CRBN gene and thalidomide embryopathy in humans. Reproductive Toxicology, 2016;66():99-106. Reproductive Toxicology can be contacted at: Pergamon-Elsevier Science Ltd, The Boulevard, Langford Lane, Kidlington, Oxford OX5 1GB, England. (Elsevier - www.elsevier.com; Reproductive Toxicology - www.journals.elsevier.com/reproductive-toxicology/)

Researchers from Hospital del Mar Describe Findings in Hypertension (Renal volume and cardiovascular risk assessment in normotensive autosomal dominant polycystic kidney disease patients)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Cardiovascular Diseases and Conditions - Hypertension is the subject of a report. According to news reporting originating from Barcelona, Spain, by NewsRx correspondents, research stated, "Cardiovascular disease, closely related to an early appearance of hypertension, is the most common mortality cause among autosomal dominant polycystic kidney disease patients (ADPKD). The development of hypertension is related to an increase in renal volume."

Our news editors obtained a quote from the research from Hospital del Mar, "Whether the increasing in the renal volume before the onset of hypertension leads to a major cardiovascular risk in ADPKD patients remains unknown. Observational and cross-sectional study of 62 normotensive ADPKD patients with normal renal function and a group of 28 healthy controls. Renal volume, blood pressure, and renal (urinary albumin excretion), blood vessels (carotid intima media thickness and carotid-femoral pulse wave velocity), and cardiac (left ventricular mass index and diastolic dysfunction parameters) asymptomatic organ damage were determined and were considered as continuous variables. Correlations between renal volume and the other parameters were studied in the ADPKD population, and results were compared with the control group. Blood pressure values and asymptomatic organ damage were used to assess the cardiovascular risk according to renal volume tertiles. Even though in the normotensive range, ADPKD patients show higher blood pressure and major asymptomatic organ damage than healthy controls. Asymptomatic organ damage is not only related to blood pressure level but also to renal volume. Multivariate regression analysis shows that microalbuminuria is only associated with height adjusted renal volume (htTKV). An htTKV above 480 mL/m represents a 10 times higher prevalence of microalbuminuria (4.8% vs 50%, P <0.001). Normotensive ADPKD patients from the 2nd tertile renal volume group (htTKV > 336mL/m) show higher urinary albumin excretion, but the 3rd tertile htTKV (htTKV > 469mL/m) group shows the worst cardiovascular risk profile. Normotensive ADPKD patients show in the early stages of the disease with slight increase in renal volume, higher cardiovascular risk than healthy controls. An htTKV above 468mL/m is associated with the greatest increase in cardiovascular risk of normotensive ADPKD patients with normal renal function."

According to the news editors, the research concluded: "Early strategies to slow the
progression of the cardiovascular risk of these patients might be beneficial in their long-term cardiovascular survival."

For more information on this research see: Renal volume and cardiovascular risk assessment in normotensive autosomal dominant polycystic kidney disease patients. *Medicine*, 2016;95(49):542-548. *Medicine* can be contacted at: Lippincott Williams & Wilkins, Two Commerce Sq, 2001 Market St, Philadelphia, PA 19103, USA. **Drugs and Therapies - Chemotherapy**

**Researchers from Hospital of Santa Maria Discuss Findings in Chemotherapy (2016 updated MASCC/ESMO consensus recommendations: Prevention of nausea and vomiting following moderately emetogenic chemotherapy)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Drugs and Therapies - Chemotherapy. According to news originating from Terni, Italy, by NewsRx correspondents, research stated, "An update of the recommendations for the prophylaxis of acute and delayed emesis induced by moderately emetogenic chemotherapy published after the last MASCC/ESMO antiemetic consensus conference in 2009 has been carried out. A systematic literature search using PubMed from January 1, 2009 to January 6, 2015 with a restriction to papers in English was conducted."

Financial support for this research came from ESMO MASCC.

Our news journalists obtained a quote from the research from the Hospital of Santa Maria, "Overall, two randomized phase II and seven randomized phase III studies plus the results of three subgroup analysis of large phase III trials and those of a pilot study have been included. In carboplatin-treated patients, a moderate benefit from adding an NK1 receptor antagonist to dexamethasone and a 5-HT3 receptor antagonist has been shown. However, in oxaliplatin-treated patients, contrasting results about the role of NK1 receptor antagonists have been obtained. At present, it is not possible to suggest a specific 5-HT3 receptor antagonist to use for the prevention of acute emesis in these patients."

According to the news editors, the research concluded: "No routine prophylaxis for delayed emesis is recommended but in patients receiving moderately emetogenic chemotherapy with known potential for delayed emesis (e.g., oxaliplatin, doxorubicin, cyclophosphamide) the use of dexamethasone for days 2-3 can be considered."

For more information on this research see: 2016 updated MASCC/ESMO consensus recommendations: Prevention of nausea and vomiting following moderately emetogenic
chemotherapy. Supportive Care in Cancer, 2017;25(1):289-294. Supportive Care in Cancer can be contacted at: Springer, 233 Spring St, New York, NY 10013, USA. (Springer - www.springer.com; Supportive Care in Cancer - www.springerlink.com/content/0941-4355/)

Drugs and Therapies - Drug Delivery Systems

Researchers from Huazhong University of Science and Technology Provide Details of New Studies and Findings in the Area of Drug Delivery Systems (Shear Stress-sensitive Carriers for Localized Drug Delivery)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Drugs and Therapies - Drug Delivery Systems are discussed in a new report. According to news originating from Wuhan, People’s Republic of China, by NewsRx correspondents, research stated, "Stenosis of the critical blood vessels, which occurs in a variety of cardiovascular and cerebrovascular diseases, is one of leading causes of death in the world. Vascular stenosis will significantly alter the hemodynamic features in the vessel."

Our news journalists obtained a quote from the research from the Huazhong University of Science and Technology, "Hemodynamic shear stress, one of the most important physical parameters of blood flow, will be dramatically elevated at the stenotic site. When platelets flow through the constricted site, they will sense these abnormally high shear stresses, and then respond by activating, sticking to the vascular wall, and aggregating at these sites. The shear-dependent platelet activation inspired a novel targeting platform-shear stress activated drug targeting delivery. The shear-activated drug delivery systems preferentially release their content under elevated shear stress, providing a novel approach to cure various diseases, in particular, cardiovascular diseases. In this review, we, on one hand, introduced the features of hemodynamic shear stress under both physiological and pathological conditions. On the other hand, we summarized the carriers displaying sensitivity to shear stress, such as liposomes, aggregations, gels, emulsions, in addition to the factors affecting the mechanical properties of them. Lastly, the clinical applications and prospects of this novel drug targeting strategy were discussed."

According to the news editors, the research concluded: "It is hoped that, with a better understanding of shear stress-sensitive carriers and their targeted principle, a novel targeted drug delivery strategy will be one day applied in the clinics of the future."

For more information on this research see: Shear Stress-sensitive Carriers for

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.2174/1381612822666160628081419. This DOI is a link to an online electronic document that is either free or for purchase.

**Oncology - Carcinomas**

**Researchers from Huazhong University of Science and Technology Report Details of New Studies and Findings in the Area of Carcinomas (HSP27 Knockdown Increases Cytoplasmic p21 and Cisplatin Sensitivity in Ovarian Carcinoma Cells)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Oncology - Carcinomas have been published. According to news reporting out of Hubei, People's Republic of China, by NewsRx editors, research stated, "Drug resistance is the leading cause of chemotherapy failure in the treatment of ovarian cancer. So far, little is known about the mechanism of chemoresistance in ovarian cancer."

Our news journalists obtained a quote from the research from the Huazhong University of Science and Technology, "In this study, we explored the mechanism that HSP27 was involved in cisplatin resistance of ovarian cancer both in vitro and clinically. HSP27 protein was found to be upregulated and expressed in cisplatin-resistant ovarian cancer cell line C13*, and HSP27 siRNA transfection reversed the chemoresistance of C13*. We found that HSP27 exerted its chemoresistant role by inhibiting p21 transferring from the nucleus to the plasma through the activation of phosphorylated-Akt pathway."

According to the news editors, the research concluded: "These findings have implications for clinical trials aimed at a potential therapeutic target for ovarian tumors that are refractory to conventional treatment."

Our news journalists report that additional information may be obtained by contacting H. Lu, Cancer Biology Medical Centre, Tongji Hospital, Tongji Medical College,
Researchers from Huazhong University of Science and Technology

 Liver Diseases and Conditions - Hepatitis B Virus

Report Recent Findings in Hepatitis B Virus [Multidrug resistance protein 4 is a critical protein associated with the antiviral efficacy of nucleos(t)ide analogues]

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Liver Diseases and Conditions - Hepatitis B Virus is now available. According to news reporting originating in Wuhan, People's Republic of China, by NewsRx journalists, research stated, "Multidrug resistance protein 4 (MRP4) has been associated with nucleos(t)ide analogue (NA) antiretroviral therapy failure, though is unclear if MRP4 is also correlated with the failure of anti-hepatitis B virus (HBV) therapy. Multidrug resistance protein 4 expression in human peripheral blood mononuclear cells (PBMCs), liver tissues and human hepatoma cell lines was detected by real-time polymerase chain reaction (PCR), western blotting and immunohistochemistry assays."

Financial support for this research came from National Natural Science Foundation of China.

The news reporters obtained a quote from the research from the Huazhong University of Science and Technology, "Supernatant and intracellular HBV DNA levels of MRP4-overexpressing or silenced HepG2.4D14 (wild-type) and HepG2.A64 (entecavir-resistant mutant) cells were measured by quantitative PCR. NA concentrations and HBV mutational analysis were assessed by liquid chromatography/mass spectrometry assays and DNA sequencing. Multivariate analysis was used to assess predictive factors for treatment failure. High expression of MRP4 was found in hepatoma cell lines and PBMCs, and up-or down-regulation of MRP4 expression altered the susceptibility of cells to NAs. MRP inhibitors increased NA intracellular accumulation and decreased extracellular levels. Moreover, MRP4 expression in PBMCs was correlated with that in paired liver tissues. Furthermore, multivariate analysis showed MRP4 mRNA expression to be an independent predictor of NA treatment failure. Multidrug resistance protein 4 is a critical protein associated with the antiviral efficacy of NAs, and combination therapy of NA and MRP inhibitors could reduce the dosage for long-term NA use."

According to the news reporters, the research concluded: "This is the first report to demonstrate that MRP4 expression is an important factor predicting treatment failure in chronic..."
hepatitis B patients and will provide a potential therapeutic target against HBV.

Our news correspondents report that additional information may be obtained by contacting X. Zheng, Huazhong University of Science & Technology, Tongji Med College, Union Hosp, Dept. of Infect Dis, Wuhan 430022, People's Republic of China. Additional authors for this research include H.X. Song, Q. Chen, C.L. Xu, W.J. Zhang, Y.T. Liu, B.J. Wang, D.P. Xu, M.J. Lu, D.L. Yang and X. Zheng.

Influenza A Virus Subtype H1N1

Researchers from Hunan Normal University Report on Findings in Influenza A Virus Subtype H1N1 (Computational screen and experimental validation of anti-influenza effects of quercetin and chlorogenic acid from traditional Chinese medicine)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Influenza A Virus Subtype H1N1. According to news reporting originating from Changsha, People's Republic of China, by NewsRx correspondents, research stated, "The Influenza A virus is a great threat for human health, while various subtypes of the virus made it difficult to develop drugs. With the development of state-of-art computational chemistry, computational molecular docking could serve as a virtual screen of potential leading compound."

Our news editors obtained a quote from the research from Hunan Normal University, "In this study, we performed molecular docking for influenza A H1N1 (A/PR/8/34) with small molecules such as quercetin and chlorogenic acid, which were derived from traditional Chinese medicine. The results showed that these small molecules have strong binding abilities with neuraminidase from H1N1 (A/PR/8/34). Further details showed that the structural features of the molecules might be helpful for further drug design and development. The experiments in vitro, in vivo have validated the anti-influenza effect of quercetin and chlorogenic acid, which indicating comparable protection effects as zanamivir."

According to the news editors, the research concluded: "Taken together, it was proposed that chlorogenic acid and quercetin could be employed as the effective lead
compounds for anti-influenza A H1N1."

For more information on this research see: Computational screen and experimental validation of anti-influenza effects of quercetin and chlorogenic acid from traditional Chinese medicine. *Scientific Reports*, 2016;6():19095. Oncology - Cancer Imaging

Researchers from Hunan University Report New Studies and Findings in the Area of Cancer Imaging (Nature-Inspired Smart DNA Nanodoctor for Activatable In Vivo Cancer Imaging and In Situ Drug Release Based on Recognition-Triggered Assembly of ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Oncology - Cancer Imaging have been published. According to news originating from Changsha, People's Republic of China, by NewsRx correspondents, research stated, "DNA-based activatable theranostic nanoprobes are still unmet for in vivo applications. Here, by utilizing the 'induced-fit effect', a smart split aptamer-based activatable theranostic probe (SATP) was first designed as 'nanodoctor' for cancer-activated in vivo imaging and in situ drug release."

Financial supporters for this research include National Natural Science Foundation of China, Natural Science Foundation of Hunan Province.

Our news journalists obtained a quote from the research from Hunan University, "The SATP assembled with quenched fluorescence and stable drug loading in its free state. Once binding to target proteins on cell surface, the SATP disassembled due to recognition-triggered reassembly of split aptamers with activated signals and freed drugs. As proof of concept, split Sgc8c against CEM cancer was used for theranostic studies. Benefiting from the design without blocking aptamer sequence, the SATP maintained an excellent recognition ability similar to intact Sgc8c. An ‘incubate-and-detect’ assay showed that the SATP could significantly lower background and improve signal-to-background ratio (similar to 4.8 times of ‘always on’ probes), thus affording high sensitivity for CEM cell analysis with 46 cells detected. Also, its high selectivity to target cells was demonstrated in analyzing mixed cell samples and serum samples. Then, using doxorubicin as a model, highly specific drug delivery and cell killing was realized with minimized toxicity to nontarget cells. Moreover, in vivo and ex vivo
investigations also revealed that the SATP was specifically activated by CEM tumors inside mice. Especially, contrast enhanced imaging was achieved in as short as 5 min, thus, laying a foundation for rapid diagnosis and timely therapy."

According to the news editors, the research concluded: "As a biocompatible and target-activatable strategy, the SATP may be widely applied in cancer theranostics."

For more information on this research see: Nature-Inspired Smart DNA Nanodocor for Activatable In Vivo Cancer Imaging and In Situ Drug Release Based on Recognition-Triggered Assembly of Split Aptamer. Analytical Chemistry, 2016;88(23):11699-11706. Analytical Chemistry can be contacted at: Amer Chemical Soc, 1155 16TH St, NW, Washington, DC 20036, USA. Keywords for this news article include: Changsha, People's Republic of China, Asia, Cancer, Drugs and Therapies, Cancer Imaging, Oncology, Genetics, Hunan University.

Our news editors obtained a quote from the research from IRCSS, "This requires a deep understanding of the epigenetic mechanisms controlling transcriptional programs in tissue progenitors. This review attempts to elucidate the principle epigenetic regulations responsible of stem cells differentiation. In particular we focus on the current understanding of the epigenetic networks that regulate differentiation of muscle progenitors by the concerted action of chromatin-modifying enzymes and noncoding RNAs. The novel exciting role of exosome-bound microRNA in mediating epigenetic information transfer is also discussed."

According to the news editors, the research concluded: "Finally we show an overview of the epigenetic strategies and therapies that aim to potentiate muscle regeneration
and counteract the progression of Duchenne Muscular Dystrophy (DMD)."

For more information on this research see: Epigenetic Reprogramming of Muscle Progenitors: Inspiration for Clinical Therapies. *Stem Cells International*, 2015;2016():6093601. (Hindawi Publishing - www.hindawi.com; Stem Cells International - www.hindawi.com/journals/sci/)

**Oncology - Prostate Cancer**

**Researchers from Imperial College Detail Findings in Prostate Cancer (Diet, body size, physical activity and risk of prostate cancer: An umbrella review of the evidence)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Oncology - Prostate Cancer. According to news reporting originating in London, United Kingdom, by NewsRx journalists, research stated, "The existing literature on the relationship between diet, body size, physical activity and prostate cancer risk was summarised by the World Cancer Research Fund Continuous Update Project (CUP). An evaluation of the robustness of this evidence is required to help inform public health policy."

The news reporters obtained a quote from the research from Imperial College, "The robustness of this evidence was evaluated using several criteria addressing evidence strength and validity, including the statistical significance of the random effects summary estimate and of the largest study in a meta-analysis, number of prostate cancer cases, between-study heterogeneity, 95% prediction intervals, small-study effects bias, excess significance bias and sensitivity analyses with credibility ceilings. A total of 248 meta-analyses were extracted from the CUP, which studied associations of 23 foods, 31 nutrients, eight indices of body size and three indices of physical activity with risk of total prostate cancer development, mortality or cancer development by stage and grade. Of the 176 meta-analyses using a continuous scale to measure the exposures, no association presented strong evidence by satisfying all the aforementioned criteria. Only the association of height with total prostate cancer incidence and mortality presented highly suggestive evidence with a 4% higher risk per 5 cm greater height (95% confidence interval, 1.03, 1.05). Associations for body mass index, weight, height, dietary calcium and spirits intake were supported by suggestive evidence."

According to the news reporters, the research concluded: "Overall, the association of diet, body size, physical activity and prostate cancer has been extensively studied, but no association was graded with strong evidence."

Our news correspondents report that additional information may be obtained by contacting K.K. Tsilidis, Imperial Coll London, Dept. of Epidemiol & Biostat, Sch Public Hlth, London W2 1PG, United Kingdom. Additional authors for this research include I. Tzoulaki, D. Karli, E. Evangelou, E. Ntzani, M.J. Gunter, T. Norat, J.P. Ioannidis and K.K. Tsilidis.

**Immune System Diseases and Conditions - HIV/AIDS**

**Researchers from Imperial College Report Recent Findings in HIV/AIDS (How do HIV-negative individuals in sub-Saharan Africa change their sexual risk behaviour upon learning their serostatus? A systematic review)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Immune System Diseases and Conditions - HIV/AIDS are presented in a new report. According to news reporting originating in London, United Kingdom, by NewsRx journalists, research stated, "To determine whether, and how, sexual behaviour of HIV-negative individuals in sub-Saharan Africa (SSA) changes upon learning their serostatus. We systematically reviewed the published literature using EMBASE and Medline to search for publications between 2004 and 2014."

The news reporters obtained a quote from the research from Imperial College, "We included studies that quantified behaviour change (condom use, number of sexual partners or sex acts) following an HIV test in HIV-negative adults in SSA, and extracted relevant data including study characteristics and measurement type. From 2185 unique citations, n=14 studies representing 22 390 participants met our inclusion criteria. We did not pool data due to marked heterogeneity in study outcome measures. The proportion of participants reporting consistent condom use (n=6) post-testing ranged from 7.6% greater, to 10.6% fewer, while 'no condom use' (n=5) ranged from 40.0% less, to 0.7% more. Condom use in serodiscordant couples increased (n=3). Five studies measured the proportion reporting abstinence, finding an increase of 10.9% to a decrease of 5.3% post-testing. The post-testing change in the mean number of sex acts (n=3) ranged from a relative decrease of 15.7% to a relative increase of 9.4%. Two studies reported relative decreases in the mean number of sexual partners of 35.2% and 14.0%. Three studies examining serodiscordant primary relationships specifically all showed increases in extrarelational sex. With the exception of serodiscordant couples, there is variable evidence that awareness of one's serostatus leads to substantial changes in risk behaviour among HIV-negative individuals."

According to the news reporters, the research concluded: "Further research is needed to estimate the behavioural impact of learning one's serostatus in SSA."
For more information on this research see: How do HIV-negative individuals in sub-Saharan Africa change their sexual risk behaviour upon learning their serostatus? A systematic review. *Sexually Transmitted Infections*, 2016;92(8):571-578. *Sexually Transmitted Infections* can be contacted at: Bmj Publishing Group, British Med Assoc House, Tavistock Square, London WC1H 9JR, England. **Oncology - Colon Cancer**

Researchers from Indian Institute of Chemical Biology Report on Findings in Colon Cancer (DNA damage-induced ephrin-B2 reverse signaling promotes chemoresistance and drives EMT in colorectal carcinoma harboring mutant p53)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Oncology - Colon Cancer have been presented. According to news reporting out of Kolkata, India, by NewsRx editors, research stated, "Mutation in the TP53 gene positively correlates with increased incidence of chemoresistance in different cancers. In this study, we investigated the mechanism of chemoresistance and epithelial-to-mesenchymal transition (EMT) in colorectal cancer involving the gain-of-function (GOF) mutant p53/ephrin-B2 signaling axis."

Our news journalists obtained a quote from the research from the Indian Institute of Chemical Biology, "Bioinformatic analysis of the NCI-60 data set and subsequent hub prediction identified EFNB2 as a possible GOF mutant p53 target gene, responsible for chemoresistance. We show that the mutant p53-NF-Y complex transcriptionally upregulates EFNB2 expression in response to DNA damage. Moreover, the acetylated form of mutant p53 protein is recruited on the EFNB2 promoter and positively regulates its expression in conjunction with coactivator p300. In vitro cell line and in vivo nude mice data show that EFNB2 silencing restores chemosensitivity in mutant p53-harboring tumors. In addition, we observed high expression of EFNB2 in patients having neoadjuvant non-responder colorectal carcinoma compared with those having responder version of the disease. In the course of deciphering the drug resistance mechanism, we also show that ephrin-B2 reverse signaling induces ABCG2 expression after drug treatment that involves JNK-c-Jun signaling in mutant p53 cells. Moreover, 5-fluorouracil-induced ephrin-B2 reverse signaling promotes tumorigenesis through the Src-ERK pathway, and drives EMT via the Src-FAK pathway."
According to the news editors, the research concluded: "We thus conclude that targeting ephrin-B2 might enhance the therapeutic potential of DNA-damaging chemotherapeutic agents in mutant p53-bearing human tumors."

For more information on this research see: DNA damage-induced ephrin-B2 reverse signaling promotes chemoresistance and drives EMT in colorectal carcinoma harboring mutant p53. *Cell Death and Differentiation*, 2015;23(4):707-22. **Congenital Diseases and Conditions - Congenital...**

**Researchers from Indiana University Detail New Studies and Findings in the Area of Congenital Heart Defects (A Three-Way Interaction among Maternal and Fetal Variants Contributing to Congenital Heart Defects)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Congenital Diseases and Conditions - Congenital Heart Defects is the subject of a report. According to news reporting from Bloomington, Indiana, by NewsRx journalists, research stated, "Congenital heart defects (CHDs) develop through a complex interplay between genetic variants, epigenetic modifications, and maternal environmental exposures. Genetic studies of CHDs have commonly tested single genetic variants for association with CHDs."

Funders for this research include National Institute of Child Health and Human Development, National Center on Birth Defects and Developmental Disabilities, Translational Research Institute through the NIH National Center for Research Resources and the National Center for Advancing Translational Sciences, University of Arkansas for Medical Sciences College of Medicine Children's University Medical Group Fund Grant Program, Arkansas Children’s Hospital Research Institute and the Arkansas Bioscience Institute.

The news correspondents obtained a quote from the research from Indiana University, "Less attention has been given to complex gene-by-gene and gene-by-environment interactions. In this study, we applied a recently developed likelihood-ratio Mann-Whitney (LRMW) method to detect joint actions among maternal variants, fetal variants, and maternal environmental exposures, allowing for high-order statistical interactions. All subjects are
participants from the National Birth Defect Prevention Study, including 623 mother-offspring pairs with CHD-affected pregnancies and 875 mother-offspring pairs with unaffected pregnancies. Each individual has 872 single nucleotide polymorphisms encoding for critical enzymes in the homocysteine, folate, and trans-sulfuration pathways. By using the LRMW method, three variants (fetal rs625879, maternal rs2169650, and maternal rs8177441) were identified with a joint association to CHD risk (nominal P-value=1.13e-07). These three variants are located within genes BHMT2, GSTP1, and GPX3, respectively. Further examination indicated that maternal SNP rs2169650 may interact with both fetal SNP rs625879 and maternal SNP rs8177441.

According to the news reporters, the research concluded: "Our findings suggest that the risk of CHD may be influenced by both the intragenerational interaction within the maternal genome and the intergenerational interaction between maternal and fetal genomes."

Oncology - Breast Cancer

Researchers from Institut Universitaire de France Discuss Findings in Breast Cancer (SCN4B acts as a metastasis-suppressor gene preventing hyperactivation of cell migration in breast cancer)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Oncology - Breast Cancer. According to news reporting originating in Paris, France, by NewsRx journalists, research stated, "The development of metastases largely relies on the capacity of cancer cells to invade extracellular matrices (ECM) using two invasion modes termed 'mesenchymal' and 'amoeboid', with possible transitions between these modes. Here we show that the SCN4B gene, encoding for the beta 4 protein, initially characterized as an auxiliary subunit of voltage-gated sodium channels (Na-V) in excitable tissues, is expressed in normal epithelial cells and that reduced beta 4 protein levels in breast cancer biopsies correlate with high-grade primary and metastatic tumours."
The news reporters obtained a quote from the research from Institut Universitaire de France, "In cancer cells, reducing b4 expression increases RhoA activity, potentiates cell migration and invasiveness, primary tumour growth and metastatic spreading, by promoting the acquisition of an amoeboid-mesenchymal hybrid phenotype. This hyperactivated migration is independent of NaV and is prevented by overexpression of the intracellular C-terminus of b4."

According to the news reporters, the research concluded: "Conversely, SCN4B overexpression reduces cancer cell invasiveness and tumour progression, indicating that SCN4B/beta 4 represents a metastasis-suppressor gene."

Our news correspondents report that additional information may be obtained by contacting S. Roger, Inst Univ France, F-75231 Paris 05, France. Additional authors for this research include V. Driffort, F. Gradek, C. Martinez-Caceres, M. Anchelin, P. Pelegrin, M.L. Cayuela, S. Marionneau-Lambot, T. Oullier, R. Guibon, G. Fromont, J.L. Gutierrez-Pajares, I. Domingo, E. Piver, A. Moreau, J. Burlaud-Gaillard and P.G Frank.

Researchers from Institute for Cancer Research and Treatment (IRCCS) Provide Details of New Studies and Findings in the Area of Blood Pressure (Threshold and Target for Blood Pressure Lowering in the Elderly)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Blood Pressure is the subject of a report. According to news reporting originating from Milan, Italy, by NewsRx correspondents, research stated, "Purpose of Review Detection of elevated blood pressure values in elderly patients represents a common clinical condition associated with an increased cardiovascular risk. This has been shown to be the case in both systodiastolic and isolated systolic hypertension as well."

Our news editors obtained a quote from the research from Institute for Cancer Research and Treatment (IRCCS), "However, despite the evidence of the benefits of the blood pressure lowering intervention in terms of reduction of cardiovascular morbidity and mortality, at least two issues related to antihypertensive drug treatment in aged individuals are still undefined: (1) the blood pressure threshold at which antihypertensive drug should be initiated and (2) the blood pressure goals of the therapeutic intervention. The present paper will critically review the evidence available so far on these two issues as well as the position of current guidelines and consensus statements. Emphasis will be given to the analysis of the new data of the Systolic Blood Pressure Intervventional Trial (SPRINT), which have recently demonstrated the benefits, even in individuals aged more than 75 years, of a tight blood pressure reduction to systolic blood pressure to 120 mmHg or less. The potential limitations of the trial will be also
critically addressed and the expectations of ongoing clinical studies investigating the issue in elderly patients properly emphasized. Although of interest, the results of the SPRINT trial encompass a number of limitations which limit their applicability to the general elderly hypertensive population."

According to the news editors, the research concluded: "A prudent approach will be to adopt in clinical practice the less intensive and more conservative targets recommended by current guidelines."

For more information on this research see: Threshold and Target for Blood Pressure Lowering in the Elderly. Current Atherosclerosis Reports, 2016;18(12):17-27. Current Atherosclerosis Reports can be contacted at: Current Medicine Group, 400 Market Street, Ste 700, Philadelphia, PA 19106, USA. (Springer - www.springer.com; Current Atherosclerosis Reports - www.springerlink.com/content/1523-3804/)

Heart Disorders and Diseases - Heart Failure

Researchers from Institute for Medical Research Describe Findings in Heart Failure (Meta-Analysis of Association Between Mediastinal Radiotherapy and Long-Term Heart Failure)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Heart Disorders and Diseases - Heart Failure have been published. According to news reporting originating in Hobart, Australia, by NewsRx journalists, research stated, "This investigation sought to identify and quantify any increased risk of long-term heart failure (HF) after thoracic radiotherapy (RT) for cancer and identify any population covariates that corresponded with increased risk. Electronic databases were systematically searched for studies reporting relative risk, odds ratio, and hazard ratio (HR) for symptomatic HF more than 5 years after RT administration."

The news reporters obtained a quote from the research from Institute for Medical Research, "Clinical characteristics, study design, univariable effect sizes, and associated 95% CIs were extracted. Univariable effect size was pooled and computed in a meta-analysis using random-effects model weighted by inverse variance. Six studies (45,669 patients) with weighted median follow-up duration of 13.9 years were included, each data-linkage study that reported HRs for HF. Pooled HR for long-term HF was significant (HR 1.83 [1.09 to 3.08], p = 0.022), with significant between study heterogeneity (Q 43.38, df = 5, p<0.001, I-2 88.47%). Statistical significance was lost when excluding studies of malignancies other than breast cancer or hematological malignancies and excluding studies with Newcastle-Ottawa scores <8, but the direction of effect and magnitude remained approximately the same. Subgroup and meta-regression analyses demonstrated that study differences in age at time of RT administration and duration of follow-up explained approximately 80% of observed heterogeneity. Earlier
publication date was associated with increased HF risk. Other variables, including female proportion, proportion of adjuvant chemotherapy use, and sample size did not significantly impact the conclusions."

According to the news reporters, the research concluded: "RT approximately doubled the long-term risk of HF. This finding was associated with younger age at time of RT and longer follow-up duration, which explained approximately 80% of interstudy heterogeneity."

Our news correspondents report that additional information may be obtained by contacting M.T. Nolan, Menzies Inst Med Res, Cardiometab Res Unit, Hobart, Tas, Australia. Additional authors for this research include D.J. Russell, K. Negishi and T.H. Marwick.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1016/j.amjcard.2016.08.050. This DOI is a link to an online electronic document that is either free or for purchase.

Drugs and Therapies - Chemical Biology and Drug... Researchers from Institute of Bioorganic Chemistry and Petrochemistry Describe Findings in Chemical Biology and Drug Design (A New, Improved Hybrid Scoring Function for Molecular Docking and Scoring Based on AutoDock and AutoDock Vina)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Drugs and Therapies - Chemical Biology and Drug Design. According to news reporting out of Kyiv, Ukraine, by NewsRx editors, research stated, "Automated docking is one of the most important tools for structure-based drug design that allows prediction of ligand binding poses and also provides an estimate of how well small molecules fit in the binding site of a protein. A new scoring function based on AutoDock and AutoDock Vina has been introduced."

Funders for this research include National Academy of Sciences of Ukraine to the Institute of Bioorganic Chemistry and Petrochemistry, Ontario Institute for Cancer Research, Government of Ontario.

Our news journalists obtained a quote from the research from the Institute of Bioorganic Chemistry and Petrochemistry, "The new hybrid scoring function is a linear combination of the two scoring function components derived from a multiple linear regression fitting procedure. The scoring function was built on a training set of 2412 protein-ligand complexes from pdbbind database (www.pdbbind.org.cn, version 2012). A test set of 313
complexes that appeared in the 2013 version was used for validation purposes. The new hybrid scoring function performed better than the original functions, both on training and test sets of protein-ligand complexes, as measured by the non-parametric Pearson correlation coefficient, R, mean absolute error (MAE), and root-mean-square error (RMSE) between the experimental binding affinities and the docking scores. The function also gave one of the best results among more than 20 scoring functions tested on the core set of the pdbbind database."

According to the news editors, the research concluded: "The new AutoDock hybrid scoring function will be implemented in modified version of AutoDock."

Our news journalists report that additional information may be obtained by contacting V.Y. Tanchuk, Dept. of Bioorganic Mechanisms, Institute of Bioorganic Chemistry and Petrochemistry, National Academy of Sciences of Ukraine, 1 Murmanska Street-94, Kyiv, 02660, Ukraine. Additional authors for this research include V.O. Tanin, A.I. Vovk and G. Poda.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1111/cbdd.12697. This DOI is a link to an online electronic document that is either free or for purchase.

**Transverse Aortic Constriction**

**Researchers from Institute of Health Sciences Discuss Findings in Transverse Aortic Constriction (Ascending aortic adventitial remodeling and fibrosis are ameliorated with Apelin-13 in rats after TAC via suppression of the miRNA-122 and ...)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Transverse Aortic Constriction have been presented. According to news originating from Shanghai, People's Republic of China, by NewsRx correspondents, research stated, "Apelin has been proved to be a critical mediator of vascular function and homeostasis. Here, we investigated roles of Apelin in aortic remodeling and fibrosis in rats with transverse aortic constriction (TAC)."

Our news journalists obtained a quote from the research from the Institute of Health Sciences, "Male Sprague-Dawley rats were subjected to TAC and then randomized to daily deliver Apelin-13 (50 μg/kg) or angiotensin type 1 receptor (AT1) blocker Irbesartan (50 mg/kg) for 4 weeks. Pressure overload resulted in myocardial hypertrophy, systolic dysfunction, aortic remodeling and adventitial fibrosis with reduced levels of Apelin in ascending aortas of..."
rat after TAC compared with sham-operated group. These changes were associated with marked increases in levels of miRNA-122, TGF beta 1, CTGF, NFAT5, LGR4, and beta-catenin. More importantly, Apelin and Irbesartan treatment strikingly prevented TAC-mediated aortic remodeling and adventitial fibrosis in pressure overloaded rats by blocking AT1 receptor and miRNA-122 levels and repressing activation of the CTGF-NFAT5 and LGR4-beta-catenin signaling. In cultured primary rat adventitial fibroblasts, exposure to angiotensin II (100 nmol L-1) led to significant increases in cellular migration and levels of TGFI31, CTGF, NFAT5, LGR4 and beta-catenin, which were effectively reversed by pre-treatment with Apelin (100 nmol L-1) and miRNA-122 inhibitor (50 nmol L-1)."

According to the news editors, the research concluded: "Apelin counterregulated against TAC-mediated ascending aortic remodeling and angiotensin II-induced promotion of cellular migration by blocking AT1 receptor and miRNA-122 levels and preventing activation of the TGF beta 1-CTGF-NFAT5 and LGR4-beta-catenin signaling, ultimately contributing to attenuation of aortic adventitial fibrosis. Our data point to Apelin as an important regulator of aortic remodeling and adventitial fibrosis and a promising target for vasoprotective therapies."

For more information on this research see: Ascending aortic adventitial remodeling and fibrosis are ameliorated with Apelin-13 in rats after TAC via suppression of the miRNA-122 and LGR4-beta-catenin signaling. Peptides, 2016;86():85-94. Peptides can be contacted at: Elsevier Science Inc, 360 Park Ave South, New York, NY 10010-1710, USA. Genetics, "We recently identified several miRNAs that either increased or decreased intermediate-term memory when inhibited in the central nervous system, including miR-iab8-3p. We report here a new developmental role for this miRNA. Blocking the expression of miR-iab8-3p during the development of the organism leads to hypertrophy of individual mushroom body neuron soma, a reduction in the field size occupied by axonal projections, and adult intellectual disability. We further identified four potential mRNA targets of miR-iab8-3p whose inhibition modulates intermediate term memory including ceramide phosphoethanolamine synthase, which may account for the behavioral effects produced by miR-iab8-3p inhibition."

According to the news editors, the research concluded: "Our results offer important new information on a microRNA required for normal neurodevelopment and the capacity to learn and remember normally."

For more information on this research see: Developmental inhibition of miR-iab8-3p disrupts mushroom body neuron structure and adult learning ability. Developmental Biology, 2016;419(2):237-249. Oncology - Cancer Genetics

Researchers from Institute of Medicine Report Findings in Cancer Genetics [A der(11)t(4;11)(q21;p15) in a T-ALL/LBL patient]

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Oncology - Cancer Genetics are presented in a new report. According to news originating from Buenos Aires, Argentina, by NewsRx correspondents, research stated, "Translocation t(4;11)(q21;p15) is a rare recurrent change associated to T-cell acute leukemia. In most cases, this alteration appears as the only abnormality or as part of a simple karyotype."

Financial supporters for this research include National Research Council, National Agency of Scientific and Technical Promotion, National Cancer Institute from Argentina.

Our news journalists obtained a quote from the research from the Institute of Medicine, "In this report, we present the first case of T acute lymphoblastic leukemia/lymphoma (T-ALL/LBL) with the unbalanced translocation der(11)t(4;11)(q21;p15) as part of a very complex karyotype with multiple chromosome abnormalities, most of them not previously described in the literature. FISH (fluorescence in situ hybridization) and spectral karyotype
(HiSKY) analysis confirmed the presence of complex alterations. The patient, a 16-year-old male, showed poor response to treatment and short survival (11 months). A detailed review of previously reported cases with t(4;11)(q21;p15) is also provided.

According to the news editors, the research concluded: "The description of this type of alterations may contribute to the identification of new molecular mechanism associated to neoplastic development."

The news correspondents report that additional information may be obtained from I. Slavutsky, CONICET Academy Nacl Med, Inst Med Expt, Lab Genet Neoplasias Linfoides, Buenos Aires, DF, Argentina. Additional authors for this research include L. Furforo, E.R. Pisarello, M. Maidana, C. Martin, J. Bordone and I. Slavutsky.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1016/j.cancergen.2016.01.001. This DOI is a link to an online electronic document that is either free or for purchase.

**Drugs and Therapies - Phytotherapy**

*Researchers from Institute of Medicine Report New Studies and Findings in the Area of Phytotherapy (In Vitro Assessment of Plants Growing in Cuba Belonging to Solanaceae Family Against Leishmania amazonensis)*

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Drugs and Therapies - Phytotherapy have been published. According to news reporting originating in Habana, Cuba, by NewsRx journalists, research stated, "In this study, an in vitro antileishmanial assessment of plant extracts from 12 genera and 46 species growing in Cuba belonging to Solanaceae family was performed. A total of 226 extracts were screened against promastigotes of Leishmania amazonensis, and cytotoxicity of active extracts [median inhibitory concentration (IC50) promastigotes < 100 μg/mL] was determined on peritoneal macrophage from BALB/c mice."

The news reporters obtained a quote from the research from the Institute of Medicine, "Extracts that showed selective index > 5 were then assayed against intracellular amastigote. Metabolomics analysis of promissory extracts was performed using chemical profile obtained by ultra performance liquid chromatography. Only 11 extracts (4.9%) from nine plants were selected as potentially actives: Brunfelsia cestroides A. Rich, Capsicum annuum L., Capsicum chinense Jacq., Cestrum nocturnum L., Nicotiana plumbaginifolia Viv., Solanum havanense Jacq., Solanum myriacanthum Dunal, Solanum nudum Dunal and Solanum seaforthianum And., with IC50 < 50 μg/mL and selectivity index > 5. Metabolomics analysis demonstrated significant differences in the chemical profiles with an average of 42.8 (range 31-88) compounds from m/z 104 to 1477, which demonstrated the complex mixture of compounds.
In addition, no common markers among active extracts were identified."

According to the news reporters, the research concluded: "The results demonstrate the importance of the Solanaceae family to search new antileishmanial agents, particularly in unexplored species of this family."

Our news correspondents report that additional information may be obtained by contacting L. Monzote, Inst Med Trop Pedro Kouri, Dept. of Parasitol, Marianao 13, Habana, Cuba. Additional authors for this research include J. Jimenez, O. Cuesta-Rubio, I. Marquez, Y. Gutierrez, C.Q. da Rocha, M. Marchi, W.N. Setzer and W. Vilegas.

---

**Biotechnology - Liposomes**

**Researchers from Institute of Physical Chemistry Report on Findings in Liposomes (Imidazolium-Based Lipid Analogues and Their Interaction with Phosphatidylycholine Membranes)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Biotechnology - Liposomes is the subject of a report. According to news originating from Munster, Germany, by NewsRx correspondents, research stated, "4,5-Dialkylated imidazolium lipid salts are a new class of lipid analogues showing distinct biological activities. The potential effects of the imidazolium lipids on artificial lipid membranes and the corresponding membrane interactions was analyzed."

Financial supporters for this research include Deutsche Forschungsgemeinschaft, Alexander von Humboldt-Stiftung, Fundacao para a Ciencia e a Tecnologia.

Our news journalists obtained a quote from the research from the Institute of Physical Chemistry, "Therefore, 1,2-dipalmitoyl-sn-glycero-3-phosphocholine (DPPC) was employed to create an established lipid monolayer model and a bilayer membrane. Mixed monolayers of DPPC and 4,5-dialkylimidazolium lipids differing by their alkyl chain length (C-7, C-11, and C-15) were characterized by surface pressure area (pi-A) isotherms using a Wilhelmy film balance in combination with epifluorescence microscopy. Monolayer hysteresis for binary mixtures was examined by recording triplicate consecutive compression expansion cycles. The lipid miscibility and membrane stability of DPPC/imidazolium lipids were subsequently evaluated by the excess mean molecular area (Delta A(ex)) and the excess Gibbs free energy (Delta G(ex)) of mixing. Furthermore, the thermotropic behavior of mixed liposomes of DPPC/imidazolium lipids was investigated by differential scanning calorimetry (DSC). The C-15-imidazolium lipid (C-15-IMe.HI) forms a thermodynamically favored and kinetically reversible Langmuir monolayer with DPPC and exhibits a rigidification effect on both DPPC monolayer and bilayer structures at low molar fractions (X <= 0.3). However, the
incorporation of the C-11-imidazolium lipid (C-11-Ime.HI) causes the formation of an unstable and irreversible Langmuir-Gibbs monolayer with DPPC and disordered DPPC liposomes. The C-7-imidazolium lipid (C-7-Ime.HI) displays negligible membrane activity. To better understand these results on a molecular level, all-atom molecular dynamics (MD) simulations were performed. The simulations yield two opposing molecular mechanisms governing the different behavior of the three imidazolium lipids: a lateral ordering effect and a free volume/stretching effect. Overall, our study provides the first evidence that the membrane interaction of the C-15 and C-11 derivatives modulates the structural organization of lipid membranes.

According to the news editors, the research concluded: "On the contrary, for the C-7 derivative its membrane activity is too low to contribute to its earlier reported potent cytotoxicity."

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1021/acs.langmuir.6b02496. This DOI is a link to an online electronic document that is either free or for purchase.

**Urologic Diseases and Conditions - Urinary...**

**Researchers from Institute of Urology Provide Details of New Studies and Findings in the Area of Urinary Incontinence (Urinary Incontinence Following Prostate Brachytherapy)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Urologic Diseases and Conditions - Urinary Incontinence is the subject of a report. According to news originating from Lake Success, New York, by NewsRx correspondents, research stated, "To define the incidence, time course, and risk factors associated with the development of urinary incontinence (UI) following prostate brachytherapy. A total of 2461 men were identified who underwent permanent interstitial prostate brachytherapy with or without external beam radiation therapy."

Our news journalists obtained a quote from the research from the Institute of Urology, "We examined the relationship between clinical-and treatment-related variables with the onset of UI, defined as leakage requiring pad usage, and further classified as stress (SUI) or urge (UUI) predominant, using univariate and Cox proportional hazards regression models. The changes in International Prostate Symptom Score and quality of life domains were assessed
from baseline to last follow, and examined by UI status. Patients were followed for a median of 6.4 years (interquartile range 4.1-9.3), UI was reported in 108 individuals (4.4%), at a median of 1.8 years (interquartile range 5 months-4.4 years): 30 with SUI and 78 with UUI. Seventy-two men (66.7%) reported using 1, 24 (22.2%) using 2, and 12 (11%) using >= 3 pads per day. On multivariate analysis, post-implantation transurethral resection of the prostate, urinary retention, external beam radiation therapy, and higher pretreatment International Prostate Symptom Score were significantly associated with the development of SUI, although transurethral resection of the prostate was the only significant risk factor associated with SUI. Men experiencing UI reported greater declines in urinary quality of life; however, no significant difference was observed between SUI and UUI. UI occurred in 4.4% of patients following prostate brachytherapy and is more commonly urge-predominant in character. Distinct risk factors exist for the development of UUI vs SUI.

According to the news editors, the research concluded: "Urinary leakage requiring pad usage was associated with declines in urinary QOL."

For more information on this research see: Urinary Incontinence Following Prostate Brachytherapy. Urology, 2016;95():151-157. Urology can be contacted at: Elsevier Science Inc, 360 Park Ave South, New York, NY 10010-1710, USA. (Elsevier - www.elsevier.com; Urology - www.journals.elsevier.com/urology/)

The news correspondents report that additional information may be obtained from S.J. Hall, Northwell Hlth Syst, Smith Inst Urol, Lake Success, NY 11042, United States. Additional authors for this research include N.N. Stone, S. Mock, R.G. Stock and S.J. Hall.

Oncology - Breast Cancer

Researchers from Isfahan University of Medical Sciences Detail Findings in Breast Cancer (Targeted delivery of doxorubicin to breast cancer cells by magnetic LHRH chitosan bioconjugated nanoparticles)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Oncology - Breast Cancer. According to news reporting from Esfahan, Iran, by NewsRx journalists, research stated, "The novel dual targeted nanoparticles loaded with doxorubicin (DOX) and magnetic nanoparticles (MNPs) were prepared for treatment of breast cancer. Nanoparticles were produced by a layer-by-layer technique and functionalized with a bioconjugate of chitosan-poly(methyl vinyl ether maleic acid)(PMVMA)-LHRH to target LHRH receptors."

Financial support for this research came from Research Vice Chancellor of Isfahan University of Medical Sciences.
The news correspondents obtained a quote from the research from the Isfahan University of Medical Sciences, "The successful production of chitosan-PMVMA copolymer and its conjugation to LHRH was confirmed by FTIR and (HNMR)-H-1 spectroscopy. Capillary electrophoresis analysis showed 72.51% LHRH conjugation efficiency. Transmission electron microscopy and thermogravimetric analysis showed the entrapment of the MNPs in the core of the nanoparticles and vibrating sample magnetometry confirmed their paramagnetic properties. The iron content of nanoparticles determined by inductively coupled plasma optical emission spectrometry showed to be between 3.5-84%. Particle size, zeta potential, drug entrapment and release efficiency of the nanoparticles were 88.1-182.6 nm, 10-30 mV, 62.3-87.6% and 79.8-83.4%, respectively. No significant protein binding was seen by nanoparticles. The MTT assay showed in LHRH positive cells of MCF-7 the IC50 of the drug reduced to about 2 fold compared to the free drug. By saturation of LHRH receptors the viable MCF7 cells increased significantly after exposure with the targeted nanoparticles."

According to the news reporters, the research concluded: "Therefore, the cellular uptake of the nanoparticles might be done by active endocytosis through the LHRH receptors."

Our news journalists report that additional information may be obtained by contacting J. Varshosaz, Isfahan Univ Med Sci, Novel Drug Delivery Syst Res Center, Esfahan, Iran. Additional authors for this research include F. Hassanzadeh, H.S. Aliabadi, F.R. Khoraskani, M. Mirian and B. Behdadfar.

### Hematologic Diseases and Conditions - Hemophilia

**Researchers from Istanbul University Detail New Studies and Findings in the Area of Hemophilia (Benefits of radial head excision in patients with haemophilia: mid-term functional results)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Hematologic Diseases and Conditions - Hemophilia have been presented. According to news reporting originating in Istanbul, Turkey, by NewsRx journalists, research stated, "Recurrent haemarthrosis in haemophilic patients result with arthropathy of the radiocapitellar joint and blockage of the forearm rotation. The aim of this
study is to evaluate the mid-term results of radial head excision with partial synovectomy in severe haemophilic patients retrospectively."

The news reporters obtained a quote from the research from Istanbul University, "Persistent pain and decreased forearm rotation were the main indications for radial head excision. Between 2002 and 2013, radial head excisions were performed for 14 elbows of 14 patients. Eleven patients were haemophilia A, whereas two patients were haemophilia B patients and the remaining one had von Willebrand (Type 3) disease. The mean age of the patients was 29 at the time of the surgery. The mean follow-up was 51 (12-155) months. VAS (visual analogue score) for pain, forearm rotation, qDASH and MEPS (Mayo Elbow Performance Score) were used as the primary outcome parameters. The mean VAS decreased significantly from 6.5 preoperatively to 2.2 at the final follow-up (p=0.0003). The mean forearm rotation increased from 40° to 115° respectively (p=0.0007). In two patients, efficacious rotation increase was not achieved due to distal radioulnar joint problems. The mean qDASH score and MEPS were 18.1 and 87.5 at the latest follow-up, respectively, where four patients had excellent and 10 patients had good results. Radial head excision is a safe and effective procedure for haemophiliac patients with radiocapitellar arthropathy and decreased forearm rotation."

According to the news reporters, the research concluded: "Distal radioulnar joint should be evaluated preoperatively which may impair the results."

Our news correspondents report that additional information may be obtained by contacting A.C. Atalar, Dept. of Orthopaedics and Traumatology, Istanbul Medical Faculty, Istanbul University, Fatih, Istanbul, Turkey. Additional authors for this research include B. Koc, F. Birisik, A. Ersen and B. Zulfikar.

**Gram-Negative Bacteria - Haemophilus influenzae**

Researchers from JMI Laboratories Discuss Findings in Haemophilus influenzae (In Vitro Activity of Delafloxacin Tested against Isolates of Streptococcus pneumoniae, Haemophilus influenzae, and Moraxella catarrhalis)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Gram-Negative Bacteria - Haemophilus influenzae. According to news reporting from North Liberty, Iowa, by NewsRx journalists, research stated, "Delafloxacin, an investigational anionic fluoroquinolone, is active against a broad range of Gram-positive and Gram-negative bacteria. In this study, 200 Streptococcus pneumoniae (plus 30 levofloxacin-resistant isolates), 200 Haemophilus
influenzae, and 100 Moraxella catarrhalis isolates selected primarily from the United States (2014) were tested against delafloxacin and comparator agents."

The news correspondents obtained a quote from the research from JMI Laboratories, "Delafloxacin was the most potent agent tested. MIC50 and MIC90 values against all S. pneumoniae isolates were 0.008 and 0.015 \( \mu \text{g/ml} \)."

According to the news reporters, the research concluded: "Delafloxacin susceptibility was not affected by beta-lactamase status against H. influenzae and M. catarrhalis."

For more information on this research see: In Vitro Activity of Delafloxacin Tested against Isolates of Streptococcus pneumoniae, Haemophilus influenzae, and Moraxella catarrhalis. Antimicrobial Agents and Chemotherapy, 2016;60(10):6381-6385. Antimicrobial Agents and Chemotherapy can be contacted at: Amer Soc Microbiology, 1752 N St NW, Washington, DC 20036-2904, USA. (American Society for Microbiology - www.asm.org; Antimicrobial Agents and Chemotherapy - aac.asm.org)

Our news journalists report that additional information may be obtained by contacting R.K. Flamm, JMI Labs, North Liberty, IA 52137, United States. Additional authors for this research include P.R. Rhomberg, M.D. Huband and D.J. Farrell.

Skin Diseases and Conditions - Psoriasis

Researchers from Jichi Medical University Discuss Findings in Psoriasis (Effects of maxacalcitol ointment on skin lesions in patients with psoriasis receiving treatment with adalimumab)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Skin Diseases and Conditions - Psoriasis. According to news reporting from Tochigi, Japan, by NewsRx journalists, research stated, "Adalimumab is a biologic that is very effective for treatment of psoriasis. However, recalcitrant or recurrent lesions sometimes occur during treatment."

The news correspondents obtained a quote from the research from Jichi Medical University, "Maxacalcitol is an active vitamin D3 ointment that is effective in treatment of psoriasis. Topical therapy may be beneficial in treatment of recalcitrant or recurrent lesions during treatment with systemic therapy, but there is little evidence on this topic. We investigated the effect of maxacalcitol on skin lesions during treatment with adalimumab in patients with psoriasis. Twelve patients with psoriasis were randomly assigned to two groups after informed consent - treatment with adalimumab only \( (n = 6) \), and treatment with adalimumab and maxacalcitol \( (n = 6) \) - and they were evaluated every 4 weeks for 44 weeks. Exacerbation was defined as an increase of the Psoriasis Area and Severity Index (PASI) score. The interval between adalimumab treatments was elongated to 3-4 weeks from 2 weeks according to the
individual patient's condition. The PASI score was evaluated every 4 weeks, and the frequency of exacerbations was counted. The overall improvement in PASI score was not statistically different between the two groups, but the frequency of exacerbations was significantly less in the maxacalcitol combination group compared with the adalimumab monotherapy group (Mann-Whitney U-test, P< 0.05). The better control of skin lesions in patients who elongated the interval of adalimumab administration was achieved in the maxacalcitol combination group compared with the adalimumab monotherapy group.”

According to the news reporters, the research concluded: "Topical maxacalcitol treatment is effective and useful in controlling skin lesions in patients with psoriasis when used in combination with adalimumab.”

Our news journalists report that additional information may be obtained by contacting M. Komine, Jichi Med Univ, Dept. of Dermatol, Shimotsuke, Tochigi 3290498, Japan. Additional authors for this research include M. Komine, M. Kishimoto, N. Maki, A. Matsumoto, J. Sugai and M. Ohtsuki.

Our reports deliver fact-based news of research and discoveries from around the world. Copyright 2017, NewsRx LLC
invasion ability of Caco-2 and SW-480 cells. Moreover, ATAD2 silencing suppressed epithelial-mesenchymal transition (EMT), and reduced the expression and enzymatic activity of matrix metalloproteinases (MMPs) in Caco-2 and SW-480 cells. In summary, our results suggest that silencing of ATAD2 inhibits migration and invasion of colorectal cancer cells by suppressing EMT and decreasing the activity of MMPs."

According to the news editors, the research concluded: "Hence, ATAD2 could be considered as a novel molecular marker of metastatic colorectal cancer, and it may provide new insights for clinical diagnosis and treatment of colorectal cancer."

For more information on this research see: Silencing of ATPase family AAA domain-containing protein 2 inhibits migration and invasion of colorectal cancer cells. *Neoplasma*, 2016;63(6):846-855. *Neoplasma* can be contacted at: Aepress Sro, Bajzova 7, Bratislava, 821 08, Slovakia.

**Oncology - Non-Small Cell Lung Cancer**

**Researchers from Jilin University Report Recent Findings in Non-Small Cell Lung Cancer (Upregulation of LncRNA-HIT promotes migration and invasion of non-small cell lung cancer cells by association with ZEB1)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Oncology - Non-Small Cell Lung Cancer is now available. According to news reporting originating from Changchun, People's Republic of China, by NewsRx correspondents, research stated, "Lung cancer is the most common solid tumor and the leading cause of cancer-related mortality worldwide. Non-small cell lung cancer (NSCLC) accounts for approximately 80% of all lung cancer cases."

Our news editors obtained a quote from the research from Jilin University, "The main reason of lung cancer-related deaths is due to tumor metastasis. But, the mechanisms of NSCLC metastasis remains poorly understood. LncRNAs play pivotal roles in multiple biological processes. LncRNA-HIT (HOXA transcript induced by TGF beta) was recently identified. LncRNA-HIT promotes cell migration, invasion, tumor growth, and metastasis. However, the detailed role of lncRNA-HIT in NSCLC remains unknown. In this study, for the first time, we revealed a novel role of lncRNA-HIT in the migration and invasion of NSCLC cells. The expression of lncRNA-HIT was significantly upregulated in NSCLC tissues and cell lines, and the expression level of lncRNA-HIT correlates with advanced disease stage and predicts unfavorable prognosis of NSCLC patients. Functional assays demonstrated that..."
IncRNA-HIT markedly increased the ability of NSCLC cells to migrate and invade. Furthermore, the molecular mechanism by which IncRNA-HIT affects NSCLC cells was associated with regulation of ZEB1 stability. IncRNA-HIT functions as a prometastasis oncogene by directly associating with ZEB1 to regulate NSCLC.

According to the news editors, the research concluded: "The interaction of IncRNA-HIT and ZEB1 may be a potential target for NSCLC therapy."

The news editors report that additional information may be obtained by contacting L. Yu, Jilin University, Dept. of Radiotherapy, Hosp 2, Changchun 130041, People's Republic of China. Additional authors for this research include Z.C. Wang, L. Qiu, Y.M. Yang, Y.L. Wang, Z.S. Chen, Z.S. Liu and L. Yu.

Oncology - Prostate Cancer

Researchers from Jilin University Report on Findings in Prostate Cancer (Flavonoids intake and risk of prostate cancer: a meta-analysis of observational studies)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Oncology - Prostate Cancer is the subject of a report. According to news reporting originating from Changchun, People's Republic of China, by NewsRx correspondents, research stated, "The aim of the study was to assess the association between total flavonoids/flavonoid subclasses intake and prostate cancer risk. Several databases were searched to select eligible studies with predefined criteria."

Financial support for this research came from Scientific Research Programs Of Jilin Provincial Health Department.

Our news editors obtained a quote from the research from Jilin University, "Risk ratios (RRs) with 95% confidence intervals (CIs) were used as the effect size. Publication bias and sensitivity analysis were performed. A total of five studies including four prospective cohort studies and one case-control study were included in the meta-analysis. The pooled result demonstrated a significantly increased risk of prostate cancer with higher intake of total flavonoids (RR = 1.12, 95% CI: 1.02-1.23, P = 0.013). However, sensitivity analysis indicated that there lacked a significant association after removing the study of Wang et al. (RR = 1.17, 95% CI: 0.94-1.46). Subgroup analysis stratified by flavonoids subclasses found that higher intake of anthocyanidins and flavan-3-ols were significantly associated with increased prostate cancer risk (RR = 1.12, 95% CI: 1.03-1.21, P = 0.011; RR = 1.21, 95% CI: 1.10-1.32, P<
0.001). Sensitivity analysis also indicated that after removing Wang's study, no significant association between anthocyanidins intake and prostate cancer risk was detected (RR = 1.22, 95% CI: 0.97-1.54)."

According to the news editors, the research concluded: "Higher intake of flavonoids may not be associated with prostate cancer risk."

The news editors report that additional information may be obtained by contacting H. Wang, Jilin University, Hosp 1, Dept. of Androl, Changchun 130021, People's Republic of China. Additional authors for this research include Z. Liang, L. Liu, F. Li and H. Wang.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1111/and.12556. This DOI is a link to an online electronic document that is either free or for purchase.

Gram-Negative Bacteria - Acinetobacter

Researchers from Johann Wolfgang Goethe-University Report Details of New Studies and Findings in the Area of Acinetobacter (Osmotic stress response in Acinetobacter baylyi: identification of a glycine-betaine biosynthesis pathway and regulation ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Gram-Negative Bacteria - Acinetobacter. According to news reporting out of Frankfurt, Germany, by NewsRx editors, research stated, "Acinetobacter baylyi, a ubiquitous soil bacterium, can cope with high salinity by uptake of choline as precursor of the compatible solute glycine betaine. Here, we report on the identification of a choline dehydrogenase (BetA) and a glycine betaine aldehyde dehydrogenase (BetB) mediating the oxidation of choline to glycine betaine."

Financial supporters for this research include Deutsche Forschungsgemeinschaft, Stiftung Polytechnische Gesellschaft.

Our news journalists obtained a quote from the research from Johann Wolfgang Goethe-University, "The betAB genes were found to form an operon together with the potential transcriptional regulator betI. The transcription of the betIBA operon and the two recently identified choline transporters was upregulated in response to choline and choline plus salt. The finding that the osmo-independent transporter BetT1 undergoes a higher upregulation in response to choline alone than betT2 suggests that BetT1 does not primarily function in osmoadaptation. Electrophoretic mobility shift assays led to the conclusion that BetI mediates transcriptional regulation of both, the betIBA gene operon and the choline transporters."
According to the news editors, the research concluded: "BetI was released from the DNA in response to choline which together with the transcriptional upregulation of the bet genes in the presence of choline suggests that BetI is a choline sensing transcriptional repressor."

Our news journalists report that additional information may be obtained by contacting A. Scholz, Dept. of Molecular Microbiology & Bioenergetics, Institute of Molecular Biosciences, Johann Wolfgang Goethe University Frankfurt, Frankfurt am Main, Germany. Additional authors for this research include J. Stahl, V. de Berardinis, V. Muller and B. Averhoff.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1111/1758-2229.12382. This DOI is a link to an online electronic document that is either free or for purchase.

Oncology - Gastric Cancer

Researchers from Johns Hopkins University Hospital Discuss Findings in Gastric Cancer (Patterns of PD-L1 expression and CD8 T cell infiltration in gastric adenocarcinomas and associated immune stroma)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Oncology - Gastric Cancer. According to news reporting originating from Baltimore, Maryland, by NewsRx correspondents, research stated, "Recent data supports a significant role for immune checkpoint inhibitors in the treatment of solid tumours. Here, we evaluate gastric and gastro-oesophageal junction (G/GEJ) adenocarcinomas for their expression of programmed death-ligand 1 (PD-L1), infiltration by CD8+ T cells and the relationship of both factors to patient survival."

Our news editors obtained a quote from the research from Johns Hopkins University Hospital, "Thirty-four resections of primary invasive G/GEJ were stained by immunohistochemistry for PD-L1 and CD8 and by DNA in situ hybridisation for Epstein-Barr virus (EBV). CD8+ T cell densities both within tumours and at the tumour-stromal interface were analysed using whole slide digital imaging. Patient survival was evaluated according to PD-L1 status and CD8 density. 12% of resections showed tumor cell membranous PD-L1 expression and 44% showed expression within the immune stroma. Two cases (6%) were EBV positive, with one showing membranous PD-L1 positivity. Increasing CD8+ densities both
within tumours and immune stroma was associated with increasing percentage of tumor (p=0.027) and stromal (p=0.005) PD-L1 expression. Both tumor and immune stromal PD-L1 expression and high intratumoral or stromal CD8+ T cell density (>500/mm) were associated with worse progression-free survival (PFS) and overall survival (OS). PD-L1 is expressed on both tumor cells and in the immune stroma across all stages and histologies of G/GEJ. Surprisingly, we demonstrate that increasing CD8 infiltration is correlated with impaired PFS and OS. Patients with higher CD8+ T cell densities also have higher PD-L1 expression, indicating an adaptive immune resistance mechanism may be occurring."

According to the news editors, the research concluded: "Further characterisation of the G/GEJ immune microenvironment may highlight targets for immune-based therapy."

For more information on this research see: Patterns of PD-L1 expression and CD8 T cell infiltration in gastric adenocarcinomas and associated immune stroma. *Gut*, 2016;(). (BMJ Publishing Group - group.bmj.com; Gut - gut.bmj.com/)

**Immune System Diseases and Conditions - HIV/AIDS**

**Researchers from Johns Hopkins University Report Findings in HIV/AIDS (A Medical Care Missed Opportunity: Preexposure Prophylaxis and Young Black Men Who Have Sex With Men)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Immune System Diseases and Conditions - HIV/AIDS have been published. According to news originating from Baltimore, Maryland, by NewsRx correspondents, research stated, "HIV disproportionately impacts young black men who have sex with men (YBMSM). Preexposure prophylaxis (PrEP) is an effective strategy that can avert new HIV infections in YBMSM."

Our news journalists obtained a quote from the research from Johns Hopkins University, "Barriers exist for YBMSM to access PrEP. We sought to determine factors associated with awareness of and willingness to take PrEP in a sample of YBMSM. Only 8% were currently on PrEP despite many (66%) reporting condomless anal sex, a recent provider visit (54%), disclosing their sexual orientation to their regular medical provider (62%), or a willingness to take PrEP (62%). In bivariate analysis, increased number of lifetime partners, current PrEP use, and disclosure of sexual orientation to a doctor were associated with awareness of PrEP, while condomless anal sex and higher perceived risk was associated with willingness to take PrEP. Sex with females was associated with lower willingness."

According to the news editors, the research concluded: "Providers may be missing
key opportunities to educate YBMSM about PrEP and incorporate PrEP into comprehensive sexual health care."

The news correspondents report that additional information may be obtained from R. Arrington-Sanders, Johns Hopkins University, Sch Med, Dept. of Pediat, Div Gen Pediat & Adolescent Med, Baltimore, MD 21205, United States. Additional authors for this research include A. Morgan, J. Oidtman, I. Qian, D. Celentano and C. Beyrer.

Nanotechnology - Nanoparticles

Researchers from Johns Hopkins University Report on Findings in Nanoparticles (Polysaccharide-based nanoparticles for theranostic nanomedicine)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Nanotechnology - Nanoparticles. According to news reporting originating in Baltimore, Maryland, by NewsRx journalists, research stated, "Polysaccharides are natural biological molecules that have numerous advantages for theranostics, the integrated approach of therapeutics and diagnostics. Their derivable reactive groups can be leveraged for functionalization with a nanoparticle-enabling conjugate, therapeutics (small molecules, proteins, peptides, photosensitizers) and/or diagnostic agents (imaging agents, sensors)."

Funders for this research include US National Institutes of Health, US Department of Defense, NRF.

The news reporters obtained a quote from the research from Johns Hopkins University, "In addition, polysaccharides are diverse in size and charge, biodegradable and abundant and show low toxicity in vivo. Polysaccharide-based nanoparticles are increasingly being used as platforms for simultaneous drug delivery and imaging and are therefore becoming popular theranostic nanoparticles. The review focuses on the method of nanoparticle formation (self-assembled, physical or chemical cross-linked) when engineering polysaccharide-based nanoparticles for theranostic nanomedicine."

According to the news reporters, the research concluded: "We highlight recent examples of polysaccharide-based theranostic systems from literature and their potential for use
in the clinic, particularly chitosan-and hyaluronic acid-based NPs."

Our news correspondents report that additional information may be obtained by contacting M. Swierczewska, Russell H Morgan Dept. of Radiology and Radiological Science, Center for Cancer Nanotechnology Excellence, Center for Nanomedicine at the Wilmer Eye Institute, Johns Hopkins University, 400 North Broadway, Baltimore, MD 21231, United States. Additional authors for this research include H.S. Han, K. Kim, J.H. Park and S. Lee.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1016/j.addr.2015.11.015. This DOI is a link to an online electronic document that is either free or for purchase.

**Genetics - Medical Genetics**

**Researchers from Jonkoping University Describe Findings in Medical Genetics (Abnormal primary and permanent dentitions with ectodermal symptoms predict WNT10A deficiency)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Genetics - Medical Genetics have been published. According to news reporting out of Jonkoping, Sweden, by NewsRx editors, research stated, "The WNT10A protein is critical for the development of ectodermal appendages. Variants in the WNT10A gene may be associated with a spectrum of ectodermal abnormalities including extensive tooth agenesis."

Our news journalists obtained a quote from the research from Jonkoping University, "In seven patients with severe tooth agenesis we identified anomalies in primary dentition and additional ectodermal symptoms, and assessed WNT10A mutations by genetic analysis. Investigation of primary dentition revealed peg-shaped crowns of primary mandibular incisors and three individuals had agenesis of at least two primary teeth. The permanent dentition was severely affected in all individuals with a mean of 21 missing teeth. Primary teeth were most often present in positions were succedaneous teeth were missing. Furthermore, most existing molars had taurodontism. Light, brittle or coarse hair was reported in all seven individuals, hyperhidrosis of palms and soles in six individuals and nail anomalies in two individuals. The anomalies in primary dentition preceded most of the additional ectodermal symptoms. Genetic analysis revealed that all seven individuals were homozygous or compound heterozygous for WNT10A mutations resulting in C107X, E222X and F228I."

According to the news editors, the research concluded: "We conclude that tooth agenesis and/or peg-shaped crowns of primary mandibular incisors, severe oligodontia of permanent dentition as well as ectodermal symptoms of varying severity may be predictors of biallelic WNT10A mutations of importance for diagnosis, counselling and follow-up."
For more information on this research see: Abnormal primary and permanent dentitions with ectodermal symptoms predict WNT10A deficiency. *BMC Medical Genetics*, 2016;17():1-7. *BMC Medical Genetics* can be contacted at: Biomed Central Ltd, 236 Grays Inn Rd, Floor 6, London WC1X 8HL, England. **Drugs and Therapies - Coumarins and Indandiones**

**Researchers from Juntendo University Report Recent Findings in Coumarins and Indandiones (Adequate time in therapeutic INR range using triple antithrombotic therapy is not associated with long-term cardiovascular events and major bleeding ...)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Drugs and Therapies - Coumarins and Indandiones have been presented. According to news reporting originating in Tokyo, Japan, by NewsRx journalists, research stated, "Triple antithrombotic therapy increases the risk of bleeding events in patients undergoing percutaneous coronary intervention (PCI) compared with dual anti-platelet therapy (DAPT). However, whether warfarin control is associated with reduced cardiovascular events and major bleeding events in patients undergoing PCI with triple antithrombotic therapy is uncertain."

Financial support for this research came from Ministry of Health, Labor and Welfare.

The news reporters obtained a quote from the research from Juntendo University, "We investigated 1207 consecutive patients who underwent PCI between 2004 and 2011. Major bleeding complications and major adverse cardiac and cerebrovascular events (MACCE) defined as all cause death, acute coronary syndrome, target vessel revascularization, and stroke were compared between groups of patients who received either triple antithrombotic therapy or DAPT. Triple antithrombotic therapy was administered to 95 (7.9%) patients. The mean international normalized ratio of prothrombin time (PT-INR) was 1.8. The target PT-INR level was set between 1.6 and 2.6 and the ratio (%) of time in the therapeutic range (TTR) was calculated. The median TTR was 78.4% (interquartile range, 67.4-87.6%). Kaplan-Meier survival curves showed that warfarin therapy was not associated with MACCE (p = 0.89) and major bleeding (p = 0.80). Multivariable Cox regression analysis revealed that triple antithrombotic therapy was not an independent predictor of MACCE and major bleeding."

According to the news reporters, the research concluded: "Triple antithrombotic therapy does not increase the occurrence of MACCE and major bleeding complications, if the warfarin dose is tightly controlled with a lower INR."

For more information on this research see: Adequate time in therapeutic INR range using triple antithrombotic therapy is not associated with long-term cardiovascular events and major bleeding complications after drug-eluting stent implantation. *Journal of Cardiology*,
Researchers from KIIT University Describe Findings in Antibodies (The Hha-TomB Toxin-Antitoxin System Shows Conditional Toxicity and Promotes Persister Cell Formation by Inhibiting Apoptosis-Like Death in S. Typhimurium)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Immunology - Antibodies have been published. According to news reporting originating in Bhubaneswar, India, by NewsRx journalists, research stated, "Toxin-antitoxin (TA) modules are two component 'addictive' genetic elements found on either plasmid or bacterial chromosome, sometimes on both. TA systems perform a wide range of functions like biofilm formation, persistence, programmed cell death, phage abortive infection etc."

The news reporters obtained a quote from the research from KIIT University, "Salmonella has been reported to contain several such TA systems. However, the hemolysin expression modulating protein (Hha) and its adjacent uncharacterized hypothetical protein TomB (previously known as YbaJ), have not been listed as a TA module in Salmonella. In this study we established that Hha and TomB form a bonafide TA system where Hha serves as a toxin while TomB functions as an antitoxin. Interestingly, the toxicity of Hha was conditional causing cell death under acid stress. The antitoxin attenuated the toxicity of Hha by forming a TA complex through stable interactions. The Hha-TomB TA system was found to increase persistence and inhibit programmed cell death under antibiotic stress where a phenotypically diverse population expressing differential level of TA components was observed."

According to the news reporters, the research concluded: "Therefore we propose that Hha and TomB prevent cells from committing suicide thereby promoting persister cell formation."

For more information on this research see: The Hha-TomB Toxin-Antitoxin System Shows Conditional Toxicity and Promotes Persister Cell Formation by Inhibiting Apoptosis-

**Heart Disorders and Diseases - Heart Failure**

**Researchers from Kameda Medical Center Detail Findings in Heart Failure (Renal function on admission modifies prognostic impact of diuretics in acute heart failure: a propensity score matched and interaction analysis)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Heart Disorders and Diseases - Heart Failure is the subject of a report. According to news reporting originating in Chiba, Japan, by NewsRx journalists, research stated, "Although intravenous diuretics have been mainstay drugs in patients with acute heart failure (AHF), they have been suggested to have some deleterious effects on prognosis. We postulated that renal function may modify their deleterious effects in AHF patients."

The news reporters obtained a quote from the research from Kameda Medical Center, "The study population consisted of 1094 AHF patients from three hospitals. Renal dysfunction (RD) was defined as estimated glomerular filtration rate (eGFR) < 60 mL/min/1.73 m(2) on admission, and the cohort was divided into a high-dose furosemide (ae <yen >100 mg/48 h) and low-dose furosemide group according to the amount of intravenous furosemide used within 48 h from admission. In the whole cohort, in-hospital mortality rate was higher in the high-dose furosemide group than the low-dose furosemide group (12.5 vs. 6.6 %, respectively, P = 0.001). However, this difference in the in-hospital mortality rates was significant only in the RD subgroup (15.6 vs. 7.0 %, respectively, P< 0.001), and not in the non-RD subgroup (2.5 vs. 5.9 %, respectively, P = 0.384). Propensity score-matched analysis was performed to evaluate the impact of high-dose furosemide on prognosis. After propensity score matching, high-dose furosemide was not associated with in-hospital mortality (OR 1.25, 95 % CI 0.73-2.16, P = 0.408). However, there was a qualitative difference in OR for in-hospital mortality between AHF with RD (OR 1.77, 95 % CI 0.96-3.28, P = 0.068) and without RD (OR 0.23, 95 % CI 0.05-1.10, P = 0.064), and there was a significant interaction between eGFR and prognostic impact of high-dose furosemide (P for OR interaction = 0.013). An inverse relationship was observed between eGFR and OR for in-hospital death in the group treated with high-dose furosemide (decreasing OR with better eGFR). The deleterious effect of diuretics was
significantly modified with renal function in AHF."

According to the news reporters, the research concluded: "This association may be one reason for poorer prognosis of AHF patients complicated with renal impairment."

For more information on this research see: Renal function on admission modifies prognostic impact of diuretics in acute heart failure: a propensity score matched and interaction analysis. Oncology - Liver Cancer

Researchers from Kanazawa Medical University Report Details of New Studies and Findings in the Area of Liver Cancer (Association between transforming growth factor-beta 1-509 C > T variants and hepatocellular carcinoma susceptibility: a ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Oncology - Liver Cancer are presented in a new report. According to news reporting out of Ishikawa, Japan, by NewsRx editors, research stated, "The transcriptional activity of transforming growth factor-beta (TGF-beta) is increased in subjects with hepatocellular carcinoma (HCC). Recent studies have indicated that the -509C genotype in hepatitis B virus (HBV)-infected subjects and the -509T genotype in hepatitis C virus (HCV)-infected subjects can increase the transcriptional activity of the TGF-beta 1 gene."

Our news journalists obtained a quote from the research from Kanazawa Medical University, "We conducted a meta-analysis to clarify whether these two hepatitis viruses affect the association between TGF-beta 1 C-509T variants and HCC susceptibility. Using data derived from 8 case-control studies available in the PubMed database (5 with Asian and 3 with Caucasian populations), including 1,427 cases and 3,735 controls [1,610 patients with chronic liver disease and 2,125 healthy controls], we calculated pooled odds ratios with corresponding 95% confidence intervals. We used dominant (TT + CT vs. CC), recessive (TT vs. CC + CT), and co-dominant (TT vs. CC and CT vs. CC) genetic models. An overall analysis showed no association between the TGF-beta 1 C-509T variants and HCC susceptibility for all models. In
contrast, a subgroup analysis, based on the infecting hepatitis viruses, provided the following results. Among the cases and controls with chronic liver disease, the TGF-beta 1 C-509T variants were significantly associated with decreased HCC susceptibility for two models with HBV-infected subjects, whereas the variants were significantly associated with increased HCC susceptibility for one model with HCV-infected subjects. Among the cases and healthy controls, there was a significant association between the TGF-beta 1 C-509T variants and increased HCC susceptibility for two models involving HCV-infected subjects. Among the cases and the entire control group, the same results were obtained for all genetic models with HCV-infected subjects.

According to the news editors, the research concluded: "Although further data accumulation is required, our results suggest that these two hepatitis viruses affect the association between TGF-beta 1 C-509T variants and HCC susceptibility in opposite manners."

Our news journalists report that additional information may be obtained by contacting N. Toshikuni, Kanazawa Medical University, Dept. of Hepatol, Uchinada, Ishikawa, Japan. Additional authors for this research include Y. Matsue, T. Minato, N. Hayashi and M. Tsutsumi.

Researchers from Kanazawa University Report Details of New Studies and Findings in the Area of Thrombocytopenia [Hypomegakaryocytic thrombocytopenia (HMT): an immune-mediated bone marrow failure characterized by an increased number of ...]

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Hematologic Diseases and Conditions - Thrombocytopenia is the subject of a report. According to news reporting from Ishikawa, Japan, by NewsRx journalists, research stated, "Patients with mild hypomegakaryocytic thrombocytopenia (HMT) that does not meet the diagnostic criteria for a definite disease entity may potentially progress to aplastic anaemia (AA) that is refractory to therapy. To clarify the clinical picture of HMT, we prospectively followed 25 HMT patients with white blood cell count >30x10(9)/l, haemoglobin level >100g/l and platelet count of <1000x10(9)/l in the absence of morphological and karyotypic abnormalities in the bone marrow."
The news correspondents obtained a quote from the research from Kanazawa University. "Glycosylphosphatidylinositol-anchored protein-deficient blood cells [paroxysmal nocturnal haemoglobinuria (PNH)-type cells] were detected in 7 of the 25 (28%) patients and elevated plasma thrombopoietin (TPO, also termed THPO) levels (>320pg/ml) were observed in 11 (44%) patients. Five (four PNH+ and one PNH-) of six TPOhigh patients who were treated with ciclosporin (CsA) showed improvement. Among the 21 patients who were followed without treatment, thrombocytopenia progressed in four of ten TPOlow patients and four of 11 TPOhigh patients. The 3-year failure-free survival rate of the CsA-treated TPOhigh patients (100%) was significantly higher than that of the untreated TPOhigh patients (20%)."

According to the news reporters, the research concluded: "These results suggest that a significant population of HMT patients has an immune pathophysiology that is similar to AA and may be improved by early therapeutic intervention with CsA."

Our news journalists report that additional information may be obtained by contacting S. Nakao, Kanazawa University, Cellular Transplantat Biol, Grad Sch Med Sci, Kanazawa, Ishikawa, Japan. Additional authors for this research include K. Ishiyama, H. Yamazaki, Y. Zaimoku and S. Nakao.

Cardiovascular Diseases and Conditions -…

Researchers from Kansai Medical University Report Findings in Hypertension (A Practical Training Program for Peripheral Radial Artery Catheterization in Adult Patients A Prospective, Randomized Controlled Trial)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Cardiovascular Diseases and Conditions - Hypertension is the subject of a report. According to news reporting originating in Osaka, Japan, by NewsRx journalists, research stated, "The main cause of unsuccessful peripheral radial artery catheterization using traditional palpation is imprecisely locating the arterial center. The authors evaluated factors causing disparities between the arterial centers determined by palpation versus ultrasound."
The news reporters obtained a quote from the research from Kansai Medical University. "The authors applied them to create and test a novel catheterization training program. The arterial central axis was determined by ultrasound and palpation in 350 adults. Potential independent predictors of disparity included sex, body mass index, pulse pressure, transverse arterial diameter, subcutaneous arterial depth, chronic hypertension, and experience as an anesthesiologist (less than 3 vs. greater than or equal to 3 yr). Using the results, the authors developed a radial artery catheterization training program. It was tested by enrolling 20 first-year interns, randomized to a training or control group. The time to successful insertion was the primary outcome measure. The success rate and time required for catheterization by palpation were evaluated in 100 adult patients per group. Independent predictors of central axis disparity were pulse pressure, subcutaneous radial artery depth, years of experience, and chronic hypertension. Training improved the catheterization time (training group 56 +/- 2 s vs. control group 109 +/- 2 s; difference -53 +/- 3 s; 95% CI, -70 to -36 s; P< 0.0001) and total success rate (training group 83 of 100 attempts, 83%; 95% CI, 75 to 90 vs. control group 57 of 100, 57%; 95% CI, 47 to 66; odds ratio, 3.7; 95% CI, 2.7 to 5.1). Misjudging the central axis position of the radial artery is common with a weak pulse and/or deep artery."

According to the news reporters, the research concluded: "The authors' program, which focused on both these issues, shortened the time for palpation-guided catheterization and improved success."

For more information on this research see: A Practical Training Program for Peripheral Radial Artery Catheterization in Adult Patients A Prospective, Randomized Controlled Trial. Anesthesiology, 2016;125(4):716-723. Anesthesiology can be contacted at: Lippincott Williams & Wilkins, Two Commerce Sq, 2001 Market St, Philadelphia, PA 19103, USA. Liver Diseases and Conditions - Hepatitis C Virus

Researchers from Kaohsiung Medical University Hospital Report Recent Findings in Hepatitis C Virus (Long-term efficacy of Peg-Interferon/Ribavirin with and without Lamivudine therapy for HBeAg-positive hepatitis B and C dual infection)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Liver Diseases and Conditions - Hepatitis C Virus are presented in a new report. According to news reporting originating in Kaohsiung, Taiwan, by NewsRx journalists, research stated, "The optimal therapeutic strategy for hepatitis B virus (HBV) e antigen (HBeAg)-seropositive and hepatitis C virus (HCV) dually infected patients
remains unknown. We aimed to elucidate the effectiveness of peginterferon (Peg-IFN)/ribavirin (RBV) with and without lamivudine (LAM) combination therapy in the clinical settings."

The news reporters obtained a quote from the research from Kaohsiung Medical University Hospital, "Nine patients seropositive for HBV surface antigen, HBeAg, antibodies to HCV and HCV RNA for >6 months were treated with Peg-IFN/RBV with (n=5) and without (n=4) a 12-month LAM add-on therapy at treatment week 12. The treatment duration of Peg-IFN/RBV was 24 weeks (HCV genotype 1 [HCV-1] with rapid virological response [RVR] or HCV-2) or 48 weeks (HCV-1 without RVR). Primary endpoints included HBeAg loss and HCV-sustained virological response (SVR). All of the nine patients had undetectable HCV RNA at treatment weeks 4 and 12 and end-of-Peg-IFN/RBV therapy. However, SVR was achieved in 100% of patients treated with triple therapy, compared with only 50% in those with Peg-IFN/RBV therapy (p=0.167). The 3-year durability of HCV SVR was 100%. HBeAg loss and HBV DNA <2000 IU/mL at 6 months post-LAM treatment were found in 100% and 40% of patients treated with triple therapy, compared with none of the four patients with Peg-IFN/RBV therapy achieved any HBV responses. Of the five patients with triple therapy, four had persistent HBeAg loss during 3-year follow-up period; one developed HBeAg seroreversion 15 months after treatment. For HBeAg-positive HBV/HCV dually infected patients, Peg-IFN/RBV was effective for HCV eradication."

According to the news reporters, the research concluded: "Add-on LAM might promote HBeAg loss in the clinical setting."

Our news correspondents report that additional information may be obtained by contacting M.L. Yeh, Hepatobiliary Division, Dept. of Internal Medicine and Hepatitis Center, Kaohsiung Medical University Hospital, Kaohsiung, Taiwan. Additional authors for this research include M.Y. Hsieh, C.I. Huang, C.F. Huang, M.H. Hsieh, J.F. Huang, C.Y. Dai, W.L. Chuang and M.L Yu.

Ethanol

Researchers from Karnatak University Report Recent Findings in Ethanol (Evaluation of wound healing property of Caesalpinia mimosoides Lam)
2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Ethanol have been presented. According to news reporting originating in Karnataka, India, by NewsRx journalists, research stated, "Ethnopharmacological relevance: Caesalpinia mimosoides Lam. is one of the important traditional folk medicinal plants in the treatment of skin diseases and wounds used by healers of Uttara Kannada district of Karnataka state (India). However scientific validation of documented traditional knowledge related to medicinal plants is an important path in current scenario to fulfill the increasing demand of herbal medicine."

Funders for this research include UGC, UPE, RFSMS.

The news reporters obtained a quote from the research from Karnatak University, "Aim of the study: The study was carried out to evaluate the claimed uses of Caesalpinia mimosoides using antimicrobial, wound healing and antioxidant activities followed by detection of possible active bio-constituents. Extracts prepared by hot percolation method were subjected to preliminary phytochemical analysis followed by antimicrobial activity using MIC assay. In vivo wound healing activity was evaluated by circular excision and linear incision wound models. The extract with significant antimicrobial and wound healing activity was investigated for antioxidant capacity using DPPH, nitric oxide, antilipid peroxidation and total antioxidant activity methods. Total phenolic and flavonoid contents were also determined by Folin-Ciocalteu, Swain and Hillis methods. Possible bio-active constituents were identified by GC-MS technique. RP-UFLC-DAD analysis was carried out to quantify ethyl gallate and gallic acid in the plant extract. Preliminary phytochemical analysis showed positive results for ethanol and aqueous extracts for all the chemical constituents. The ethanol extract proved potent antimicrobial activity against both bacterial and fungal skin pathogens compared to other extracts. The efficacy of topical application of potent ethanol extract and traditionally used aqueous extracts was evidenced by the complete re-epithelization of the epidermal layer with increased percentage of wound contraction in a shorter period. However, aqueous extract failed to perform a consistent effect in the histopathological assessment. Ethanol extract showed effective scavenging activity against DPPH and nitric oxide free radicals with an expressive amount of phenolic and moderate concentration of flavonoid contents. Ethyl gallate and gallic acid were found to be the probable bio-active compounds evidenced by GCMS and RP-UFLC-DAD analysis."

According to the news reporters, the research concluded: "The study revealed the significant antimicrobial, wound healing and antioxidant activities of tender parts of C. mimosoides and proved the traditional folklore knowledge."

Our news correspondents report that additional information may be obtained by contacting P.B. Bhat, Karnatak Univ, PG Dept. of Studies Bot, Dharwad 580003, Karnataka, India. Additional authors for this research include S. Hegde, V. Upadhya, G.R. Hegde, P.V. Habbu and G.S. Mulgund.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1016/j.jep.2016.10.009. This DOI is a link to an online electronic document that is either free or for purchase.

Researchers from Karolinska Institute Detail New Studies and Findings in the Area of Human Genetics (One CNV Discordance in NRXN1 Observed Upon Genome-wide Screening in 38 Pairs of Adult Healthy Monozygotic Twins)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Genetics - Human Genetics. According to news reporting originating from Stockholm, Sweden, by NewsRx correspondents, research stated, "Monozygotic (MZ) twins stem from the same single fertilized egg and therefore share all their inherited genetic variation. This is one of the unequivocal facts on which genetic epidemiology and twin studies are based."

Our news editors obtained a quote from the research from Karolinska Institute, "To what extent this also implies that MZ twins share genotypes in adult tissues is not precisely established, but a common pragmatic assumption is that MZ twins are 100% genetically identical also in adult tissues. During the past decade, this view has been challenged by several reports, with observations of differences in post-zygotic copy number variations (CNVs) between members of the same MZ pair. In this study, we performed a systematic search for differences of CNVs within 38 adult MZ pairs who had been misclassified as dizygotic (DZ) twins by questionnaire-based assessment. Initial scoring by PennCNV suggested a total of 967 CNV discordances. The within-pair correlation in number of CNVs detected was strongly dependent on confidence score filtering and reached a plateau of r=0.8 when restricting to CNVs detected with confidence score larger than 50. The top-ranked discordances were subsequently selected for validation by quantitative polymerase chain reaction (qPCR), from which one single ~120kb deletion in NRXN1 on chromosome 2 (bp 51017111-51136802) was validated."

According to the news editors, the research concluded: "Despite involving an exon, no sign of cognitive/mental consequences was apparent in the affected twin pair, potentially reflecting limited or lack of expression of the transcripts containing this exon in nerve/brain."

For more information on this research see: One CNV Discordance in NRXN1 Observed Upon Genome-wide Screening in 38 Pairs of Adult Healthy Monozygotic Twins. Twin Research and Human Genetics, 2016;19(2):97-103. (Cambridge University Press - www.cambridge.org; Twin Research and Human Genetics - journals.cambridge.org/action/displayJournal?jid=THG)

The news editors report that additional information may be obtained by contacting P.K. Magnusson, Dept. of Medical Epidemiology and Biostatistics, Karolinska Institutet, Stockholm, Sweden. Researchers from Karolinska Institute Detail New Studies and Findings in the Area of Toxicology and Pharmacology (Surface passivity largely governs the bioaccessibility of nickel-based powder particles at human exposure conditions)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Drugs and Therapies - Toxicology and Pharmacology are presented in a new report. According to news reporting from Stockholm, Sweden, by NewsRx journalists, research stated, "The European chemical framework REACH requires that hazards and risks posed by chemicals, including alloys and metals, are identified and proven safe for humans and the environment. Therefore, differences in bioaccessibility in terms of released metals in synthetic biological fluids (different pH (1.5-7.4) and composition) that are relevant for different human exposure routes (inhalation, ingestion, and dermal contact) have been assessed for powder particles of an alloy containing high levels of nickel (Inconel 718, 57 wt% nickel)."

The news correspondents obtained a quote from the research from Karolinska Institute, "This powder is compared with the bioaccessibility of two nickel-containing stainless steel powders (AISI 316L, 10-12% nickel) and with powders representing their main pure alloy constituents: two nickel metal powders (100% nickel), two iron metal powders and two chromium metal powders. Xray photoelectron spectroscopy, microscopy, light scattering, and nitrogen absorption were employed for the particle and surface oxide characterization. Atomic absorption spectroscopy was used to quantify released amounts of metals in solution. Cytotoxicity (Alamar blue assay) and DNA damage (comet assay) of the Inconel powder were assessed following exposure of the human lung cell line A549, as well as its ability to generate reactive oxygen species (DCFH-DA assay). Despite its high nickel content, the Inconel alloy powder did not release any significant amounts of metals and did not induce any toxic response. It is concluded, that this is related to the high surface passivity of the Inconel powder governed by its chromium-rich surface oxide."

According to the news reporters, the research concluded: "Read-across from the pure metal constituents is hence not recommended either for this or any other passive alloy."

For more information on this research see: Surface passivity largely governs the bioaccessibility of nickel-based powder particles at human exposure conditions. Regulatory Toxicology and Pharmacology, 2016;81():162-170. Regulatory Toxicology and Pharmacology can be contacted at: Academic Press Inc Elsevier Science, 525 B St, Ste 1900, San Diego, CA 92101-4495, USA. Researchers from Karolinska Institute Report on Findings in Inflammation Mediators (Dysfunctions in the migratory phenotype and properties of circulating immature transitional B cells during HIV-1 infection)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Biological Factors - Inflammation Mediators have been published. According to news reporting originating from Stockholm, Sweden, by NewsRx correspondents, research stated, "The frequency of immature transitional B cells is increased in blood of HIV-1-infected individuals. We investigated whether HIV-1 infection affects expression and function of chemokine receptors important for egress of immature transitional B cells from bone marrow and migration to lymphoid organs."

Our news editors obtained a quote from the research from Karolinska Institute, "This is a cross-sectional study analysing the migratory phenotype and function of immature transitional B cells in HIV-1-infected individuals, in relation to anti-retroviral treatment and age. Frequency of blood immature transitional B cells and their phenotypic characteristics, including chemokine receptors and a maturation marker, were determined by immunostainings. Migratory capacities were studied in a migration assay. The increased frequency of immature transitional B cells in untreated HIV-1 infection was normalized in patients receiving antiretroviral treatment; in our cohorts, age did not have an impact on the frequency of circulating immature transitional B cells. Immature transitional B cells from nontreated patients expressed low levels of CD21 molecule. We found an elevated frequency of CXCR3 and CXCR4 expressing immature transitional B cells in treated and nontreated patients. CXCR4 receptor was unresponsive to CXCL12 ligand in in-vitro migration and internalization assays. In addition, CXCR5 expression was downregulated on immature transitional B cells from infected patients, and these cells migrated poorly in response to CXCR5 ligand. Circulating immature transitional B cells from HIV-1-infected patients are not fully mature, probably due to premature egress from bone marrow; these cells showed a phenotype which could impair entry into secondary lymphoid organs."

According to the news editors, the research concluded: "Changes in migratory capacity of immature transitional B cells may affect B-cell maturation during HIV-1 infection."

For more information on this research see: Dysfunctions in the migratory phenotype and properties of circulating immature transitional B cells during HIV-1 infection. Aids, 2016;30(14):2169-2177. Aids can be contacted at: Lippincott Williams & Wilkins, Two Commerce Sq, 2001 Market St, Philadelphia, PA 19103, USA. (Lippincott Williams and Wilkins - www.lww.com; Aids - journals.lww.com/aidsonline/pages/default.aspx)

Researchers from Karolinska University Hospital Detail Findings in Dysphagia (Relief of dysphagia during neoadjuvant treatment for cancer of the esophagus or gastroesophageal junction)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Digestive System Diseases and Conditions - Dysphagia have been published. According to news originating from Stockholm, Sweden, by NewsRx correspondents, research stated, "Dysphagia is the main symptom of cancer of the esophagus and gastroesophageal junction and causing nutritional problems and weight loss, often counteracted by insertion of self-expandable metal stents or nutrition via an enteral route. Clinical observations indicate that neoadjuvant therapy may effectively and promptly alleviate dysphagia, making such nutrition supportive interventions redundant before surgical resection."

Our news journalists obtained a quote from the research from Karolinska University Hospital, "The objective of the current study was to carefully study the effects of induction neoadjuvant therapy on dysphagia and its subsequent course and thereby investigate the actual need for alimentary gateways for nutritional support. Thirty-five consecutive patients scheduled for neoadjuvant therapy were recruited and assessed regarding dysphagia and appetite at baseline, after the first cycle of preoperative treatment with either chemotherapy alone or with chemoradiotherapy and before surgery. Platinum-based therapy in combination with 5-fluorouracil was administered intravenously days 1-5 every 3 weeks and consisted of three treatments. Patients receiving combined chemoradiotherapy started radiotherapy on day one of second chemotherapy cycle. They received fractions of 2 Gy/day each up to a total dose of 40 Gy. Watson and Ogilvie dysphagia scores were used to assess dysphagia, while appetite was assessed by the Edmonton Assessment System Visual analogue scale-appetite questionnaire. Patients were evaluated at regular outpatient clinic visits or by telephone. The histological tumor response in the surgical specimen was assessed using the Chirieac scale. Ten patients scheduled for neoadjuvant chemotherapy and 25 patients scheduled for chemoradiotherapy were included in the analysis. There was a significant improvement in dysphagia in both treatment groups, according to both scales, already from baseline to the completion of the first chemotherapy cycle which remained to the end of the neoadjuvant treatment (P < 0.001). Appetite also improved after the first chemotherapy cycle (P = 0.03). Body weight did not change during any type of neoadjuvant therapy. We were unable to demonstrate any association between relief of dysphagia and the degree of histological response to neoadjuvant therapy in the surgical specimen."

According to the news editors, the research concluded: "The present study shows that a platinum - 5FU-based neoadjuvant chemotherapy, with or without concomitant radiotherapy, effectively and promptly relieves dysphagia in patients presenting with cancers of the esophagus or gastroesophageal junction already after the first cycle."

For more information on this research see: Relief of dysphagia during neoadjuvant...
Researchers from Kashan University of Medical Sciences Report Recent Findings in Type 2 Diabetes (The effects of coenzyme Q10 administration on glucose homeostasis parameters, lipid profiles, biomarkers of inflammation and oxidative stress in ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Nutritional and Metabolic Diseases and Conditions - Type 2 Diabetes are presented in a new report. According to news reporting from Kashan, Iran, by NewsRx journalists, research stated, "Limited data are available indicating the effects of coenzyme Q10 (CoQ10) supplementation on metabolic status of patients with metabolic syndrome (MetS). The present study was conducted to determine the effects of CoQ10 administration on glucose homeostasis parameters, lipid profiles, biomarkers of inflammation and oxidative stress among patients with MetS."

The news correspondents obtained a quote from the research from the Kashan University of Medical Sciences, "This randomized, double-blind, placebo-controlled trial was performed among 60 overweight or obese and type 2 diabetes mellitus patients with coronary heart disease aged 40-85 years old. Participants were randomly allocated into two groups. Group A (n = 30) received 100 mg CoQ10 supplements and group B (n = 30) received placebo for 8 weeks. Fasting blood samples were taken at the beginning of the study and after 8-week intervention to quantify glucose homeostasis parameters, lipid profiles, biomarkers of inflammation and oxidative stress. Compared with the placebo, CoQ10 supplementation resulted in a significant reduction in serum insulin levels (-2.1 +/- A 7.1 vs. +4.1 +/- A 7.8 A mu IU/mL, P = 0.002) and homeostasis model of assessment-insulin resistance (-0.7 +/- A 2.1 vs. +1.0 +/- A 2.0, P = 0.002) and homeostatic model assessment-beta cell function (-5.9 +/- A 22.2 vs. +15.9 +/- A 34.0, P = 0.005). In addition, patients who received CoQ10 supplements had a significant increase in plasma total antioxidant capacity (TAC) concentrations (+26.0 +/- A 105.0 vs. -162.2 +/- A 361.8 mmol/L, P = 0.008) compared with the placebo group. However, after adjustment for the baseline levels, age and baseline BMI, the effect on TAC levels (P = 0.08) disappeared. Additionally, compared with the placebo group, a significant positive trends in plasma glutathione (P = 0.06) and a significant reduction in malondialdehyde (P = 0.08) were
seen among patients who received CoQ10 supplement. We did not observe any significant changes in fasting plasma glucose, lipid concentrations and inflammatory markers."

According to the news reporters, the research concluded: "Overall, daily intake of 100 mg CoQ10 supplements among patients with MetS for 8 weeks had beneficial effects on serum insulin levels, HOMA-IR, HOMA-B and plasma TAC concentrations. www.irct.ir http://www.irct.ir TargetType='URL' IRCT201502245623N35."

For more information on this research see: The effects of coenzyme Q10 administration on glucose homeostasis parameters, lipid profiles, biomarkers of inflammation and oxidative stress in patients with metabolic syndrome. Oncology - Lymphoma

Researchers from Kasturba Medical College Detail Findings in Lymphoma (Distribution of nodal lymphomas in a referral hospital of Mangalore city)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Oncology - Lymphoma. According to news reporting from Mangalore, India, by NewsRx journalists, research stated, "The distribution of different types of lymphoma varies across geographic regions. The present study was done to understand the occurrence of nodal lymphomas in a referral hospital of Mangalore city. Descriptive study."

The news correspondents obtained a quote from the research from Kasturba Medical College, "The present study was conducted on 95 lymph node biopsy specimens, received in a referral hospital of Mangalore city. All cases of nodal lymphoma diagnosed between January 2007 and June 2010 in a referral hospital of Mangalore were selected for the study. The patients age and clinical details were obtained. Immunophenotyping was done for all cases of NHL and selected cases of HL. IPI score for NHL was noted and correlated with the outcome. Chi square test was used. Out of the total 95 cases of nodal lymphoma 37 (39%) were HL while 58 (61%)
were NHL. Classical HL was diagnosed in 35 cases (37%) while 2 cases (2%) were diagnosed NLPHL. B cell lymphoma formed 72% of NHL. Follicular lymphoma accounted for 28% of all NHL. T cell lymphoma formed 28% of NHL. In conclusion the following points are significant about the distribution of lymphomas in a referral hospital of Mangalore city. The incidence of NSHL is higher while national data suggests MCHL as the most common subtype. The incidence of FL as well as T cell NHL is much higher when compared to national incidence."

According to the news reporters, the research concluded: "The epidemiological factors for this high frequency (either genetic or environmental) needs to be studied further."

For more information on this research see: Distribution of nodal lymphomas in a referral hospital of Mangalore city. Indian Journal of Cancer, 2015;52(4):557-61.

Our news journalists report that additional information may be obtained by contacting H. Zubair, Dept. of Pathology, Kasturba Medical College, Mangalore, India. Additional authors for this research include P.R. Muktha, S. Chakraborti and P.R Radha.

Researchers from Kerman University of Medical Sciences Report on Findings in Central Nervous System Agents (Chemical Composition, Anticonvulsant Activity, and Toxicity of Essential Oil and Methanolic Extract of Elettaria cardamomum)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Drugs and Therapies - Central Nervous System Agents. According to news reporting from Kerman, Iran, by NewsRx journalists, research stated, "Elettaria cardamomum is an aromatic spice (cardamom) native to the humid Asian areas, which contains some compounds with a potential anticonvulsant activity. Various pharmacological properties such as anti-inflammatory, analgesic, antioxidant, and antimicrobial effects have been related to this plant."

The news correspondents obtained a quote from the research from the Kerman University of Medical Sciences, "This research was conducted to examine the probable protective impact of the essential oil and methanolic extract of E. cardamomum against chemically (pentylentetrazole)and electrically (maximal electroshock)-induced seizures in mice. In addition, neurotoxicity, acute lethality, and phytochemistry of the essential oil and methanolic extract were estimated. The TLC method showed the presence of kaempferol, rutin, and quercetin in the extract, and the concentration of quercetin in the extract was 0.5 μg/mL. The major compounds in the essential oil were 1.8-cineole (45.6%), alpha-terpinyl acetate (33.7%), sabinene (3.8%), 4-terpinen-4-ol (2.4%), and myrcene (2.2%), respectively. The extract and essential oil showed significant neurotoxicity in the rotarod test at the doses of 1.5 g/kg and
0.75mL/kg, respectively. No mortalities were observed up to the doses of 2 g/kg and 0.75mL/kg for the extract and essential oil. The essential oil was effective in both the pentylentetrazole and maximal electroshock models; however, the extract was only effective in the pentylentetrazole model. The study suggested that E. cardamomum methanolic extract had no significant lethality in mice. Both the essential oil and methanolic extract showed movement toxicity.

According to the news reporters, the research concluded: "Anticonvulsant effects of E. cardamomum were negligible against the seizures induced by pentylentetrazole and maximal electroshock."

For more information on this research see: Chemical Composition, Anticonvulsant Activity, and Toxicity of Essential Oil and Methanolic Extract of Elettaria cardamomum. *Planta Medica*, 2016;82(17):1482-1486. *Planta Medica* can be contacted at: Georg Thieme Verlag Kg, Rudigerstr 14, D-70469 Stuttgart, Germany. **Oncology - Acute Lymphoblastic Leukemia**

**Researchers from King Abdul-Aziz University Detail Findings in Acute Lymphoblastic Leukemia (L-Asparaginase Isolated from Phaseolus vulgaris Seeds Exhibited Potent Anti-Acute Lymphoblastic Leukemia Effects In-Vitro and Low Immunogenic ...)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Oncology - Acute Lymphoblastic Leukemia are presented in a new report. According to news reporting from Jeddah, Saudi Arabia, by NewsRx journalists, research stated, "Escherichia coli-derived L-asparaginases have been used in the treatment of acute lymphoblastic leukemia (ALL), however, clinical hypersensitivity reactions and silent inactivation due to antibodies against E. coli-asparaginase, lead to inactivation of these preparations in most cases. Therefore, this study was aimed to investigate the cytotoxicity and antitumor effects of a novel L-asparaginase enzyme, isolated from Phaseolus vulgaris seeds (P-Asp) on the ALL cell line (Jurkat)."

The news correspondents obtained a quote from the research from King Abdul-Aziz University. "The immunogenicity of the enzyme was also evaluated in-vivo and results were compared to commercially available enzymes of microbial sources. The data demonstrated that P-Asp has an enhanced anti-proliferative effect on ALL cells as detected by the WST-8 cell viability assay kit. Cells treated with P-Asp also exhibited a higher degree of early apoptosis
compared with asparaginase from Escherichia coli (L-Asp) or its pegylated form Pegasparagase (PEG-ASP) that induced higher rates of late apoptosis and necrosis as detected by an Annexin V/Propidium iodide binding assay. In-vivo experiments indicated that mice treated with P-Asp had less distinct allergenic responses than other bacterial enzyme preparations as indicated by lower serum concentrations of IgG, IgE, IgM and mMCP-1 compared with other treated groups."

According to the news reporters, the research concluded: "P-Asp can be considered as a promising candidate for use in the treatment of ALL."

Our news journalists report that additional information may be obtained by contacting S.A. Mohamed, King Abdulaziz Univ, Dept. of Biochem, Fac Sci, Jeddah 21589, Saudi Arabia. Additional authors for this research include M.F. Elshal, T.A. Kumosani, A.M. Aldahlawi, T.A. Basbrain, F.A. Alshehri and H. Choudhry.

Drugs and Therapies - Antidepressants

Researchers from King's College Discuss Findings in Antidepressants [S-adenosyl methionine (SAMe) for depression in adults]

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Drugs and Therapies - Antidepressants is the subject of a report. According to news reporting from London, United Kingdom, by NewsRx journalists, research stated, "Depression is a recurrent illness with high rates of chronicity, treatment-resistance and significant economic impact. There is evidence in the literature that S-adenosyl methionine (SAMe), a naturally occurring compound in the human body, has antidepressant efficacy."

The news correspondents obtained a quote from the research from King's College, "This product may be an important addition to the armamentarium of antidepressant agents. To assess the effects of SAMe in comparison with placebo or antidepressants for the treatment of depression in adults. Search methods We searched the Cochrane Common Mental Disorders Group's Specialised Register (CCMDCTR Studies and Reference Register), MEDLINE, EMBASE, PsycINFO, international trial registers ClinicalTrials.gov and the World Health Organization trials portal (ICTRP). We checked reference lists, performed handsearching and contacted experts in the field. The CCMDCTR literature search was last updated on 5 February 2016. Selection criteria Randomised controlled trials comparing SAMe with placebo or antidepressants in adults with a diagnosis of major depression. Data collection and analysis Two authors independently performed extraction of data and assessment of risk of bias. We contacted trialists of included studies for additional information. This systematic review included eight trials comparing SAMe with either placebo, imipramine, desipramine or
escitalopram. We accepted trials that used SAMe as monotherapy or as add-on therapy to selective serotonin reuptake inhibitors (SSRIs), and we accepted both oral and parenteral administration. The review involved 934 adults, of both sexes, from inpatient and outpatient settings. The trials were at low risk of reporting bias. We judged the risk of selection, performance, detection and attrition bias as unclear or low, and one study was at high risk of attrition bias. There was no strong evidence of a difference in terms of change in depressive symptoms from baseline to end of treatment between SAMe and placebo as monotherapy (standardised mean difference (SMD) -0.54, 95% confidence interval (CI) -1.54 to 0.46; P = 0.29; 142 participants; 2 studies; very low quality evidence). There was also no strong evidence of a difference in terms of drop-out rates due to any reason between SAMe and placebo, when used as monotherapy (risk ratio (RR) 0.88, 95% CI 0.61 to 1.29; P = 0.52; 142 participants; 2 studies; low quality evidence). Low quality evidence showed that the change in depressive symptoms from baseline to end of treatment was similar between SAMe and imipramine, both as monotherapy (SMD -0.04, 95% CI -0.34 to 0.27; P = 0.82; 619 participants; 4 studies). There was also no strong evidence of a difference between SAMe and a tricyclic antidepressant in terms of drop-outs due to any reason (RR 0.61, 95% CI 0.28 to 1.31; P = 0.2; 78 participants; 3 studies; very low quality evidence). There was little evidence of a difference in terms of change in depressive symptoms from baseline to end of treatment between SAMe and escitalopram, both as monotherapy (MD 0.12, 95% CI -2.75 to 2.99; P = 0.93; 129 participants; 1 study; low quality evidence). There was no strong evidence of a difference between SAMe and escitalopram in terms of drop-outs due to any reason (RR 0.81, 95% CI 0.57 to 1.16; P = 0.26; 129 participants; 1 study; low quality evidence). There was low quality evidence that SAMe is superior to placebo as add-on to SSRIs in terms of change in depressive symptoms from baseline to end of treatment (MD -3.90, 95% CI -6.93 to -0.87; P = 0.01; 73 participants; 1 study). There was no strong evidence of a difference between SAMe and placebo as adjunctive therapy to an SSRI in terms of drop-outs due to any reason (RR 0.70, 95% CI 0.31 to 1.56; P = 0.38; 73 participants; 1 study; very low quality evidence). For all comparisons, secondary outcome measures of response and remission rates were consistent with these primary outcome measures. With regard to all extractable measures of the acceptability of SAMe, the quality of the evidence was low to very low. SAMe was not different from placebo and established antidepressants. The exception was that compared to imipramine, fewer participants experienced troublesome adverse effects when treated with parenteral SAMe. The specific adverse effects were not detailed in most of the included studies. There were two reports of mania/hypomania recorded for 441 participants in the SAMe arm. Authors’ conclusions Given the absence of high quality evidence and the inability to draw firm conclusions based on that evidence, the use of SAMe for the treatment of depression in adults should be investigated further. Future trials should be in the form of large randomised controlled clinical trials of high methodological quality, with particular attention given to randomisation, allocation concealment, blinding and the handling of missing data. Comparator antidepressants from all classes should be used."

According to the news reporters, the research concluded: "Adverse events should be detailed for each participant, bearing in mind that induction of mania is of particular interest."

For more information on this research see: S-adenosyl methionine (SAMe) for depression in adults. Cochrane Database of Systematic Reviews, 2016;(10):1451-1582. Cochrane Database of Systematic Reviews can be contacted at: Wiley-Blackwell, 111 River St, Hoboken 07030-5774, NJ, USA.

Researchers from Kirby Institute Provide Details of New Studies and Findings in the Area of HIV/AIDS (Hospitalization for Anxiety and Mood Disorders in HIV-Infected and -Uninfected Gay and Bisexual Men)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Immune System Diseases and Conditions - HIV/AIDS are presented in a new report. According to news reporting out of Sydney, Australia, by NewsRx editors, research stated, "Prevalence of anxiety and mood disorders (AMDs) in HIV-infected individuals has varied widely because of the variety of measurements used and differences in risk factor profiles between different populations. We aimed to examine the relationship between HIV status and hospitalization for AMDs in gay and bisexual men (GBM)."

Our news journalists obtained a quote from the research from Kirby Institute, "HIV-infected (n = 557) and HIV-uninfected (n = 1325) GBM recruited in Sydney, Australia were probabilistically linked to their hospital admissions and death notifications (2000-2012). Random-effects Poisson models were used to assess HIV risk factors for hospitalization. Cox regression methods were used to assess risk factors for mortality. We observed 300 hospitalizations for AMDs in 15.3% of HIV-infected and 181 in 5.4% of HIV-uninfected participants. Being infected with HIV was associated with a 2.5-fold increase in risk of hospitalization for AMDs in GBM. Other risk factors in the HIV-infected cohort included previous hospitalization for HIV-related dementia, a more recent HIV diagnosis, and a CD4 T-cell count above 350 cells per cubic millimeter. Being hospitalized for an AMD was associated with a 5.5-fold increased risk of mortality; this association did not differ by HIV status. An association between substance use and mortality was observed in individuals hospitalized for AMDs. There is a need to provide more effective strategies to identify and treat AMDs in HIV-infected GBM."

According to the news editors, the research concluded: "This research highlights the importance of further examination of the effects of substance use, neurocognitive decline, and AMDs on the health of HIV-infected individuals."

Our news journalists report that additional information may be obtained by
Researchers from Kitasato University Provide Details of New Studies and Findings in the Area of Cardiology (Contributions of Respiration and Heartbeat to the Pulmonary Blood Flow in the Fontan Circulation)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Cardiology have been presented. According to news reporting originating in Kanagawa, Japan, by NewsRx journalists, research stated, "In the Fontan circulation, driving forces with respiration, heartbeat, and lower limb muscle pump are relevant. However, the mechanics of these forces has not been proven, and their effects on the Fontan circulation remain unclear."

The news reporters obtained a quote from the research from Kitasato University, "We performed catheter examinations and measured pressure and flow velocity simultaneously in the bilateral pulmonary arteries of 12 Fontan patients 1 year after the operation. The pulmonary pressure and flow velocity data were decomposed into respiratory and heartbeat components by discrete Fourier analysis. We then calculated respiratory and cardiac wave intensity (WI) based on the respiratory and heartbeat components of pressure and flow velocity data. Respiratory WI formed 2 negative peaks, a backward expansion wave during the inspiratory phase, and then a backward compression wave during the expiratory phase. In 2 phrenic nerve palsy cases and 1 case of a patient on a respirator, respiratory WI showed disturbed patterns and a negative pattern, respectively. Cardiac WI showed 2 or 4 negative peaks, the time phase of which matched that of the atrial contractions. WI analysis elucidated that inspiration acts as a sucking driving force and increases the pulmonary blood flow in the Fontan circulation. Respiratory complications compromise efficiency in the Fontan circulation."

According to the news reporters, the research concluded: "It was also revealed that the pulmonary blood flow was mutually dammed up and sucked in by increases and decreases in atrial pressure."

Our news correspondents report that additional information may be obtained by contacting T. Honda, Kitasato University, Sch Med, Dept. of Cardiovasc Surg, Kanagawa, Japan. Additional authors for this research include K. Itatani, M. Takanashi, A. Kitagawa, H.
Researchers from Kobe University Detail Findings in Indomethacin Therapy (Preventative Effects of Sodium Alginate on Indomethacin-induced Small-intestinal Injury in Mice)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Drugs and Therapies - Indomethacin Therapy have been published. According to news reporting originating from Hyogo, Japan, by NewsRx correspondents, research stated, "Recent advances in diagnostic technologies have revealed that nonsteroidal anti-inflammatory drugs (NSAIDs) can cause serious mucosal injury in the upper and lower gastrointestinal tract (including the small intestine). A drug to treat NSAID-induced small-intestinal injury (SII) is lacking."

Our news editors obtained a quote from the research from Kobe University, "Sodium alginate is a soluble dietary fiber extracted from brown seaweed and its solution has been used as a hemostatic agent to treat gastrointestinal bleeding due to gastric ulcers. Whether sodium alginate has therapeutic effects on NSAID-induced SII and its mechanism of action are not known. Here, we investigated if administration of two forms (high-molecular-weight (HMW) and low-molecular-weight (LMW)) of sodium alginate could ameliorate indomethacin-induced SII. Pretreatment with HMW sodium alginate or LMW sodium alginate before indomethacin administration improved ulceration and the resultant intestinal shortening was associated with reduced histological severity of mucosal injury and ameliorated mRNA expression of inflammation-related molecules in the small intestine. We found that mRNAs of secretory Muc2 and membrane-associated Muc1, Muc3 and Muc4 were expressed in the small intestine. mRNA expression of Muc1-4 was increased in indomethacin-induced SII, and these increases were prevented by sodium alginate."

According to the news editors, the research concluded: "Thus, administration of sodium alginate could be a therapeutic approach to prevent indomethacin-induced SII."

For more information on this research see: Preventative Effects of Sodium Alginate on Indomethacin-induced Small-intestinal Injury in Mice. *International Journal of Medical Sciences*, 2016;13(9):653-663. *International Journal of Medical Sciences* can be contacted at: Ivyspring Int Publ, PO Box 4546, Lake Haven, Nsw 2263, Australia.

Researchers from Korea Institute of Radiological and Medical Sciences Provide Details of New Studies and Findings in the Area of Molecular Imaging (Detection of metastatic tumors after g-irradiation using longitudinal molecular imaging and gene ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Nanotechnology - Molecular Imaging are presented in a new report. According to news reporting from Seoul, South Korea, by NewsRx journalists, research stated, "A few recent reports have indicated that metastatic growth of several human cancer cells could be promoted by radiotherapy. C6-L cells expressing the firefly luciferase (fLuc) gene were implanted subcutaneously into the right thigh of BALB/c nu/nu mice."

The news correspondents obtained a quote from the research from the Korea Institute of Radiological and Medical Sciences, "C6-L xenograft mice were treated locally with 50-Gy g-irradiation (g-IR) in five 10-Gy fractions. Metastatic tumors were evaluated after g-IR by imaging techniques. Total RNA from non-irradiated primary tumor (NRPT), g-irradiated primary tumor (RPT), and three metastatic lung nodule was isolated and analyzed by microarray. Metastatic lung nodules were detected by BLI and PET/CT after 6-9 weeks of g-IR in 6 (17.1%) of the 35 mice. The images clearly demonstrated high [18F]FLT and [18F]FDG uptake into metastatic lung nodules. Whole mRNA expression patterns were analyzed by microarray to elucidate the changes among NRPT, RPT and metastatic lung nodules after g-IR. In particular, expression changes in the cancer stem cell markers were highly significant in RPT."

According to the news reporters, the research concluded: "We observed the metastatic tumors after g-IR in a tumor-bearing animal model using molecular imaging methods and analyzed the gene expression profile to elucidate genetic changes after g-IR."

Our news journalists report that additional information may be obtained by contacting S.J. Jang, Molecular Imaging Research Center, Korea Institute of Radiological and Medical Sciences (KIRAMS), Seoul 139-706, South Korea. Additional authors for this research include J.H. Kang, Y.J. Lee, K.I. Kim, T.S. Lee, J.G. Choe and S.M Lim.

Researchers from Korea University Ansan Hospital Report Details of New Studies and Findings in the Area of Peptic Ulcers (Risk of Vascular Thrombotic Events Following Discontinuation of Antithrombotics After Peptic Ulcer Bleeding)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Digestive System Diseases and Conditions - Peptic Ulcers. According to news reporting out of Gyeonggi Do, South Korea, by NewsRx editors, research stated, "To evaluate whether the risk of cardiovascular events increases when antithrombotics are discontinued after ulcer bleeding. Peptic ulcer bleeding associated with antithrombotics has increased due to the increase in the proportion of elderly population."

Our news journalists obtained a quote from the research from Korea University Ansan Hospital, "Little is known about the long-term effects of discontinuing antithrombotics after peptic ulcer bleeding. The aim of this study was to evaluate whether the risk of cardiovascular events increases when antithrombotics are discontinued after ulcer bleeding. We reviewed the medical records of patients with ulcer bleeding who were taking antiplatelet agents or anticoagulants at the time of ulcer bleeding. Cox-regression model was used to adjust for potential confounders, and analyzed association between discontinuation of antithrombotic drugs after ulcer bleeding and thrombotic events such as ischemic heart disease or stroke. Of the 544 patients with ulcer bleeding, 72 patients who were taking antithrombotics and followed up for >2 months were analyzed. Forty patients discontinued antithrombotics after ulcer bleeding (discontinuation group) and 32 patients continued antithrombotics with or without transient interruption (continuation group). Thrombotic events developed more often in discontinuation group than in the continuation group [7/32 (21.9%) vs. 1/40 (2.5%), p=0.019]. Hazard ratio for thrombotic event when antithrombotics were continuously discontinued was 10.9 (95% confidence interval, 1.3-89.7). There were no significant differences in recurrent bleeding events between the 2 groups. Discontinuation of antithrombotics after peptic ulcer bleeding increases the risk of cardiovascular events."

According to the news editors, the research concluded: "Therefore, caution should be taken when discontinuing antithrombotics after ulcer bleeding."

Our news journalists report that additional information may be obtained by contacting S.Y. Kim, Dept. of Internal Medicine, Division of Gastroenterology and Hepatology, Korea University College of Medicine, Korea University Ansan Hospital, Jeokgeum-ro, Danwon-gu, Ansan-si, Gyeonggi-do, Seoul, South Korea. Researchers from Kurume University Report Recent Findings in Hepatomas (Inhibition of hypoxia-inducible factor via upregulation of von Hippel-Lindau protein induces "angiogenic switch off" in a hepatoma mouse model)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Liver Diseases and Conditions - Hepatomas. According to news reporting originating from Fukuoka, Japan, by NewsRx correspondents, research stated, "Angiogenic switch off is one of the ideal therapeutic concepts in the treatment of cancer. However, the specific molecules which can induce 'angiogenic switch off' in tumor have not been identified yet."

Our news editors obtained a quote from the research from Kurume University, "In this study, we focused on von Hippel-Lindau protein (pVHL) in hepatocellular carcinoma (HCC) and investigated the effects of sulfoglycosyl-acylpropanediol (SQAP), a novel synthetic sulfoglycolipid, for HCC. We examined mutation ratio of VHL gene in HCC using 30 HCC samples and we treated the HCC-implanted mice with SQAP. Thirty clinical samples showed no VHL genetic mutation in HCC. SQAP significantly inhibited tumor growth by inhibiting angiogenesis in a hepatoma mouse model. SQAP induced tumor 'angiogenic switch off' by decreasing hypoxia-inducible factor (HIF)-1, 2 alpha protein via pVHL upregulation. pVHL upregulation decreased HIF alpha protein levels through different multiple mechanisms: (i) increasing pVHL-dependent HIF alpha protein degradation; (ii) decreasing HIF alpha synthesis with decrease of NF-kappa B expression; and (iii) decrease of tumor hypoxia by vascular normalization. We confirmed these antitumor effects of SQAP by the loss-of-function experiments."

According to the news editors, the research concluded: "We found that SQAP directly bound to and inhibited transglutaminase 2. This study provides evidence that upregulation of tumor pVHL is a promising target, which can induce 'angiogenic switch off' in HCC."

For more information on this research see: Inhibition of hypoxia-inducible factor via upregulation of von Hippel-Lindau protein induces "angiogenic switch off" in a hepatoma mouse model. *Molecular Therapy-Oncolytics*, 2015;2():1-11. *Molecular Therapy-Oncolytics* can be contacted at: Nature Publishing Group, 75 Varick St, 9TH Flr, New York, NY 10013-1917, USA.

Researchers from Kyoto University Describe Findings in CD Antigens (Regeneration of CD8 alpha beta T Cells from T-cell-Derived iPSC Imparts Potent Tumor Antigen-Specific Cytotoxicity)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Immunology - CD Antigens have been published. According to news reporting originating in Kyoto, Japan, by NewsRx journalists, research stated, "Although adoptive transfer of cytotoxic T lymphocytes (CTL) offer a promising cancer therapeutic direction, the generation of antigen-specific CTL from patients has faced difficulty in efficient expansion in ex vivo culture. To resolve this issue, several groups have proposed that induced pluripotent stem cell technology be applied for the expansion of antigen-specific CTL, which retain expression of the same T-cell receptor as original CTL."

The news reporters obtained a quote from the research from Kyoto University, "However, in these previous studies, the regenerated CTL are mostly of the CD8 alpha alpha(+) innate type and have less antigen-specific cytotoxic activity than primary CTL. Here we report that, by stimulating purified iPSC-derived CD4/CD8 double-positive cells with anti-CD3 antibody, T cells expressing CD8 alpha beta were generated and exhibited improved antigen-specific cytotoxicity compared with CD8 alpha alpha(+) CTL. Failure of CD8 alpha beta T-cell production using the previous method was found to be due to killing of double-positive cells by the double-negative cells in the mixed cultures. We found that WT1 tumor antigen-specific CTL regenerated by this method prolonged the survival of mice bearing WT1-expressing leukemic cells."

According to the news reporters, the research concluded: "Implementation of our methods may offer a useful clinical tool."

For more information on this research see: Regeneration of CD8 alpha beta T Cells from T-cell-Derived iPSC Imparts Potent Tumor Antigen-Specific Cytotoxicity. Cancer Research, 2016;76(23):6839-6850. Researchers from Kyoto University Discuss Findings in Microtubule-Associated Proteins (Microtubule density and landing rate as parameters to analyze tau protein in the MT-kinesin "gliding" assay)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Proteins - Microtubule-Associated Proteins is now available. According to news reporting originating in Kyoto, Japan, by NewsRx journalists, research stated, "Microtubule-associated protein (MAP) tau is a well-established hallmark of a large group of age related neurodegenerative diseases collectively called tauopathies. Under pathological conditions the equilibrium of tau binding to the MTs is perturbed, either by misregulation in the expression levels of specific tau isoforms or by MAPT gene mutations."

The news reporters obtained a quote from the research from Kyoto University, "Preclinical detection of such misregulated tau proteins in cerebrospinal fluid (CSF) is desirable for differential diagnosis and effective prognosis of neurodegeneration. Conventional tau protein detection methods utilize tau isoform-specific antibodies. Such immuno-based protocols, including enzyme-linked immunosorbent assay (ELISA) and Western blots have appropriate sensitivity and specificity, but often show high variability and are time consuming. Here, we established a non-immuno tau protein detection method utilizing microtubule (MT)-kinesin 'gliding' assay. All the six tau isoforms expressed in the human brain (ON3R, 1N3R, 2N3R, ON4R, 1N4R and 2N4R) and five MAPT gene mutants (V248L, G272V, P301L, V337M and R406W) were studied. The landing rate, binding density and gliding velocity of MTs with respect to each tau type were determined and are proposed as tau detection parameters. The detection parameters depicted the type of tau bound to the MTs. Furthermore, MT landing rate and density were found to be superior to gliding velocity in differentiating tau isoforms and mutants. The 3R vs. 4R isoforms, their admixtures, wild vs. mutant 2N4R and specific mutants were differentiated."

According to the news reporters, the research concluded: "Our data show that MT-kinesin gliding assay provides a convenient, lab-on-a-chip (LOC) compatible and antibody-free protocol for tau protein analysis."

For more information on this research see: Microtubule density and landing rate as parameters to analyze tau protein in the MT-kinesin "gliding" assay. Sensors and Actuators B-Chemical, 2017;238():954-961. Sensors and Actuators B-Chemical can be contacted at: Elsevier Science Sa, PO Box 564, 1001 Lausanne, Switzerland.

Researchers from Kyoto University Report New Studies and Findings in the Area of Type 2 Diabetes (Xanthoangelol and 4-Hydroxyderrcin Suppress Obesity-Induced Inflammatory Responses)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Nutritional and Metabolic Diseases and Conditions - Type 2 Diabetes have been presented. According to news reporting originating in Kyoto, Japan, by NewsRx journalists, research stated, "Obesity-induced inflammation plays a pivotal role in the pathogenesis of insulin resistance and type 2 diabetes. Xanthoangelol (XA) and 4-hydroxyderrcin (4-HD), phytochemicals extracted from Angelica keiskei, have been reported to possess various biological properties."

The news reporters obtained a quote from the research from Kyoto University, "Whether XA and 4-HD alleviate obesity-induced inflammation and inflammation-induced adipocyte dysfunction was investigated. For the in vitro study, a co-culture system composed of macrophages and adipocytes and macrophages stimulated with conditioned medium derived from fully differentiated adipocytes was conducted. For the in vivo study, mice were fed a high-fat diet supplemented with XA for 14 weeks. XA and 4-HD suppressed inflammatory factors in co-culture system. Moreover, treatment of RAW macrophages with XA and 4-HD moderated the suppression of uncoupling protein 1 promoter activity and gene expression in C3H10T1/2 adipocytes, which was induced by conditioned medium derived from LPS-stimulated RAW macrophages. Also, XA and 4-HD inhibited c-Jun N-terminal kinase phosphorylation, nuclear factor-kappa B, and activator protein 1, the last two being transcription activators in activated macrophages. Furthermore, in mice fed the high-fat diet, XA reduced inflammatory factors within the white adipose tissue."

According to the news reporters, the research concluded: "These results suggest that XA and 4-HD might be promising phytochemicals to suppress obesity-induced inflammation and inflammation-induced adipocyte dysfunction."

For more information on this research see: Xanthoangelol and 4-Hydroxyderrcin Suppress Obesity-Induced Inflammatory Responses. *Obesity, 2016;24(11):2351-2360. Researchers from Kyungpook National University Provide Details of New Studies and Findings in the Area of Phosphates (Suppressive effects of methylthiouracil on polyphosphate-mediated vascular inflammatory responses)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Phosphates are discussed in a new report. According to news reporting originating in Daegu, South Korea, by NewsRx journalists, research stated, "Drug repositioning is used to discover drug candidates to treat human diseases, through the application of drugs or compounds that are approved for the treatment of other diseases. This method can significantly reduce the time required and cost of discovering new drug candidates for human diseases."

Financial support for this research came from Ministry of Science, ICT and Future Planning.

The news reporters obtained a quote from the research from Kyungpook National University, "Previous studies have reported pro-inflammatory responses of endothelial cells to the release of polyphosphate (PolyP). In this study, we examined the anti-inflammatory responses and mechanisms of methylthiouracil (MTU), which is an antithyroid drug, and its effects on PolyP-induced septic activities in human umbilical vein endothelial cells (HUVECs) and mice. The survival rates, septic biomarker levels, behaviour of human neutrophils and vascular permeability were determined in PolyP-activated HUVECs and mice. MTU suppressed the PolyP-mediated vascular barrier permeability, up-regulation of inflammatory biomarkers, adhesion/migration of leucocytes, and activation and/or production of nuclear factor-kappa B, tumour necrosis factor-alpha and interleukin-6. Furthermore, MTU demonstrated protective effects on PolyP-mediated lethal death and the levels of the related septic biomarkers."

According to the news reporters, the research concluded: "Therefore, these results indicated the therapeutic potential of MTU on various systemic inflammatory diseases, such as sepsis or septic shock."

Our news correspondents report that additional information may be obtained by contacting M.C. Baek, Kyungpook National University, Sch Med, CMRI, Dept. of Mol Med, Daegu, South Korea. Additional authors for this research include S.K. Ku, S. Jeong, M.C. Baek and J.S. Bae.

Researchers from Kyushu University Report Findings in Chronic Kidney Disease (Cardiorenal Syndrome in End-Stage Kidney Disease)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Kidney Diseases and Conditions - Chronic Kidney Disease have been presented. According to news reporting from Fukuoka, Japan, by NewsRx journalists, research stated, "Cardiorenal syndrome (CRS) in patients with end-stage kidney disease (ESKD) represents mainly cardiovascular disease (CVD) due to various complications associated with renal dysfunction-defined as type 4 CRS by Ronco et al.-because the effect of cardiac dysfunction on the kidneys does not need to be taken into consideration, unlike in non-dialysis dependent chronic kidney disease (CKD). Patients with ESKD are often in a state of chronic inflammation due to the upregulation of proinflammatory cytokines."

The news correspondents obtained a quote from the research from Kyushu University, "Chronic inflammation leads to malnutrition and consequently to vascular endothelial dysfunction and vascular calcification, which is referred to as malnutrition-inflammation-atherosclerosis (MIA) syndrome and acts as a major risk factor for CVD. Anemia also plays a crucial role in CVD, and individuals with erythropoietin-resistant anemia have a particularly high risk of CVD. However, caution is emphasized because not only anemia itself, but also the overtreatment of anemia with erythropoiesis-stimulating agents aimed at elevating hemoglobin to (≥)13 g/dl can also increase the risk of CVD. In CKD-mineral and bone disorder (CKD-MBD), phosphate load triggers the interactions between various factors such as calcium, parathyroid hormone, vitamin D, and fibroblast growth factor 23, promoting vascular calcification and thus becoming a risk factor for CVD."

According to the news reporters, the research concluded: "In addition to traditional atherosclerosis risk factors such as hypertension, diabetes, and dyslipidemia, the involvement of MIA syndrome, anemia, and CKD-MBD accompanying CKD have also become a focus for investigation as major players in CRS in patients with ESKD."

Our news journalists report that additional information may be obtained by contacting K. Tsuruya, Dept. of Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan. Additional authors for this research include M. Eriuchi, S. Yamada, H. Hiraoka and T. Kitazono.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1159/000441583. This DOI is a link to an online electronic document that is either free or for purchase.

Researchers from Kyushu University Report New Studies and Findings in the Area of Multiple Sclerosis (Th1 cells downregulate connexin 43 gap junctions in astrocytes via microglial activation)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Autoimmune Diseases and Conditions - Multiple Sclerosis is now available. According to news originating from Fukuoka, Japan, by NewsRx correspondents, research stated, "We previously reported early and extensive loss of astrocytic connexin 43 (Cx43) in acute demyelinating lesions of multiple sclerosis (MS) patients. Because it is widely accepted that autoimmune T cells initiate MS lesions, we hypothesized that infiltrating T cells affect Cx43 expression in astrocytes, which contributes to MS lesion formation."

Our news journalists obtained a quote from the research from Kyushu University, "Primary mixed glial cell cultures were prepared from newborn mouse brains, and microglia were isolated by anti-CD11b antibody-conjugated magnetic beads. Next, we prepared astrocyte-rich cultures and astrocyte/microglia-mixed cultures. Treatment of primary mixed glial cell cultures with interferon (IFN)gamma, interleukin (IL)-4, or IL-17 showed that only IFN gamma or IL-17 at high concentrations reduced Cx43 protein levels. Upon treatment of astrocyte-rich cultures and astrocyte/microglia-mixed cultures with IFN gamma, Cx43 mRNA/protein levels and the function of gap junctions were reduced only in astrocyte/microglia-mixed cultures. IFN gamma-treated microglia-conditioned media and IL-1 beta, which was markedly increased in IFN gamma-treated microglia-conditioned media, reduced Cx43 protein levels in astrocyte-rich cultures. Finally, we confirmed that Th1 cell-conditioned medium decreased Cx43 protein levels in mixed glial cell cultures. These findings suggest that Th1 cell-derived IFN gamma activates microglia to release IL-1 beta that reduces Cx43 gap junctions in astrocytes."

According to the news editors, the research concluded: "Thus, Th1-dominant inflammatory states disrupt astrocytic intercellular communication and may exacerbate MS."

For more information on this research see: Scientific Reports, 2016;6():1-14. Scientific Reports can be contacted at: Nature Publishing Group, Macmillan Building, 4 Crinan St, London N1 9XW, England. (Nature Publishing Group - www.nature.com/; Scientific Reports - www.nature.com/srep/)

Researchers from La Trobe University Report Details of New Studies and Findings in the Area of Antimicrobial Cationic Peptides (Nicotiana alata Defensin Chimeras Reveal Differences in the Mechanism of Fungal and Tumor Cell Killing and an ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Membrane Proteins - Antimicrobial Cationic Peptides. According to news originating from Melbourne, Australia, by NewsRx correspondents, research stated, "The plant defensin NaD1 is a potent antifungal molecule that also targets tumor cells with a high efficiency. We examined the features of NaD1 that contribute to these two activities by producing a series of chimeras with NaD2, a defensin that has relatively poor activity against fungi and no activity against tumor cells."

Financial support for this research came from Australian Research Council (ARC).

Our news journalists obtained a quote from the research from La Trobe University, "All plant defensins have a common tertiary structure known as a cysteine-stabilized alpha-beta motif which consists of an alpha helix and a triple-stranded beta-sheet stabilized by four disulfide bonds. The chimeras were produced by replacing loops 1 to 7, the sequences between each of the conserved cysteine residues on NaD1, with the corresponding loops from NaD2. The loop 5 swap replaced the sequence motif (SKILRR) that mediates tight binding with phosphatidylinositol 4,5-bisphosphate [PI(4,5)P-2] and is essential for the potent cytotoxic effect of NaD1 on tumor cells. Consistent with previous reports, there was a strong correlation between PI(4,5)P-2 binding and the tumor cell killing activity of all of the chimeras. However, this correlation did not extend to antifungal activity. Some of the loop swap chimeras were efficient antifungal molecules, even though they bound poorly to PI(4,5)P-2, suggesting that additional mechanisms operate against fungal cells. Unexpectedly, the loop 1B swap chimera was 10 times more active than NaD1 against filamentous fungi."

According to the news editors, the research concluded: "This led to the conclusion that defensin loops have evolved as modular components that combine to make antifungal molecules with variable mechanisms of action and that artificial combinations of loops can increase antifungal activity compared to that of the natural variants."

For more information on this research see: Nicotiana alata Defensin Chimeras Reveal Differences in the Mechanism of Fungal and Tumor Cell Killing and an Enhanced Antifungal Variant. Antimicrobial Agents and Chemotherapy, 2016;60(10):6302-6312. Antimicrobial Agents and Chemotherapy can be contacted at: Amer Soc Microbiology, 1752 N St NW, Washington, DC 20036-2904, USA. (American Society for Microbiology - www.asm.org; Antimicrobial Agents and Chemotherapy - aac.asm.org)

The news correspondents report that additional information may be obtained from M.R. Bleackley, La Trobe University, La Trobe Inst Mol Sci, Dept. of Biochem & Genet, Melbourne, Vic, Australia. Researchers from Laboratory of Molecular Microbiology Report Details of New Studies and Findings in the Area of Rabies (Molecular optimization of rabies virus glycoprotein expression in Pichia pastoris)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Rhabdoviridae Infections - Rabies is the subject of a report. According to news reporting originating in Tunis, Tunisia, by NewsRx journalists, research stated, "In this work, different approaches were investigated to enhance the expression rabies virus glycoprotein (RABV-G) in the yeast Pichia pastoris; this membrane protein is responsible for the synthesis of rabies neutralizing antibodies. First, the impact of synonymous codon usage bias was examined and an optimized RABV-G gene was synthesized."

Financial support for this research came from Tunisian Ministry of Scientific Research and Higher Education.

The news reporters obtained a quote from the research from the Laboratory of Molecular Microbiology, "Nevertheless, data showed that the secretion of the optimized RABV-G gene was not tremendously increased as compared with the non-optimized one. In addition, similar levels of RABV-G were obtained when a-factor mating factor from Saccharomyces cerevisiae or the acid phosphatase PHO1 was used as a secretion signal. Therefore, sequence optimization and secretion signal were not the major bottlenecks for high-level expression of RABV-G in P. pastoris. Unfolded protein response (UPR) was induced in clones containing high copy number of RABV-G expression cassette indicating that folding was the limiting step for RABV-G secretion. To circumvent this limitation, co-overexpression of five factors involved in oxidative protein folding was investigated. Among these factors only PDI1, ERO1 and GPX1 proved their benefit to enhance the expression. The highest expression level of RABV-G reached 1230 ng ml(-1)."

According to the news reporters, the research concluded: "Competitive neutralizing assay confirmed that the recombinant protein was produced in the correct conformational form in this host."

Our news correspondents report that additional information may be obtained by contacting S. Ben Azoun, Laboratory of Molecular Microbiology, Vaccinology and Biotechnology Development, Biofermentation Unit, Institut Pasteur de Tunis, 13, place Pasteur BP 74, Tunis, 1002, Tunisia. Additional authors for this research include A.E. Belhaj, R. Gongrich, B. Gasser and H. Kallel.

**Oncology - Non-Small Cell Lung Cancer**

**Researchers from Leiden University Medical Center Describe Findings in Non-Small Cell Lung Cancer (The positive prognostic effect of stromal CD8+ tumor-infiltrating T cells is restrained by the expression of HLA-E in non-small cell lung ...)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Oncology - Non-Small Cell Lung Cancer. According to news reporting out of Leiden, Netherlands, by NewsRx editors, research stated, "Tumor-infiltrating CD8+ T cells are associated with improved clinical outcomes in non-small cell lung cancer (NSCLC). Here we studied their prognostic effect in the context of the expression of HLA molecules that are key in tumor recognition (HLA-A, B and C) or suppression of immunity (HLA-E) as this is still unknown."

Our news journalists obtained a quote from the research from Leiden University Medical Center, "Tumor tissue of 197 patients with resected pulmonary adenocarcinoma was analyzed for the presence of CD8+ T cells and the expression of b2-microglobulin, HLA-A, HLA-B/C and HLA-E. The relation of these parameters with overall survival (OS) was assessed. Loss and low expression of HLA-A or HLA-B/C was found in 44% and 75% of cases respectively. A high CD8+ tumor infiltration was strongly associated with clinical benefit only when the tumors retained good expression of HLA-A and HLA-B/C (p=0.004). In addition, more than 70% of the tumors were found to display a high expression of HLA-E. The expression of HLA-E by tumor cells was an independent negative prognostic factor for OS (p=0.031). Importantly, a dense stromal CD8+ T cell infiltration was strongly associated with improved OS only in HLA-E negative tumors (p=0.005) and its prognostic effect was completely abolished when tumors highly expressed HLA-E (p=0.989). CD8+ T cell infiltration strongly contributes to a better prognosis in NSCLC when the tumor cells retain the expression of classical HLA class I and do not express HLA-E."

According to the news editors, the research concluded: "Therefore, analysis of HLA-A, -B/C and HLA-E expression should be included as biomarkers to predict the response to immunotherapy."

For more information on this research see: The positive prognostic effect of stromal CD8+ tumor-infiltrating T cells is restrained by the expression of HLA-E in non-small cell lung carcinoma. *Oncotarget*, 2016;7(3):3477-88.

Our news journalists report that additional information may be obtained by contacting M. Talebian Yazdi, Dept. of Pulmonology, Leiden University Medical Center, Leiden, Netherlands. Additional authors for this research include S. van Riet, A. van Schadewijk, M. Fiocco, T. van Hall, C. Taube, P.S. Hiemstra and S.H van der Burg.
Researchers from Leonard Davis School of Gerontology Describe Findings in Alzheimer Disease (Interactions between inflammation, sex steroids, and Alzheimer's disease risk factors)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Neurodegenerative Diseases and Conditions - Alzheimer Disease have been presented. According to news reporting originating from Los Angeles, California, by NewsRx correspondents, research stated, "Alzheimer’s disease (AD) is an age-related neurodegenerative disorder for which there are no effective strategies to prevent or slow its progression. Because AD is multifactorial, recent research has focused on understanding interactions among the numerous risk factors and mechanisms underlying the disease."

Our news editors obtained a quote from the research from the Leonard Davis School of Gerontology, "One mechanism through which several risk factors may be acting is inflammation. AD is characterized by chronic inflammation that is observed before clinical onset of dementia. Several genetic and environmental risk factors for AD increase inflammation, including apolipoprotein E4, obesity, and air pollution. Additionally, sex steroid hormones appear to contribute to AD risk, with age-related losses of estrogens in women and androgens in men associated with increased risk. Importantly, sex steroid hormones have anti-inflammatory actions and can interact with several other AD risk factors."

According to the news editors, the research concluded: "This review examines the individual and interactive roles of inflammation and sex steroid hormones in AD, as well as their relationships with the AD risk factors apolipoprotein E4, obesity, and air pollution."

The news editors report that additional information may be obtained by contacting C.J. Pike, Univ Southern Calif, Leonard Davis Sch Gerontol, Los Angeles, CA 90089, United States. Additional authors for this research include V.A. Moser and C.J. Pike.

Researchers from Linkoping University Detail New Studies and Findings in the Area of Prostate Cancer (Predictors of early androgen deprivation treatment failure in prostate cancer with bone metastases)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Oncology - Prostate Cancer are presented in a new report. According to news reporting from Linkoping, Sweden, by NewsRx journalists, research stated, "Approximately 15% of men with hormone na?ve metastatic prostate cancer primarily fail to respond to androgen deprivation treatment (ADT). The reason why the response to ADT differs in this subgroup of men with prostate cancer remains unclear."

Financial supporters for this research include Ferring AB, Ferring Laegemidler A/S, Pharmacia AB, Schering-Plough AB.

The news correspondents obtained a quote from the research from Linkoping University, "The aim of this study was to describe the characteristics of these men and to thereby define predictors of early ADT failure in prostate cancer patients with bone metastases. The study was based on 915 men from the prospective randomized multicenter trial (no. 5) conducted by the Scandinavian Prostate Cancer Group comparing parenteral estrogen with total androgen blockade. Early ADT failure was defined as death from metastatic prostate cancer within 12?months after the start of ADT. Multivariate logistic regression models were applied to identify clinical predictors of early ADT failure. Ninety-four (10.3%) men were primarily nonresponders to ADT. Independent predictors of early ADT failure were poor Eastern Cooperative Oncology Group performance status (PS), analgesic consumption, low hemoglobin, and high Soloway score (extent of disease observed on the scan), in where patients with poor PS and/or high analgesic consumption had a threefold risk of early ADT failure. Not significantly factors related to early ADT failure were age, treatment, cardiovascular comorbidity, T category, grade of malignancy, serum estrogen level, and SHBG at enrolment. We analyzed characteristics of a subgroup of patients who primarily failed to respond to ADT."

According to the news reporters, the research concluded: "Four independent clinical predictors of early ADT failure could be defined, and men exhibiting these features should be considered for an alternative treatment."

Our news journalists report that additional information may be obtained by contacting E. Varenhorst, Dept. of Urology and Dept. of Clinical and Experimental Medicine, Linkoping University, Linkoping, Sweden. Additional authors for this research include R. Klaff, A. Berglund, P.O. Hedlund and G. Sandblom.

Researchers from Linkoping University Report New Studies and Findings in the Area of Quality of Life (Experiences of incontinence and pelvic floor muscle training after gynaecologic cancer treatment)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Quality of Life. According to news reporting from Linkoping, Sweden, by NewsRx journalists, research stated, "The purpose of the present study is to describe how gynaecological cancer survivors (GCS) experience incontinence in relation to quality of life, their possibilities for physical activity and exercise and their perceptions and experiences of pelvic floor muscle training. This qualitative interview content analysis study included 13 women (48-82 age) with urinary (n = 10) or faecal (n = 3) incontinence after radiation therapy (n = 2), surgery (n = 5) and surgery and radiation therapy (n = 6) for gynaecological cancer, 0.5-21 years ago."

Financial supporters for this research include The Swedish Cancer Society, The Kamprad Family Foundation for Entrepreneurship, Research and Charity, Region Ostergotland, Linkoping University, FORSS (The Research Council of Southeast Sweden).

The news correspondents obtained a quote from the research from Linkoping University. "Symptoms related to incontinence and restrictions in daily activities reduced physical quality of life. Emotions related to incontinence reduced psychological quality of life and social and existential quality of life, due to restrictions in activity and feelings of exclusion. Practical and mental strategies for maintaining quality of life were described, such as always bringing a change of clothes and accepting the situation. Possibilities for sexual and physical activity as well as exercise were also restricted by incontinence. The women had little or no experience of pelvic floor muscle training but have a positive attitude towards trying it. They also described a lack of information about the risk of incontinence. The women were willing to spend both money and time on an effective treatment for their incontinence. Nine out of 10 were willing to spend at least 7 h a week. GCS experienced that incontinence reduced quality of life and limited possibilities for sexual and physical activity as well as exercise. Coping strategies, both practical and emotional, facilitated living with incontinence. The women had a positive attitude towards pelvic floor muscle training."

According to the news reporters, the research concluded: "Lack of information had a negative impact on their way of dealing with the situation."

For more information on this research see: Experiences of incontinence and pelvic floor muscle training after gynaecologic cancer treatment. Supportive Care in Cancer, 2017;25 (1):157-166. Supportive Care in Cancer can be contacted at: Springer, 233 Spring St, New York, NY 10013, USA. (Springer - www.springer.com; Supportive Care in Cancer - www.springerlink.com/content/0941-4355/)

Researchers from Logan College of Chiropractic Report New Studies and Findings in the Area of Myeloid Cells (Progesterone Receptor-Mediated Actions Regulate Remodeling of the Cervix in Preparation for Preterm Parturition)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Myeloid Cells is the subject of a report. According to news reporting originating in Loma Linda, California, by NewsRx journalists, research stated, "This study determined whether a progesterone (P) receptor (PR)-mediated mechanism regulates morphological characteristics associated with prepartum cervix remodeling at term and with preterm birth. With focus on the transition from a soft to ripe cervix, the cervix stroma of untreated controls had reduced cell nuclei density/area and less organized extracellular collagen, while the density of macrophages/area, but not neutrophils, increased just 2 days before birth (day 17 vs day 15 or 16.5 postbreeding)."

The news reporters obtained a quote from the research from the Logan College of Chiropractic, "Preterm birth was induced within 24 hours of treatment on day 16 postbreeding with PR antagonist or ovariectomy (Ovx). Pure or mixed PR antagonists increased the density of macrophages in the cervix within 8 hours (day 16.5 postbreeding), in advance of preterm birth. However, neither PR antagonists nor P withdrawal after Ovx affected the densities of cell nuclei and neutrophils or extracellular collagen compared to the same day controls an indication that the cervix was sufficiently remodeled for birth to occur. To block the effect of systemic P withdrawal, Ovx pregnant mice were given a PR agonist, either pure or mixed. These treatments forestalled preterm birth and prevented further morphological remodeling of the cervix. The resulting increase in macrophage density in cervix stroma following Ovx was only blocked by a pure PR agonist."

According to the news reporters, the research concluded: "These findings support the hypothesis that inflammatory processes in the prepartum cervix that include residency of macrophages, cellular hypertrophy, and extracellular collagen structure are regulated by genomic actions of PR in a final common mechanism both at term and with induced preterm birth."

Our news correspondents report that additional information may be obtained by contacting S.M. Yellon, Loma Linda Logan College of Chiropractic, Sch Med, Dept. of Basic Sci, Div Physiol, Loma Linda, CA 92350, United States. Additional authors for this research

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1177/1933719116650756. This DOI is a link to an online electronic document that is either free or for purchase.

Oncology - Cancer Care

Researchers from London Health Sciences Center Describe Findings in Cancer Care (Patient- and family-centered care: a qualitative exploration of oncologist perspectives)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Oncology - Cancer Care have been presented. According to news reporting originating from London, Canada, by NewsRx correspondents, research stated, "Increasingly, patient- and family-centered care (PFCC) is recognized as a valuable component of healthcare reform with rich opportunities for improvement within oncology. Shifting toward PFCC requires physician buy-in; however, research examining their perspectives on PFCC is lacking."

Our news editors obtained a quote from the research from London Health Sciences Center, "We sought to explore oncologists' perspectives on PFCC to identify factors that influence their ability to practice PFCC. We conducted semi-structured interviews with 18 oncologists (8 radiation, 4 medical, 4 surgical, 2 hematologist-oncologists) at a single Canadian academic cancer institution. Interview data were analyzed using thematic analysis and principles drawn from grounded theory. Subsequently, focus groups consisting of the interviewed participants were facilitated to confirm and elaborate on our findings. Constant comparisons were used to identify recurring themes. Three dominant themes emerged. First, physicians displayed cautious engagement in their approach to PFCC. We conducted semi-structured interviews with 18 oncologists. Collectively, participants understood the general principles of PFCC. However, there was a limited understanding of the value, implications, and motivation for improving PFCC which may create reluctance with physician buy-in. Second, both individual and system barriers to practicing PFCC were identified. A lack of physician acknowledgement and engagement and competing responsibilities emerged as provider-level challenges. System barriers included impaired clinic workflow, physical infrastructure constraints, and delays in access to care. Third, physicians were able to identify existing and potential PFCC behaviors that were feasible within existing system constraints."

According to the news editors, the research concluded: "Advancing PFCC will require continued physician education regarding the value of PFCC, acknowledgement and preservation of effective patient- and family-centered strategies, and creative solutions to address the system constraints to delivering PFCC."
For more information on this research see: Patient- and family-centered care: a qualitative exploration of oncologist perspectives. *Supportive Care in Cancer*, 2017;25(1):213-219. *Supportive Care in Cancer* can be contacted at: Springer, 233 Spring St, New York, NY 10013, USA. **Clinical Research - Clinical Trials and Studies**

Researchers from Maastricht University Report New Studies and Findings in the Area of Clinical Trials and Studies [Time-to-event versus ten-year-absolute-risk in cardiovascular risk prevention - does it make a difference? Results from the ...]

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Clinical Research - Clinical Trials and Studies have been published. According to news originating from Maastricht, Netherlands, by NewsRx correspondents, research stated, "The concept of shared-decision-making is a well-established approach to increase the participation of patients in medical decisions. Using lifetime risk or time-to-event (TTE) formats has been increasingly suggested as they might have advantages, e.g. in younger patients, to better show consequences of unhealthy behaviour."

Our news journalists obtained a quote from the research from Maastricht University, "In this study, the most-popular ten-year risk illustration in the decision-aid-software arriba™ (emoticons), is compared within a randomised trial to a new-developed TTE illustration, which is based on a Markov model. Thirty-two General Practitioners (GPs) took part in the study. A total of 304 patients were recruited and counseled by their GPs with arriba™, and randomized to either the emoticons or the TTE illustration, followed by a patient questionnaire to figure out the degree of shared-decision-making (PEF-FB9, German questionnaire to measure the participation in the shared decision-making process, primary outcome), as well as the decisional conflict, perceived risk, accessibility and the degree of information, which are all secondary outcomes. Regarding our primary outcome PEF-FB9 the new TTE illustration is not inferior compared to the well-established emoticons taking the whole study population into account. Furthermore, the non-inferiority of the innovative TTE could be confirmed for all secondary outcome variables. The explorative analysis indicates even advantages in younger patients (below 46 years of age). The TTE format seems to be as useful as the well-established emoticons. For certain patient populations, especially younger patients, the TTE may be even superior to demonstrate a cardiovascular risk at early stages."

According to the news editors, the research concluded: "Our results suggest that
time-to-event illustrations should be considered for current decision support tools covering cardiovascular prevention."

The news correspondents report that additional information may be obtained from C.C. Adarkwah, Maastricht University, CAPHRI Sch Public Hlth & Primary Care, Dept. of Hlth Serv Res, Maastricht, Netherlands. Additional authors for this research include N. Jegan, M. Heinzel-Gutenbrunner, F. Kuhne, U. Siebert, U. Popert, N. Donner-Banzhoff and S. Kurwitz.

Researchers from Maharishi Markandeshwar University Report New Studies and Findings in the Area of Melanoma (Immunogenic decapptide in melanoma immunotherapy)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Oncology - Melanoma. According to news reporting originating from Haryana, India, by NewsRx correspondents, research stated, "Melanoma is a cancer associated with melanocytes of epidermis. There has been a consistent increase in the number of melanoma patients because of the depletion of the ozone layer which makes it of paramount importance to explore the immunogenic potential of various peptides in melanoma therapy."

Our news editors obtained a quote from the research from Maharishi Markandeshwar University, "In the current study, a mutated decapptide (ELAGIGILTV) epitope ID 12941 was taken from the melanoma antigen recognized by T-cells. This epitope displayed relatively better affinity for histocompatibility leukocyte antigen influencing the proliferation of cytotoxic T-cells. Immunogenicity of the oligopeptide can be further intensified by its simultaneous binding to the programmed death receptor of the T lymphocytes. We have used the molecular dynamics (MD) simulation approach to reveal the dynamics of the decapptide and its consequences to immunogenic effects. The dynamics have ensembled various conformations of the peptide which have been clustered in their representative conformers. During the dynamics, the peptide was found to fold to its conformation with a minimum free energy. Moreover, multiple analysis of the MD trajectory has provided many physiochemical features involved in the biological activity to improve the immunogenicity of this antigenic peptide."

According to the news editors, the research concluded: "The manuscript concludes by proposing this decapptide as a potential vaccine for the melanoma cancer."

For more information on this research see: Immunogenic decapptide in melanoma immunotherapy. *Journal of Molecular Modeling*, 2016;22(11):133-139. *Journal of Molecular
Researchers from Mahidol University Report on Findings in Anterior Pituitary Hormones (Prolactin receptor and osteogenic induction of prolactin in human periodontal ligament fibroblasts)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Hormones - Anterior Pituitary Hormones. According to news reporting from Bangkok, Thailand, by NewsRx journalists, research stated, "Prolactin is an important hormone involved in the interaction between maternal, extraembryonic, and fetal tissues that remains in high levels during the entire duration of pregnancy. Although many systemic alterations occur during pregnancy, such as hormonal changes, that are known to be associated with periodontitis and tooth loss, PRL function in human periodontal ligament fibroblasts (HPDLF) had never been studied."

Financial supporters for this research include Thailand Research Fund, Mahidol University, Office of Higher Education Commission under the National Research Universities Initiative.

The news correspondents obtained a quote from the research from Mahidol University, "Herein, we investigated the role of PRL in the regulation of HPDLF proliferation and differentiation. HPDLF were cultured in differentiating medium with various concentrations of PRL. The present study demonstrated that HPDLF and primary human PDL cells that were extracted for orthodontic purpose expressed both short and long isoforms of PRLR mRNA and its proteins. An incubation with of high concentration of PRL (600 and 1,000 ng/mL) modestly decreased the HPDLF number. In contrast, PRL at a non-reproductive level (10 ng/mL) and pregnant level (100 ng/mL) significantly upregulated the markers of osteogenesis, such as RUNX2, BMP2, and POSTN, but not SOX9. Mineral nodule formation was induced, whereas proteoglycan accumulation was reduced by PRL suggesting that HPDLF were undergoing differentiation into preosteoblastic cells."

According to the news reporters, the research concluded: "The presence of hPRLR in human PDL together with PRL-induced upregulation of osteogenic markers strongly suggested a direct regulatory role of PRL in PDL and periodontal tissue development."

Researchers from Manipal University Report Recent Findings in Central Nervous System Stimulants [Standardised extract of safed musli (Chlorophytum borivilianum) increases aphrodisiac potential besides being safe in male Wistar rats]

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Drugs and Therapies - Central Nervous System Stimulants have been published. According to news reporting from Karnataka, India, by NewsRx journalists, research stated, "The standardised extract of root of safed musli (Chlorophytum borivilianum) was evaluated for its aphrodisiac potential and safety profile on reproductive system. Wistar albino rats were trained to provide sexual experience under a dim red light (10 W) in a glass tank."

The news correspondents obtained a quote from the research from Manipal University. "Male and female rats were placed periodically in the glass tank in a particular order, that is male followed by introduction of the receptive female. Dosing of extract was carried out for 54 days at 125 and 250 mg kg(-1) p.o to male rats. On 14th and 28th days, the animals were observed from the cage side for sexual behaviours. Safed musli at both dose levels enhanced sexual vigour and libido which might be useful for treatment of sexual dysfunction in male till 28th day. Safety profile was assessed after 54 days of drug treatment, where both doses showed an increase in sperm count and increase in sperm motility. Thus, it can be stated that both doses possessed the spermatogenic potential, which would be highly beneficial in treating oligospermia or low sperm count."

According to the news reporters, the research concluded: "After 54 days of study, there was increase in sperm abnormality (%) at both doses, but not more than 10%, which indicated that this formulation will not induce infertility."

Our news journalists report that additional information may be obtained by
Researchers from Mayo Clinic Report Details of New Studies and Findings in the Area of Endometrial Cancer (Disparities in Surgical Care Among Women With Endometrial Cancer)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Oncology - Endometrial Cancer. According to news reporting from Rochester, Minnesota, by NewsRx journalists, research stated, "To analyze contemporary U.S. use of minimally invasive surgery for the treatment of endometrial cancer and associated inpatient complications and costs. In this retrospective cohort study, the National Inpatient Sample database was analyzed in patients with nonmetastatic endometrial cancer who underwent hysterectomy during 2012-2013."

The news correspondents obtained a quote from the research from Mayo Clinic, "Hierarchical multiple logistic regression and propensity score matching were used to compare complications among patients treated with open compared with minimally invasive hysterectomy surgery. Cost of care was also compared using generalized linear modeling. We identified 9,799 patients; 52.4% underwent open and 47.6% minimally invasive hysterectomy. Many patients (43.4%) were treated at low-volume hospitals (less than 10 endometrial cancer cases annually). Patients were less likely to undergo open surgery in high-volume compared with low-volume hospitals (51.8% compared with 58.1%, respectively; adjusted odds ratio [OR] 0.35, 95% confidence interval [CI] 0.13-0.94) and more likely to undergo open surgery in rural compared with urban teaching hospitals (75.6% compared with 51.1%, respectively; adjusted OR 14.34, 95% CI 9.66-21.27), government compared with nonprofit hospitals (61.3% compared with 51.1%, respectively; adjusted OR 1.66, 95% CI 1.15-2.39), and 'other' race (60.5%; adjusted OR 2.39, 95% CI 1.99-2.87) compared with white race (49.2%, referent). Open surgery was associated with increased perioperative complications (adjusted OR 2.80, 95% CI 2.48-3.17) and a $1,243 increase in cost per case compared with-minimally invasive approaches (P <.001). Using minimally invasive surgery for 80% of study patients may have averted 2,733 complications and saved approximately $19 million. Most U.S. women with endometrial cancer continue to be treated with open hysterectomy surgery despite increased complication rates and financial costs associated with this approach."

According to the news reporters, the research concluded: "A disparity in endometrial cancer surgical care exists that is affected by patient race and hospital geography and cancer volumes."

For more information on this research see: Disparities in Surgical Care Among Women With Endometrial Cancer. *Obstetrics and Gynecology*, 2016;128(3):526-534. *Obstetrics and Gynecology* can be contacted at: Lippincott Williams & Wilkins, Two Commerce Sq, 2001 Market St, Philadelphia, PA 19103, USA. (Lippincott Williams and
Researchers from Mayo Clinic Report Recent Findings in Heart Disease (Association between coronary microvascular function and the vasa vasorum in patients with early coronary artery disease)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Heart Disorders and Diseases - Heart Disease is the subject of a report. According to news originating from Rochester, Minnesota, by NewsRx correspondents, research stated, "The vasa vasorum (VV) plays a role in the initial phase of atherosclerosis, and abnormalities in microvascular function may be sensitive measures of the early development of atherosclerosis. The current study was designed to access the association between coronary microvascular function and VV density in patients undergoing cardiac catheterization."

Our news journalists obtained a quote from the research from Mayo Clinic, "Twenty-four patients with early coronary artery disease underwent endothelium-dependent (coronary blood flow, CBF) and endothelium-independent (coronary flow velocity reserve, CFVR) coronary microvascular function testing, and optical coherence tomography (OCT) imaging of the left anterior descending coronary artery (LAD). Using an intracoronary Doppler guidewire, CBF was examined by evaluating changes in blood flow in response to acetylcholine and CFVR in response to adenosine. VV density (VV volume/vessel volume x 100, % VV) of the proximal 10 mm of the LAD was quantified by OCT. The median values (Q1, Q3) of CFVR, % changes in CBF in response to acetylcholine, and the % VV were 2.70 (2.30, 2.90), -16.82 (-42.34, 54.52), and 2.62 (2.35, 3.35), respectively. % VV correlated inversely with CBF (r = -0.614, p = 0.001) and directly with CFVR (r = 0.423, p = 0.040). Multivariate analysis showed that only % VV was significantly correlated with CBF and the association was independent of other clinical variables, Framingham risk score, body mass index, and a family history of coronary heart disease. This study demonstrates that VV density has negative correlation with endothelium-dependent microvascular function in patients with early coronary atherosclerosis."

According to the news editors, the research concluded: "These observations link adventitial VV structure and function to microvascular dysfunction in early coronary atherosclerosis."

For more information on this research see: Association between coronary microvascular function and the vasa vasorum in patients with early coronary artery disease.
Researchers from McGill University Discuss Findings in Cell Biology (Genetic Drivers of Epigenetic and Transcriptional Variation in Human Immune Cells)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Life Science Research - Cell Biology have been published. According to news reporting originating from Montreal, Canada, by NewsRx correspondents, research stated, "Characterizing the multifaceted contribution of genetic and epigenetic factors to disease phenotypes is a major challenge in human genetics and medicine. We carried out high-resolution genetic, epigenetic, and transcriptomic profiling in three major human immune cell types (CD14(+) monocytes, CD16(+) neutrophils, and naive CD4(+) T cells) from up to 197 individuals."

Our news editors obtained a quote from the research from McGill University, "We assess, quantitatively, the relative contribution of cis-genetic and epigenetic factors to transcription and evaluate their impact as potential sources of confounding in epigenome-wide association studies. Further, we characterize highly coordinated genetic effects on gene expression, methylation, and histone variation through quantitative trait locus (QTL) mapping and allele-specific (AS) analyses. Finally, we demonstrate colocalization of molecular trait QTLs at 345 unique immune disease loci."

According to the news editors, the research concluded: "This expansive, high-resolution atlas of multi-omics changes yields insights into cell-type-specific correlation between diverse genomic inputs, more generalizable correlations between these inputs, and defines molecular events that may underpin complex disease risk."

For more information on this research see: Genetic Drivers of Epigenetic and Transcriptional Variation in Human Immune Cells. Cell, 2016;167(5):1398-1414,521-544. Cell can be contacted at: Cell Press, 600 Technology Square, 5TH Floor, Cambridge, MA 02139, USA. (Elsevier - www.elsevier.com; Cell - www.journals.elsevier.com/cell/)

The news editors report that additional information may be obtained by contacting T.
Researchers from McGill University Discuss Findings in Pharmacology
[D-Lysergic Acid Diethylamide (LSD) as a Model of Psychosis: Mechanism of Action and Pharmacology]

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Pharmacology have been published. According to news originating from Montreal, Canada, by NewsRx correspondents, research stated, "D-Lysergic Acid Diethylamide (LSD) is known for its hallucinogenic properties and psychotic-like symptoms, especially at high doses. It is indeed used as a pharmacological model of psychosis in preclinical research."

Our news journalists obtained a quote from the research from McGill University, "The goal of this review was to understand the mechanism of action of psychotic-like effects of LSD. We searched Pubmed, Web of Science, Scopus, Google Scholar and articles' reference lists for preclinical studies regarding the mechanism of action involved in the psychotic-like effects induced by LSD. LSD's mechanism of action is pleiotropic, primarily mediated by the serotonergic system in the Dorsal Raphe, binding the 5-HT2A receptor as a partial agonist and 5-HT1A as an agonist. LSD also modulates the Ventral Tegmental Area, at higher doses, by stimulating dopamine D-2, Trace Amine Associate receptor 1 (TAAR(1)) and 5-HT2A. More studies clarifying the mechanism of action of the psychotic-like symptoms or psychosis induced by LSD in humans are needed. LSD's effects are mediated by a pleiotropic mechanism involving serotonergic, dopaminergic, and glutamatergic neurotransmission."

According to the news editors, the research concluded: "Thus, the LSD-induced psychosis is a useful model to test the therapeutic efficacy of potential novel antipsychotic drugs, particularly drugs with dual serotonergic and dopaminergic (DA) mechanism or acting on TAAR(1) receptors."

For more information on this research see: D-Lysergic Acid Diethylamide (LSD) as a Model of Psychosis: Mechanism of Action and Pharmacology. International Journal of Molecular Sciences. 2016;17(11):2676-2695. International Journal of Molecular Sciences can be contacted at: Mdpi Ag, St Alban-Anlage 66, Ch-4052 Basel, Switzerland.

The news correspondents report that additional information may be obtained from D. De Gregorio, McGill University, Neurobiol Psychiat Unit, Montreal, PQ H3A 1A1, Canada. Additional authors for this research include S. Comai, L. Posa and G. Gobbi.
Researchers from McMaster University Describe Findings in Coumarins and Indandiones (Bleeding with direct oral anticoagulants vs warfarin: clinical experience)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Drugs and Therapies - Coumarins and Indandiones. According to news reporting from Hamilton, Canada, by NewsRx journalists, research stated, "The risk of bleeding in the setting of anticoagulant therapy continues to be re-evaluated following the introduction of a new generation of direct oral anticoagulants (DOACs)."

The news correspondents obtained a quote from the research from McMaster University, " Interruption of DOAC therapy and supportive care may be sufficient for the management of patients who present with mild or moderate bleeding, but in those with life-threatening bleeding, a specific reversal agent is desirable."

According to the news reporters, the research concluded: "We review the phase 3 clinical studies of dabigatran, rivaroxaban, apixaban, and edoxaban in patients with nonvalvular atrial fibrillation, in the context of bleeding risk and management."

Our news journalists report that additional information may be obtained by contacting J. Eikelboom, McMaster University, Div Hematol & Thromboembolism, Dept. of Med, Hamilton, ON, Canada.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1016/j.ajem.2016.09.046. This DOI is a link to an online electronic document that is either free or for purchase.

Researchers from McMaster University Discuss Findings in Celiac Disease (Duodenal Bacteria From Patients With Celiac Disease and Healthy Subjects Distinctly Affect Gluten Breakdown and Immunogenicity)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Nutritional and Metabolic Diseases and Conditions - Celiac Disease. According to news reporting originating in Hamilton, Canada, by NewsRx journalists, research stated, "Partially degraded gluten peptides from cereals trigger celiac disease (CD), an autoimmune enteropathy occurring in genetically susceptible persons. Susceptibility genes are necessary but not sufficient to induce CD, and additional environmental factors related to unfavorable alterations in the microbiota have been proposed."

The news reporters obtained a quote from the research from McMaster University, "We investigated gluten metabolism by opportunistic pathogens and commensal duodenal bacteria and characterized the capacity of the produced peptides to activate gluten-specific T-cells from CD patients. We colonized germ-free C57BL/6 mice with bacteria isolated from the small intestine of CD patients or healthy controls, selected for their in vitro gluten-degrading capacity. After gluten gavage, gliadin amount and proteolytic activities were measured in intestinal contents. Peptides produced by bacteria used in mouse colonizations from the immunogenic 33-mer gluten peptide were characterized by liquid chromatography tandem mass spectrometry and their immunogenic potential was evaluated using peripheral blood mononuclear cells from celiac patients after receiving a 3-day gluten challenge. Bacterial colonizations produced distinct gluten-degradation patterns in the mouse small intestine. Pseudomonas aeruginosa, an opportunistic pathogen from CD patients, exhibited elastase activity and produced peptides that better translocated the mouse intestinal barrier. P aeruginosa - modified gluten peptides activated gluten-specific T-cells from CD patients. In contrast, Lactobacillus spp. from the duodenum of non-CD controls degraded gluten peptides produced by human and P aeruginosa proteases, reducing their immunogenicity. Small intestinal bacteria exhibit distinct gluten metabolic patterns in vivo, increasing or reducing gluten peptide immunogenicity."

According to the news reporters, the research concluded: "This microbe - gluten - host interaction may modulate autoimmune risk in genetically susceptible persons and may underlie the reported association of dysbiosis and CD."

For more information on this research see: Duodenal Bacteria From Patients With Celiac Disease and Healthy Subjects Distinctly Affect Gluten Breakdown and Immunogenicity. Gastroenterology, 2016;151(4):670-683. Gastroenterology can be contacted at: W B Saunders Co-Elsevier Inc. 1600 John F Kennedy Boulevard, Ste 1800, Philadelphia, PA 19103-2899, USA. Researchers from Medical College Describe Findings in Medulloblastomas (An analysis of medulloblastoma: 10 year experience of a referral institution in South India)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Oncology - Medulloblastomas. According to news reporting from Tamil Nadu, India, by NewsRx journalists, research stated, "Medulloblastoma is an embryonal tumor with aggressive behavior and is more commonly seen in children than adults. The aim of this study was to determine the epidemiological patterns of medulloblastoma in a tertiary care center in Southern India."

The news correspondents obtained a quote from the research from Medical College, "It is a retrospective study, in which the records of all the clinically diagnosed medulloblastoma cases in the last 10 years (2002-2012) were analyzed. A total of 58 cases were found, with the mean age at diagnosis being 10 years. There was a slight predilection for the male sex (58.62%). The first presenting symptom was mostly related to raise intracranial pressure and the mean duration of symptoms was 200 days. Nearly, 89.6% of patients were in Stage 0 and had a central tumor location. Multimodality treatment included surgery followed by craniospinal irradiation up to 36 gray followed by posterior fossa boost up to 54 gray. Median radiation therapy duration was 6.5 weeks and concurrent single agent vincristine was the most common chemotherapy used. Most of the patients showed only a partial response to treatment, mainly because of large tumors at presentation, which could be attributed to the lack of awareness, delayed medical attention and poor follow-up. Early diagnosis and treatment is the key to management of medulloblastoma, which still needs to be achieved. Bulky tumors have a poor outcome, efforts should be aimed at complete surgery and giving risk stratification based treatment."

According to the news reporters, the research concluded: "Resources need to be allocated to make more conformal methods of radiotherapy available, which will decrease the growth abnormalities and cognitive impairments."

Our news journalists report that additional information may be obtained by contacting S. Gaur, Dept. of Radiation Oncology, Barnard Institute of Radiation Oncology, Rajiv Gandhi Government General Hospital and Madras Medical College, Chennai, Tamil Nadu, India. Additional authors for this research include S.S. Kumar and P. Balasubramaniam.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.4103/0019-509X.178404. This DOI is a link to an online electronic document that is either free or for purchase.

Keywords for this news article include: Asia, India, Surgery, Oncology, Tamil Nadu, Epidemiology, Medulloblastomas.
Researchers from Medical College Detail Findings in Cholinergic Muscle Stimulants [Hopeahainol A binds reversibly at the acetylcholinesterase (AChE) peripheral site and inhibits enzyme activity with a novel higher order concentration dependence]

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Drugs and Therapies - Cholinergic Muscle Stimulants have been published. According to news originating from Jacksonville, Florida, by NewsRx correspondents, research stated, "Natural product inhibitors of AChE are of interest both because they offer promise as inexpensive drugs for symptomatic relief in Alzheimer's disease and because they may provide insights into the structural features of the AChE catalytic site. Hopeahainol A is an uncharged polyphenol AChE inhibitor from the stem bark of Hopea hainanensis with a constrained, partially dearomatized bicyclic core."

Financial supporters for this research include Columbia University, National Institutes of Health, Bristol-Myers Squibb, Eli Lilly, Research Corporation for Science Advancement.

Our news journalists obtained a quote from the research from Medical College, "Molecular modeling indicates that hopeahainol A binds at the entrance of the long but narrow AChE active site gorge because it is too bulky to be accommodated within the gorge without severe distortion of the gorge as depicted in AChE crystal structures. We conducted inhibitor competition experiments in which AChE inhibition was measured with hopeahainol A together with either edrophonium (which binds at the base of the gorge) or thioflavin T (which binds to the peripheral or P-site near the gorge mouth). The results agreed with the molecular modeling and indicated that hopeahainol A at lower concentrations (< 200 μM) bound only to the P-site, as hopeahainol A and thioflavin T were unable to form a ternary complex with AChE while hopeahainol A and edrophonium did form a ternary complex with essentially no competition between them. Inhibition increased to a striking extent at higher concentrations of hopeahainol A, with plots analogous to classic Dixon plots showing a dependence on hopeahainol A concentrations to the third- or fourth order. The inhibition at higher hopeahainol A concentrations was completely reversed on dilution and blocked by bound edrophonium."

According to the news editors, the research concluded: "We hypothesize that bound hopeahainol A induces conformational changes in the AChE active site that allow binding of additional hopeahainol A molecules, a phenomenon that would be unprecedented for a reversible inhibitor that apparently forms no covalent bonds with AChE."

For more information on this research see: Hopeahainol A binds reversibly at the acetylcholinesterase (AChE) peripheral site and inhibits enzyme activity with a novel higher order concentration dependence. Chemico-Biological Interactions, 2016;259():78-84. Chemico-Biological Interactions can be contacted at: Elsevier Ireland Ltd, Elsevier House, Brookvale Plaza, East Park Shannon, Co, Clare, 00000, Ireland. (Elsevier - www.elsevier.com; Chemico-Biological Interactions - www.journals.elsevier.com/chemico-biological-interactions/)

The news correspondents report that additional information may be obtained from T.L. Rosenberry, Mayo Clinic, Dept. of Pharmacol, Coll Med, Jacksonville, FL 32224, United
Researchers from Medical College Discuss Findings in Eosinophilia (BCR-JAK2 fusion in a myeloproliferative neoplasm with associated eosinophilia)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Leukocyte Diseases and Conditions - Eosinophilia. According to news reporting from Rochester, Minnesota, by NewsRx journalists, research stated, "Janus kinase 2 (JAK2) is located on chromosome 9 at band p24 and JAK2V617F is the most common mutation in Philadelphia chromosome-negative myeloproliferative neoplasms (PhMPN). However, rearrangement of JAK2 is a rare event."

The news correspondents obtained a quote from the research from Medical College, "We report a case of myeloproliferative neoplasm, unclassifiable (MPN-U) with BCR-JAK2 fusion confirmed by molecular studies. Conventional chromosome analysis (CC) revealed t (9;22)(p24;q11.2) and fluorescence in situ hybridization (FISH) showed a JAK2 gene rearrangement in 88% of interphase nuclei. The BCR-JAK2 fusion was confirmed by multiplex reverse transcriptase polymerase chain reaction (RT-PCR) and demonstrated two in-frame 5'BC/I3'JAK2 transcripts with BCR exon 1 juxtaposed to JAK2 exon 15 and exon 17, respectively. Our results, together with literature review, reveal BCR-JAK2 fusions as oncogenic genetic alterations that are associated with myeloid or lymphoid neoplasms and are frequently characterized by eosinophilia. Further, patients with BCR-JAK2 are candidates for JAK2 inhibitor therapy."

According to the news reporters, the research concluded: "Given the distinct clinical and pathological characteristics, we believe that hematological neoplasms harboring BCR-JAK2 should be included as an additional distinct entity to the current WHO category of 'myeloid and lymphoid neoplasms with eosinophilia and abnormalities of PDGFRA, PDGFRB, or FGFR', and testing for a JAK2 fusion should be pursued in neoplasms with a karyotypic 9p24 abnormality."

Our news journalists report that additional information may be obtained by

Researchers from Medical University Describe Findings in Vitamin D Deficiency (Association of vitamin D receptor gene polymorphisms and serum 25-hydroxyvitamin D levels with Crohn's disease in Chinese patients)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Nutritional and Metabolic Diseases and Conditions - Vitamin D Deficiency are presented in a new report. According to news reporting originating in Wenzhou, People's Republic of China, by NewsRx journalists, research stated, "The vitamin D receptor (VDR) regulates immune responses and inflammation through binding with 1,25-dihydroxyvitamin D, the active form of vitamin D. The serum 25-hydroxyvitamin D (25(OH)D) level clinically reflects vitamin D status in the human body."

Funders for this research include Natural Science Foundation of Zhejiang Province, Zhejiang Provincial Health Bureau.

The news reporters obtained a quote from the research from Medical University, "We investigated the association of VDR polymorphisms and 25(OH)D levels in Chinese patients with Crohn's disease (CD). Vitamin D receptor polymorphisms (FokI, BsmI, ApaI, and TaqI) were genotyped by SNaPshot. Serum 25(OH)D levels were measured by electrochemiluminescence immunoassay. A total of 297 patients with CD and 446 controls were recruited. Compared with controls, mutant alleles and genotypes of BsmI and TaqI were less prevalent in patients with CD (all p<0.05/4=0.0125). The AAC haplotype formed by BsmI, ApaI, and TaqI was also less prevalent in patients with CD (p=0.004). Furthermore, 124 patients and 188 controls were randomly selected for measurements of 25(OH)D levels. Average 25(OH)D level was lower in patients with CD than in controls (15.46 ± 8.11 vs 21.64 ± 9.45 ng/mL, p<0.001) and negatively linked to CD activity index (b=-0.829, p<0.001), platelet count (b=-0.253, p<0.001) and neutrophil percentage (b=-0.136, p=0.005) in patients with CD. The ApaI mutant genotype and vitamin D deficiency (<20 ng/mL) were independently associated with CD (p=0.009, p<0.001, respectively). In patients with CD, vitamin D deficiency interacted with FokI, ApaI, and TaqI mutant genotypes (p=0.027, p=0.024, and p=0.040, respectively). Vitamin D receptor (BsmI, ApaI, and TaqI) mutations and lower 25(OH)D levels are associated with CD in Chinese patients."

According to the news reporters, the research concluded: "Moreover, VDR (FokI, ApaI, and TaqI) mutations and vitamin D deficiency may have a combined impact on CD."

For more information on this research see: Association of vitamin D receptor gene polymorphisms and serum 25-hydroxyvitamin D levels with Crohn's disease in Chinese patients.
Researchers from Medical University Detail Findings in Apoptosis and Cell Death (Conditional knockdown of BCL2A1 reveals rate-limiting roles in BCR-dependent B-cell survival)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Life Science Research - Apoptosis and Cell Death. According to news reporting from Innsbruck, Austria, by NewsRx journalists, research stated, "Bcl2 family proteins control mitochondrial apoptosis and its members exert critical cell type and differentiation stage-specific functions, acting as barriers against autoimmunity or transformation. Anti-apoptotic Bcl2a1/Bfl1/A1 is frequently deregulated in different types of blood cancers in humans but its physiological role is poorly understood as quadruplication of the Bcl2a1 gene locus in mice hampers conventional gene targeting strategies."

The news correspondents obtained a quote from the research from Medical University, "Transgenic overexpression of A1, deletion of the A1-a paralogue or constitutive knockdown in the hematopoietic compartment of mice by RNAi suggested rate-limiting roles in lymphocyte development, granulopoiesis and mast cell activation. Here we report on the consequences of conditional knockdown of A1 protein expression using a reverse transactivator (rtTA)-driven approach that highlights a critical role for this Bcl2 family member in the maintenance of mature B-cell homeostasis. Furthermore, we define the A1/Bim (Bcl-2 interacting mediator of cell death) axis as a target of key kinases mediating B-cell receptor (BCR)-dependent survival signals, such as, spleen tyrosine kinase (Syk) and Brutons tyrosine kinase (Btk)."

According to the news reporters, the research concluded: "As such, A1 represents a putative target for the treatment of B-cell-related pathologies depending on hyperactivation of BCR-emanating survival signals and loss of A1 expression accounts, in part, for the pro-apoptotic effects of Syk-or Btk inhibitors that rely on the 'BH3-only' protein Bim for cell
killing."

Our news journalists report that additional information may be obtained by contacting M. Sochalska, Division of Developmental Immunology, Biocenter, Medical University Innsbruck, Innsbruck, Austria. Additional authors for this research include E. Ottina, S. Tuzlak, S. Herzog, M. Herold and A. Villunger.

**Genetics - Medical Genetics**

**Researchers from Medical University Detail Findings in Medical Genetics (SETD5 Loss-of-Function Mutation as a Likely Cause of a Familial Syndromic Intellectual Disability with Variable Phenotypic Expression)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Genetics - Medical Genetics have been published. According to news reporting out of Warsaw, Poland, by NewsRx editors, research stated, "Loss-of-function de novo mutations in the SETD5 gene, encoding a putative methyltransferase, are an important cause of moderate/severe intellectual disability as evidenced by the results of sequencing large patient cohorts."

Financial support for this research came from National Science Centre (NCN).

Our news journalists obtained a quote from the research from Medical University, "We present the first familial case of a SETD5 mutation contributing to a phenotype of congenital heart defects and dysmorphic features, with variable expression, in two siblings and their father. Interestingly, the father demonstrated only mild intellectual impairment."

According to the news editors, the research concluded: "Family based exome sequencing combined to careful parental phenotyping may reveal a more complex clinical picture in newly recognized syndromes."

Our news journalists report that additional information may be obtained by...
Researchers from Medical University Discuss Findings in Melanosis (Comparison of efficacy of products containing azelaic acid in melasma treatment)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Skin Diseases and Conditions - Melanosis have been presented. According to news originating from Katowice, Poland, by NewsRx correspondents, research stated, "Melasma is one of the most frequently diagnosed hyperpigmentation changes on the skin of women's faces. Nearly 30% of women using oral estrogen therapy struggle with this problem."

Financial support for this research came from Medical University of Silesia in Katowice.

Our news journalists obtained a quote from the research from Medical University, "A common way of reducing melasma is the application of azelaic acid products. Comparison of efficacy of three dermocosmetic products, containing azelaic acid, in the reduction in melasma for women aged 35-55. A group of 60 women diagnosed with melasma were divided into three even, twenty-person subgroups. Each subgroup was assigned one dermocosmetic product containing azelaic acid. For 24 weeks, the patients applied the assigned product twice a day. The level of the colorant within the hyperpigmentation was marked before the treatment, after 1 month, after 3 months, and after 6 months of therapy. The pigmentation was measured using Mexameter ® (Courage + Khazaka electronic, Germany). In addition, during each inspection, the patients' level of hydration, elasticity, and intensity of erythema was checked using Corneometer ®, Reviscometer ®. All dermocosmetics containing azelaic acid that were applied significantly contributed to the reduction in pigment in the pigmentary lesion. The largest decrease in the amount of pigment was observed in the first 3 months of use of the products. A combination containing 20% azelaic acid and mandelic acid, phytic acid, 4N-butyl resorcinol, and ferulic acid proved to be the most effective dermocosmetic III (Sesderma, Valencia, Spain). Dermocosmetics containing azelaic acid significantly contribute to the clearing of melasma."

According to the news editors, the research concluded: "The effect depends on the treatment time, the acid concentration, and addition of other components."

Researchers from Memorial Sloan-Kettering Cancer Center Detail New Studies and Findings in the Area of Multiple Myeloma (Upfront plerixafor plus G-CSF versus cyclophosphamide plus G-CSF for stem cell mobilization in multiple myeloma: efficacy ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Oncology - Multiple Myeloma have been published. According to news originating from New York City, New York, by NewsRx correspondents, research stated, "Cyclophosphamide plus G-CSF (C+G-CSF) is one of the most widely used stem cell (SC) mobilization regimens for patients with multiple myeloma (MM). Plerixafor plus G-CSF (P+G-CSF) has demonstrated superior SC mobilization efficacy when compared with G-CSF alone and has been shown to rescue patients who fail mobilization with G-CSF or C+G-CSF."

Our news journalists obtained a quote from the research from Memorial Sloan-Kettering Cancer Center, "Despite the proven efficacy of P+G-CSF in upfront SC mobilization, its use has been limited, mostly due to concerns of high price of the drug. However, a comprehensive comparison of the efficacy and cost effectiveness of SC mobilization using C+G-CSF versus P+G-CSF is not available. In this study, we compared 111 patients receiving C+G-CSF to 112 patients receiving P+G-CSF. The use of P+G-CSF was associated with a higher success rate of SC collection defined as &\#10878;5 × 10^6 CD34+ cells/kg (94 versus 83%, p=0.013) and less toxicities. Thirteen patients in the C+G-CSF arm were hospitalized owing to complications while none in the P+G-CSF group. C+G-CSF was associated with higher financial burden as assessed using institutional-specific costs and charges (p <0.001) as well as using Medicare reimbursement rates (p=0.27)."

According to the news editors, the research concluded: "Higher rate of hospitalization, increased need for salvage mobilization, and increased G-CSF use account for these differences."

For more information on this research see: Upfront plerixafor plus G-CSF versus cyclophosphamide plus G-CSF for stem cell mobilization in multiple myeloma: efficacy and cost analysis study. Bone Marrow Transplantation, 2016;51(4):546-52. Bone Marrow Transplantation can be contacted at: Nature Publishing Group, 345 Park Avenue South, New York, NY 10010-1707, USA. (Nature Publishing Group - www.nature.com/; Bone Marrow
Researchers from Memorial Sloan-Kettering Cancer Center Discuss Findings in Thyroid Cancer (Nodal metastases in thyroid cancer: prognostic implications and management)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Oncology - Thyroid Cancer are discussed in a new report. According to news reporting out of New York City, New York, by NewsRx editors, research stated, "The significance of cervical lymph node metastases in differentiated thyroid cancer has been controversial and continues to evolve. Current staging systems consider nodal metastases to confer a poorer prognosis, particularly in older patients."

Our news journalists obtained a quote from the research from Memorial Sloan-Kettering Cancer Center, "Increasingly, the literature suggests that characteristics of the metastatic lymph nodes such as size and number are also prognostic. There is a growing trend toward less aggressive treatment of low-volume nodal disease."

According to the news editors, the research concluded: "The aim of this review is to summarize the current literature and discuss prognostic and management implications of lymph node metastases in differentiated thyroid cancer."

For more information on this research see: Nodal metastases in thyroid cancer: prognostic implications and management. Future Oncology, 2016;12(7):981-94.

Our news journalists report that additional information may be obtained by contacting L.Y. Wang, Dept. of Surgery, Head & Neck Service, Memorial Sloan-Kettering Cancer Center, 1275 York Avenue, New York, NY 10065, United States.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.2217/fon.16.10. This DOI is a link to an online electronic document that is either free or for purchase.
Researchers from Memorial Sloan-Kettering Cancer Center Report Findings in Mucositis (Role of Gabapentin in Managing Mucositis Pain in Patients Undergoing Radiation Therapy to the Head and Neck)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Digestive System Diseases and Conditions - Mucositis is now available. According to news reporting originating in New York City, New York, by NewsRx journalists, research stated, "Oral mucositis (OM) is a painful and debilitating side effect that affects 80%-100% of patients undergoing radiation therapy for head and neck cancer. This dose-limiting side effect may potentially lead to pain, dehydration, malnutrition, infection, and treatment breaks."

The news reporters obtained a quote from the research from Memorial Sloan-Kettering Cancer Center, "Treatment breaks can lead to decreased disease control and suboptimal patient outcomes. No primary prevention exists for OM, and management is focused on pain control. Compelling evidence exists that OM pain has somatic and neuropathic components. This article reviews the existing literature on the use of gabapentin (Neurontin®) as a co-analgesic in treating the neuropathic pain in OM. A literature search was performed using CINAHL® and PubMed with the search terms gabapentin and oral mucositis. The selected articles were briefly screened for relevance, and three were included in this review. No systematic reviews exist on the role of gabapentin for neuropathic pain in radiation-induced OM. Two retrospective studies concluded that gabapentin reduced escalation of opioid doses and unplanned treatment breaks. One retrospective study demonstrated favorable swallowing outcomes."

According to the news reporters, the research concluded: "Pain and OM are nursing-sensitive outcomes that can be significantly affected by evidence-based nursing interventions."

For more information on this research see: Role of Gabapentin in Managing Mucositis Pain in Patients Undergoing Radiation Therapy to the Head and Neck. *Clinical Journal of Oncology Nursing*, 2016;20(6):623-628. *Clinical Journal of Oncology Nursing* can be contacted at: Oncology Nursing Soc, 125 Enterprise Dr, Pittsburgh, PA 15275, USA.

Our news correspondents report that additional information may be obtained by contacting C.A. Milazzo-Kiedaisch, Mem Sloan Kettering Canc Center, New York, NY 10021, United States. Additional authors for this research include J. Itano and P.R. Dutta.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1188/16.CJON.623-628. This DOI is a link to an online electronic document that is either free or for purchase.

Researchers from Memorial Sloan-Kettering Cancer Center Report Findings in Vascular Malformations (Vascular malformation with phleboliths involving the parotid gland: A case report with a review of the literature)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Cardiovascular Diseases and Conditions - Vascular Malformations is the subject of a report. According to news reporting originating from New York City, New York, by NewsRx correspondents, research stated, "Phleboliths within the parotid gland are exceedingly rare. We report a case of a venous malformation with multiple phleboliths that involved the left parotid gland and extended into the extraparotid tissue in a 43-year-old woman."

Our news editors obtained a quote from the research from Memorial Sloan-Kettering Cancer Center, "We also review 13 similar cases that have been reported since 1948, and we highlight the significance of distinguishing phleboliths from sialoliths because management of the two can be entirely different. Phleboliths in and around the salivary glands primarily affect the parotid and submandibular glands in adult women. Patients can present with recurrent, intermittent swelling that may be associated with food intake and hyposalivation."

According to the news editors, the research concluded: "Any sialolithiasis located outside of its most common location in the submandibular glands must be investigated thoroughly before surgery."

For more information on this research see: Vascular malformation with phleboliths involving the parotid gland: A case report with a review of the literature. Ear, Nose, & Throat Journal, 2015;94(10-11):E1-5.

The news editors report that additional information may be obtained by contacting C. Ho, Dept. of Pathology, Memorial Sloan Kettering Cancer Center, New York, NY, United States. Additional authors for this research include B.L. Judson and M.L Prasad.

Keywords for this news article include: New York City, United States, Article Review, Vascular Malformations, Congenital Abnormalities, North and Central America, Cardiovascular Abnormalities, Cardiovascular Diseases and Conditions.

Researchers from Metabolic and Atherosclerosis Research Center Report on Findings in Hypercholesterolemia (What role will proprotein convertase subtilisin/kexin type 9 inhibitors play in hyperlipidemia management?)

Nutritional and Metablic Diseases and Conditions - ...
2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Nutritional and Metabolic Diseases and Conditions - Hypercholesterolemia. According to news reporting originating from Cincinnati, Ohio, by NewsRx editors, the research stated, "This article summarizes the role that the recently approved proprotein convertase subtilisin/kexin type 9 (PCSK9) monoclonal antibodies (mAbs) will play in LDL cholesterol management. The discovery of PCSK9 in 2003 and its association with a rare form of autosomal-dominant hypercholesterolemia quickly led to the understanding of the role of circulating PCSK9 in regulating the recycling of the LDL receptor and LDL cholesterol (LDL-C) and impact on cardiovascular disease."

Our news editors obtained a quote from the research from Metabolic and Atherosclerosis Research Center, "Development of monoclonal antibodies that bind and inhibit PCSK9 entered clinical development in late 2009 and demonstrated substantial LDL-C reductions as monotherapy, added to statins, in heterozygous familial hypercholesterolemia and patients intolerant of statins. Large and comprehensive trials over the last 5 years also indicated good tolerability and safety and resulted in the 2015 regulatory approval in the USA and Europe for the marketing of two mAbs, evolocumab and alirocumab, for the treatment of LDL-C."

According to the news editors, the research concluded: "The background, clinical trials and approved indications for the current PCSK9 inhibitors are reviewed along with their likely role in the management of LDL-C and cardiovascular disease prevention."

For more information on this research see: What role will proprotein convertase subtilisin/kexin type 9 inhibitors play in hyperlipidemia management? Current Opinion In Endocrinology, Diabetes, and Obesity, 2016;23(2):97-105.

The news editors report that additional information may be obtained by contacting E.A. Stein, Metabolic and Atherosclerosis Research Center, Cincinnati, Ohio, United States.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1097/MED.0000000000000242. This DOI is a link to an online electronic document that is either free or for purchase.

Cardiology

Researchers from Midwestern University Report Details of New Studies and Findings in the Area of Cardiology (Sex-Dependent Effects of Dietary Genistein on Echocardiographic Profile and Cardiac GLUT4 Signaling in Mice)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Cardiology have been published. According to news reporting out of Glendale, Arizona, by NewsRx editors, research stated, "This study aimed to determine whether genistein diet resulted in changes in cardiac function, using echocardiography, and expression of key proteins involved in glucose uptake by the myocardium. Intact male and female C57BL/6J mice (aged 4-6 weeks) were fed either 600
mg genistein/kg diet (600 G) or 0 mg genistein/kg diet (0G) for 4 weeks."

Our news journalists obtained a quote from the research from Midwestern University, "Echocardiography data revealed sex-dependent differences in the absence of genistein: compared to females, hearts from males exhibited increased systolic left ventricle internal dimension (LVIDs), producing a decrease in function, expressed as fractional shortening (FS). Genistein diet also induced echocardiographic changes in function: in female hearts, 600G induced a 1.5-fold (P < 0.05) increase in LVIDs, resulting in a significant decrease in FS and whole heart surface area when compared to controls (fed 0G). Genistein diet increased cardiac GLUT4 protein expression in both males (1.5-fold, P< 0.05) and females (1.76-fold, P < 0.05). However, no effects on the expression of notable intracellular signaling glucose uptake-regulated proteins were observed."

According to the news editors, the research concluded: "Our data indicate that consumption of genistein diet for 4 weeks induces echocardiographic changes in indices of systolic function in females and has beneficial effects on cardiac GLUT4 protein expression in both males and females."

For more information on this research see: Sex-Dependent Effects of Dietary Genistein on Echocardiographic Profile and Cardiac GLUT4 Signaling in Mice. Evidence-Based Complementary and Alternative Medicine, 2016();1-10. Brachytherapy

Researchers from Misericordia Hospital Discuss Findings in Brachytherapy (Recurrences and toxicity after adjuvant vaginal brachytherapy in Stage I-II endometrial cancer: A monoinstitutional experience)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Brachytherapy is the subject of a report. According to news reporting originating in Perugia, Italy, by NewsRx journalists, research stated, "To evaluate the incidences of vaginal recurrence and toxicity after vaginal brachytherapy in Stage I-II endometrial cancer. Between 2003 and 2012, 150 high-intermediate-risk Stage I and 7 Stage II
patients, median age 64 years, underwent surgery, with or without lymphadenectomy, and 3D brachytherapy: 7 Gy, at 5 mm depth from applicator surface, for 3-week fractions."

The news reporters obtained a quote from the research from Misericordia Hospital, "The effects of age, grading, number of excised lymph nodes and pathologic stage on loco-regional relapse (LRR), metastases, and tumor-related death were investigated. Vaginal toxicity was evaluated during followup visits. At 83 months of median followup, 144 patients were disease free, 2 in relapse, 7 deceased from disease, and 4 from other causes. One vaginal (0.6%), five nodal (3.2%), three pelvic over the vaginal cuff (1.9%), and one distant recurrences were seen (0.6%). The 5-year probability of LRR-free, distant metastasis-free and cause-specific survivals for all patients were 93.6% (95% confidence interval [CI]: 88.1-96.7), 97.8% (95% CI: 93.2-99.3), and 96.5% (95% CI: 93.5-99.5) and for Stage I 95.7% (95% CI: 92.2-9.1), 99.3% (95% CI: 98.0-100), and 97.7% (95% CI: 95.2-100), respectively. At multivariate analysis, Stage II disease and more than 12 lymph nodes sampled were associated with LRR (hazard ratio [HR]: 3.88; 95% CI: 1.390-10.878; p = 0.010 and HR: 6.952; 95% CI: 1.591-30.385; p = 0.010) and Stage II with metastasis and tumor-related death (HR: 23.057; 95% CI: 2.296-231.485; p = 0.008 and HR: 4.324; 95% CI: 1.223-15.290; p = 0.023). Vaginal acute and chronic toxicity was 16% and 55.4%, respectively, all only Grades 1-2. For high-to-intermediate-risk Stage I endometrial cancer, 3D vaginal brachytherapy achieved good local control and low toxicity."

According to the news reporters, the research concluded: "In Stage II, patients brachytherapy could be administered after complete surgical staging."

Our news correspondents report that additional information may be obtained by contacting E. Perrucci, Santa Maria Misericordia Hosp, Dept. of Oncohematogastroenterol Sci, Radiat Oncol Sect, Perugia, Italy. Additional authors for this research include V. Lancellotta, V. Bini, C. Zucchetti, C. Mariucci, G. Montesi, S. Saccia, I. Palumbo and C. Aristei.

Central Nervous System

Researchers from Missouri State University Report Recent Findings in Central Nervous System (Elevated Levels Of Calcitonin Gene-related Peptide In Upper Spinal Cord Promotes Sensitization Of Primary Trigeminal Nociceptive Neurons)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Central Nervous System. According to news reporting originating in Springfield, Missouri, by NewsRx journalists, research stated, "Orofacial pain conditions including temporomandibular disorder (TMD) and migraine are characterized by peripheral and central sensitization of trigeminal nociceptive neurons. The goal of this study was to investigate the role of calcitonin gene-related peptide (CGRP) in promoting..."
bidirectional signaling within the trigeminal system to mediate sensitization of primary nociceptive neurons."

Financial support for this research came from National Institutes of Health.

The news reporters obtained a quote from the research from Missouri State University, "Adult male Sprague-Dawley rats were injected intercisternally with CGRP or co-injected with the receptor antagonist CGRP(8-37) or KT 5720, a protein kinase A (PKA) inhibitor. Nocifensive head withdrawal response to mechanical stimulation was investigated using von Frey filaments. Expression of PKA, glial fibrillary acidic protein (GFAP), and ionized calcium-binding adapter molecule 1 (Iba1) in the spinal cord and phosphorylated extracellular signal-regulated kinase (P-ERK) in the ganglion was studied using immunohistochemistry. Some animals were co-injected with CGRP and Fast Blue dye and the ganglion was imaged using fluorescent microscopy. CGRP increased nocifensive responses to mechanical stimulation when compared to control. Co-injection of CGRP(8-37) or KT 5720 with CGRP inhibited the nocifensive response. CGRP stimulated PKA and GFAP expression in the spinal cord, and PERK in ganglion neurons. Seven days post injection, Fast Blue was observed in ganglion neurons and satellite glial cells. Our results demonstrate that elevated levels of CGRP in the upper spinal cord promote sensitization of primary nociceptive neurons via a mechanism that involves activation of PKA centrally and P-ERK in ganglion neurons."

According to the news reporters, the research concluded: "Our findings provide evidence of bidirectional signaling within the trigeminal system that facilitate increased neuron-glial communication within the ganglion associated with trigeminal sensitization."

Our news correspondents report that additional information may be obtained by contacting P.L. Durham, Missouri State Univ, Center Biomed & Life Sci, Springfield, MO 65897, United States. Additional authors for this research include J.L. Hawkins and P.L. Durham.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1016/j.neuroscience.2016.10.013. This DOI is a link to an online electronic document that is either free or for purchase.

Inhibition

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Oncology - Prostate Cancer. According to news originating from Boston, Massachusetts, by NewsRx correspondents, research stated, "The bone-conserved metastatic phenotype of prostate cancer is a prototype of nonrandom metastatic behavior. Adhesion of prostate cancer cells to fibronectin via the integrin a5 (ITGA5) has been proposed as a candidate bone marrow niche localization mechanism."

Our news journalists obtained a quote from the research from Molecular Oncology Research Institute, "We hypothesized that the mechanisms whereby ITGA5 regulates the adhesion-mediated survival of prostate cancer cells will define novel therapeutic approaches. ITGA5 shRNA reduced expression of BCL-2 family members and induced apoptosis in PC-3 cells. In these PTEN-mutant cells, pharmacologic inhibition of the PI3K signaling pathway in combination with ITGA5 knockdown enhanced apoptosis. Chemical parsing studies with BH3 mimetics indicated that PI3K/Akt inhibition in combination with BCL-XL-specific inhibition induces synergistic apoptosis specifically in PTEN-mutant prostate cancer cells, whereas single-agent PI3K/Akt inhibitors did not. Given the importance of PTEN loss in the progression of prostate and other cancers, synthetic lethality induced by combinatorial PI3K/Akt and BCL-XL inhibition represents a valuable therapeutic strategy. Synthetic lethality in PTEN-mutant prostate cancer cells with combined PI3K/Akt and BCL-XL inhibition. PTENmutant prostate cancer cells expressing ITGA5 bind to fibronectin in the putative bone marrow niche and transduce survival signals to BCL-XL."

According to the news editors, the research concluded: "Additional PTEN-regulated signals independent of the PI3K/Akt pathway likely feed into the BCL-XL-regulated survival program to explain synthetic lethality observed with the combination."

For more information on this research see: Synthetic Lethality in PTEN-Mutant Prostate Cancer Is Induced by Combinatorial PI3K/Akt and BCL-XL Inhibition. Molecular Cancer Research, 2016;14(12):1176-1181. Molecular Cancer Research can be contacted at: Amer Assoc Cancer Research, 615 Chestnut St, 17TH Floor, Philadelphia, PA 19106-4404, USA. Viral RNA

Researchers from Montana State University Report Findings in Viral RNA (Programmed Self-Assembly of an Active P22-Cas9 Nanocarrier System)
2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Viral RNA have been presented. According to news reporting originating from Bozeman, Montana, by NewsRx correspondents, research stated, "Clustered Regularly Interspaced Short Palindromic Repeats (CRISPR) RNA-guided endonucleases are powerful new tools for targeted genome engineering. These nucleases provide an efficient and precise method for manipulating eukaryotic genomes; however, delivery of these reagents to specific cell-types remains challenging."

Funders for this research include MJ Murdock Charitable Trust, American Heart Association, Office of Experimental Program to Stimulate Competitive Research, Amgen, National Institute of General Medical Sciences, National Science Foundation.

Our news editors obtained a quote from the research from Montana State University, "Virus-like particles (VLPs) derived from bacteriophage P22, are robust supramolecular protein cage structures with demonstrated utility for cell type-specific delivery of encapsulated cargos. Here, we genetically fuse Cas9 to a truncated form of the P22 scaffold protein, which acts as a template for capsid assembly as well as a specific encapsulation signal for Cas9. Our results indicate that Cas9 and a single-guide RNA are packaged inside the P22 VLP, and activity assays indicate that this RNA-guided endonuclease is functional for sequence-specific cleavage of dsDNA targets."

According to the news editors, the research concluded: "This work demonstrates the potential for developing P22 as a delivery vehicle for cell specific targeting of Cas9."

For more information on this research see: Programmed Self-Assembly of an Active P22-Cas9 Nanocarrier System. Molecular Pharmaceutics, 2016;13(3):1191-6. (American Chemical Society - www.acs.org; Molecular Pharmaceutics - www.pubs.acs.org/journal/mpohbp)

The news editors report that additional information may be obtained by contacting S. Qazi, Dept. of Microbiology and Immunology, Montana State University, Bozeman, Montana 59717, United States. Additional authors for this research include H.M. Miettinen, R.A. Wilkinson, K. McCoy, T. Douglas and B. Wiedenheit.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1021/acs.molpharmaceut.5b00822. This DOI is a link to an online electronic document that is either free or for purchase.

Heart Disorders and Diseases - Heart Disease

Researchers from Morristown Medical Center Report Recent Findings in Heart Disease (Bleeding Events Before Coronary Angiography in Patients With Non-ST-Segment Elevation Acute Coronary Syndrome)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Heart Disorders and Diseases - Heart Disease. According to news reporting from Morristown, New Jersey, by NewsRx journalists, research stated, "Upstream administration of antithrombotic drugs to patients with non-ST-segment elevation acute coronary syndromes before coronary angiography is a common practice
despite an incomplete understanding of the risks and benefits. The authors analyzed the incidence of bleeding and ischemic events occurring before angiography and assessed their association with antithrombotic drugs and mortality risk."

The news correspondents obtained a quote from the research from Morristown Medical Center, "All patients from the ACUITY (Acute Catheterization and Urgent Intervention Triage Strategy) trial with planned angiography after enrollment were included. Bleeding events were classified according to the ACUITY scale as major or nonmajor bleeding. Kaplan-Meier and Cox proportional hazards analyses were performed. Of 13,726 patients, 275 (2.0%) bled before angiography, including 52 (0.4%) with major bleeding. Forty-four (0.3%) experienced myocardial infarction. The median time from randomization to coronary angiography was 4.5 h (interquartile ratio [IQR]: 1.7 to 19.7 h) for patients who did not bleed while waiting for angiography and 27.9 h (IQR: 21.9 to 65.6 h) for patients who bled while waiting for angiography (p < 0.001). Bleeding events accrued linearly over time, reaching 10.4% at 96 h post-randomization. Independent predictors of bleeding before angiography included age (adjusted hazard ratio [HR]: 1.03 per year of age; 95% confidence interval [CI]: 1.01 to 1.04; p < 0.001), renal insufficiency (adjusted HR: 1.48; 95% CI: 1.07 to 2.04; p = 0.02), and use of multiple antithrombotic drugs (adjusted HR: 1.33; 95% CI: 1.14 to 1.56; p< 0.001). Bleeding before coronary angiography was associated with longer hospitalization (4.8 days [IQR: 3.0 to 8.9 days] vs. 3.0 days [IQR: 1.9 to 5.9 days]; p < 0.001). Patients who bled before angiography were more likely to die within 1 year than patients who did not bleed (8.5% vs. 4.1%; p< 0.001; adjusted HR: 1.89 (95% CI: 1.23 to 2.90; p = 0.004). Upstream antithrombotic treatment of patients with non-ST-segment elevation acute coronary syndromes awaiting coronary angiography is associated with excess bleeding with mortality implications."

According to the news reporters, the research concluded: "Bleeding avoidance strategies before angiogram, including early angiography, may negate the need to prolong upstream antithrombotic treatment and improve the overall risk-benefit balance for these patients."

Our news journalists report that additional information may be obtained by contacting P. Genereux, Morristown Med Center, Morristown, NJ, United States. Additional authors for this research include A.J. Kirtane, S.J. Pocock, G.M. Ayele, E.N. Deliargyris, R. Mehran, G.W. Stone and P. Genereux.

Researchers from Mukogawa Women's University Describe Findings in Hydro-Lyases (Reduced Production of Hydrogen Sulfide and Sulfane Sulfur Due to Low Cystathionine beta-Synthase Levels in Brain Astrocytes of Stroke-Prone Spontaneously ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Enzymes and Coenzymes - Hydro-Lyases. According to news reporting out of Nishinomiya, Japan, by NewsRx editors, research stated, "Stroke-prone spontaneously hypertensive rats (SHRSP/Izm; SHRSP) develop severe hypertension and die of cerebral stroke. However, the genetic mechanisms underlying their stroke susceptibility have not been clarified yet."

Our news journalists obtained a quote from the research from Mukogawa Women's University, "In this study, we used astrocytes from the newborn brain cortex of spontaneously hypertensive rats (SHR/Izm; SHR) and SHRSP to find the difference of genetic characteristics. Astrocytes are known to have functions of vasodilation and nutrient uptake for neurons in the brain. The continuous generation of hydrogen peroxide (H2O2) dose-dependently causes cell death in astrocytes, and SHRSP was more vulnerable than SHR. We found that the total thiols decreased in SHRSP astrocytes but the total glutathione (GSH) did not change. Hydrogen sulfide (H2S), which is known to protect cells through anti-oxidant and vasodilatory effects, is produced by cystathionine beta-synthase (CBS) in astrocytes. We found that H2S production was significantly decreased in SHRSP as compared to SHR. This was caused by the decreasing expression of mRNA, protein and enzyme activity of CBS in astrocytes. We also found that astrocyte cell death from oxidative stress could be prevented by GYY4137 H2S donor. H2S is also known to cause protein S-sulfhydration to modify enzyme activity. Sulfane sulfur in astrocytes was significantly lower in SHRSP and decreased by CBS inhibitor."

According to the news editors, the research concluded: "We showed that astrocytes in SHRSP vulnerable to oxidative stress may be caused by reduction of H2S through lower expression and activity of CBS."

Our news journalists report that additional information may be obtained by contacting S. Juman, Mukogawa Womens Univ, Sch Pharm & Pharmacut Sci, Nishinomiya, Hyogo 6638179, Japan. Additional authors for this research include Y. Nara, N. Yasui, H. Negishi, H. Okuda, N. Takado and T. Miki.

Keywords for this news article include: Nishinomiya, Japan, Asia, Cystathionine beta-Synthase, Dicarboxylic Amino Acids, Enzymes and Coenzymes, Noncarboxylic Acids, Diamino Amino Acids, Inorganic Chemicals, Sulfur Amino Acids, Hydrogen Sulfide, Sulfur Compounds, Hydro-Lyases, Chalcogens, Astrocytes, Neuroglia, Elements, Genetics, Stroke, Gases, Mukogawa Women's University.

Researchers from NHS Foundation Trust Discuss Findings in Arteriovenous Malformation (Novel use of 4D-CTA in imaging of intranidal aneurysms in an acutely ruptured arteriovenous malformation: is this the way forward?)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Arteriovenous Malformation have been published. According to news reporting out of Liverpool, United Kingdom, by NewsRx editors, research stated, "Ruptured arteriovenous malformation (AVM) is a frequent cause of intracranial hemorrhage. The presence of associated aneurysms, especially intranidal aneurysms, is considered to increase the risk of re-hemorrhage."

Our news journalists obtained a quote from the research from NHS Foundation Trust, "We present two cases where an intranidal aneurysm was demonstrated on four-dimensional CT angiography (time-resolved CT angiography) (4D-CTA). These features were confirmed by digital subtraction angiography (catheter arterial angiogram)."

According to the news editors, the research concluded: "This is the first report of an intranidal aneurysm demonstrated by 4D-CTA. 4D-CTA can offer a comprehensive evaluation of the angioarchitecture and flow dynamics of an AVM for appropriate classification and management."

Our news journalists report that additional information may be obtained by contacting A. Chandran, Walton Center NHS Fdn Trust, Dept. of Neuroradiol, Liverpool L9 7LJ, Merseyside, United Kingdom. Additional authors for this research include M. Radon, S. Biswas, K. Das, M. Puthuran and H. Nahser.

Keywords for this news article include: Liverpool, United Kingdom, Europe, Cardiovascular Diseases and Conditions, Cardiovascular Abnormalities, Arteriovenous Malformations, Congenital Abnormalities, Vascular Malformations, Cardiology, Angiography, Hemorrhage, Aneurysm, NHS Foundation Trust.

Connective Tissue Cells

Researchers from Nagoya City University Report New Studies and Findings in the Area of Connective Tissue Cells [A New Splice Variant of Large Conductance Ca2+-activated K+ (BK) Channel Subunit Alters Human Chondrocyte Function]
2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Connective Tissue Cells. According to news reporting from Nagoya, Japan, by NewsRx journalists, research stated, "Large conductance Ca2+-activated K+ (BK) channels play essential roles in both excitable and non-excitabile cells. For example, in chondrocytes, agonist-induced Ca2+ release from intracellular store activates BK channels, and this hyperpolarizes these cells, augments Ca2+ entry, and forms a positive feedback mechanism for Ca2+ signaling and stimulation-secretion coupling."

The news correspondents obtained a quote from the research from Nagoya City University, "In the present study, functional roles of a newly identified splice variant in the BK channel subunit (BKe2) were examined in a human chondrocyte cell line, OUMS-27, and in a HEK293 expression system. Although BKe2 lacks exon2, which codes the intracellular S0-S1 linker (Glu-127-Leu-180), significant expression was detected in several tissues from humans and mice. Molecular image analyses revealed that BKe2 channels are not expressed on plasma membrane but can traffic to the plasma membrane after forming hetero-tetramer units with wild-type BK (BKWT). Single-channel current analyses demonstrated that BK hetero-tetramers containing one, two, or three BKe2 subunits are functional. These hetero-tetramers have a smaller single channel conductance and exhibit lower trafficking efficiency than BKWT homotetramers in a stoichiometry-dependent manner. Site-directed mutagenesis of residues in exon2 identified Helix2 and the linker to S1 (Trp-158-Leu-180, particularly Arg-178) as an essential segment for channel function including voltage dependence and trafficking. BKe2 knockdown in OUMS-27 chondrocytes increased BK current density and augmented the responsiveness to histamine assayed as cyclooxygenase-2 gene expression."

According to the news reporters, the research concluded: "These findings provide significant new evidence that BKe2 can modulate cellular responses to physiological stimuli in human chondrocyte and contribute under pathophysiological conditions, such as osteoarthritis."

Our news journalists report that additional information may be obtained by contacting Y. Imaizumi, Nagoya City University, Grad Sch Pharmaceut Sci, Dept. of Mol & Cellular Pharmacol, Mizuho Ku, Nagoya, Aichi 4678603, Japan. Additional authors for this research include S. Ohya, H. Yamamura, W.R. Giles and Y. Imaizumi.

Keywords for this news article include: Nagoya, Japan, Asia, Connective Tissue Cells, Chondrocytes, Genetics, Nagoya City University.

**Reproductive Medicine - Male Infertility**

**Researchers from Nanjing Medical University Report Details of New Studies and Findings in the Area of Male Infertility (Common SNP in hsa-miR-196a-2 increases hsa-miR-196a-5p expression and predisposes to idiopathic male infertility in Chinese ...)**
2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Reproductive Medicine - Male Infertility. According to news reporting from Nanjing, People's Republic of China, by NewsRx journalists, research stated, "MicroRNA plays an important role in spermatogenesis. Whether pre-miRNAs polymorphisms are associated with idiopathic male infertility remains obscure."

The news correspondents obtained a quote from the research from Nanjing Medical University. "In this study, 1378 idiopathic infertile males and 486 fertile controls were included between 2006 and 2014. Genotype of three polymorphisms (hsa-mir-146a rs2910164, hsa-mir-196a-2 rs11614913, and hsa-mir-499 rs3746444) and expression of miRNA in seminal plasma were examined by TaqMan method. The role of hsa-miR-196a-5p in cell proliferation, apoptosis and cell cycle were also examined in GC-2 cells. Our results demonstrated that rs11614913 of hsa-miR-196a-2 was significantly associated with idiopathic infertility (TT vs. CT: p=0.014; TT vs. CC: p=0.005; TT vs. CT + CC: p=0.003). In following stratified analysis, we found that rs11614913 exhibited a significantly higher risk of asthenospermia, oligozoospermia and azoospermia. However, no significant association was observed between the other two polymorphisms and idiopathic male infertility risk. In a genotype-expression correlation analysis, rs11614913 CC was significantly associated with elevated expression of hsa-miR-196a-5p (p <0.05). Additionally, apoptosis levels were significantly increased in hsa-miR-196a-5p mimic treated GC-2 cells, while decreased in hsa-miR-196a-5p inhibitor treated GC-2 cells."

According to the news reporters, the research concluded: "Our data revealed a significant relationship between hsa-miR-196a-2 polymorphism and idiopathic male infertility."

For more information on this research see: Common SNP in hsa-miR-196a-2 polymorphism and idiopathic male infertility. In a genotype-expression correlation analysis, rs11614913 CC was significantly associated with elevated expression of hsa-miR-196a-5p (p <0.05). Additionally, apoptosis levels were significantly increased in hsa-miR-196a-5p mimic treated GC-2 cells, while decreased in hsa-miR-196a-5p inhibitor treated GC-2 cells."

According to the news reporters, the research concluded: "Our data revealed a significant relationship between hsa-miR-196a-2 polymorphism and idiopathic male infertility.

For more information on this research see: Common SNP in hsa-miR-196a-2 polymorphism and idiopathic male infertility. Scientific Reports, 2016;6():19825. (Nature Publishing Group - www.nature.com/; Scientific Reports - www.nature.com/srep/)

Oncology - Cancer Risk

Researchers from Nanjing Medical University Report Recent Findings in Cancer Risk (CXC motif chemokine receptor 4 gene polymorphism and cancer risk)
2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Oncology - Cancer Risk is the subject of a report. According to news reporting from Jiangsu, People's Republic of China, by NewsRx journalists, research stated, "Previous epidemiological studies have reported the relationship between CXC motif chemokine receptor 4 (CXCR4) synonymous polymorphism (rs2228014), and risk of cancer, but the results remained conflicting and controversial. Therefore, this study was devised to evaluate the genetic effects of the rs2228014 polymorphism on cancer risk in a large meta-analysis."

The news correspondents obtained a quote from the research from Nanjing Medical University, "The computer-based databases (EMBASE, Web of Science, and PubMed) were searched for all relevant studies evaluating rs2228014 and susceptibility to cancer. In the analysis, pooled odds ratios (ORs) with its corresponding 95% confidence intervals (CIs) were calculated in 5 genetic models to assess the genetic risk. Egger regression and Begg funnel plots test were conducted to appraise the publication bias. Data on rs2228014 polymorphism and overall cancer risk were available for 3684 cancer patients and 5114 healthy controls participating in 11 studies. Overall, a significantly increased risk of cancer was associated with rs2228014 polymorphism in homozygote model (OR=2.01, 95% CI: 1.22-3.33) and in recessive model (OR=1.97, 95% CI: 1.23-3.16). When stratified by ethnicity, the results were positive only in Asian populations (homozygote model: OR=1.36, 95% CI: 1.13-1.65; homozygote model: OR=2.43, 95% CI: 1.21-4.91; dominant model: OR=1.47, 95% CI: 1.13-1.90; recessive model: OR=2.25, 95% CI: 1.13-4.48; and allele model: OR=1.48, 95% CI: 1.10-1.99). Besides, in the subgroup analysis by source of control, the result was significant only in population-based control (homozygote model: OR=2.39, 95% CI: 1.06-5.40; recessive model: pooled OR=2.24, 95% CI: 1.02-4.96). In general, our results first indicated that the rs2228014 polymorphism in CXCR4 gene is correlated with an increased risk of cancer, especially among Asian ethnicity."

According to the news reporters, the research concluded: "Large, well-designed epidemiological studies are required to verify the current findings."

For more information on this research see: CXC motif chemokine receptor 4 gene polymorphism and cancer risk. Medicine, 2016;95(49):65-70. Medicine can be contacted at: Lippincott Williams & Wilkins, Two Commerce Sq, 2001 Market St, Philadelphia, PA 19103, USA. Researchers from Nanjing Medical University Report Recent Findings in Clopidogrel Therapy (Interleukin-10 does not modulate clopidogrel platelet response in mice)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Drugs and Therapies - Clopidogrel Therapy have been published. According to news originating from Jiangsu, People's Republic of China, by NewsRx correspondents, research stated, "ESSENTIALS: It is unclear whether interleukin-10 (IL-10) could affect clopidogrel metabolism and response. The bioactivation of and response to clopidogrel were determined between mice with or without IL-10."

Funders for this research include National Natural Science Foundation of China, Department of Science and Technology of the Province of Jiangsu, Natural Science Foundation of the Province of Jiangsu, Nanjing First Hospital, China, Ministry of Human Resource and Social Security of China.

Our news journalists obtained a quote from the research from Nanjing Medical University, "Maximum clopidogrel active metabolite levels were the major driver of platelet response to clopidogrel. IL-10 did not modulate maximum levels of clopidogrel active metabolite and its antiplatelet effects. Elevated plasma interleukin-10 (IL-10) levels were observed in patients who responded less to clopidogrel (a prodrug that is required for further metabolic bioactivation in the liver). However, no data are currently available suggesting whether there is such an association. To systematically explore possible differences in the formation of and response to clopidogrel active metabolite (CAM) in mice with or without IL-10 gene expression. A single oral dose of clopidogrel (10 mg kg(-1)) was given to IL-10 knockout (KO) mice and wild-type (WT) control mice, respectively, and pharmacokinetic parameters of clopidogrel and CAM were calculated. Moreover, adenosine diphosphate-induced whole-blood platelet aggregation was measured in mice receiving 0, 5, 10, or 20 mg kg(-1) of clopidogrel, respectively. Compared with IL-10 KO mice, WT mice had significantly lower area under the plasma concentration-time curve (AUC) of CAM as a result of a shorter mean elimination half-life but had significantly higher AUC of clopidogrel due to slower systemic clearance and smaller volume of distribution. Although AUC of CAM was significantly lower in WT mice than in KO mice, antiplatelet effects of clopidogrel did not differ significantly between the two mouse groups, as their maximum plasma concentrations (Cmax) of CAM were not significantly different."

According to the news editors, the research concluded: "IL-10 expression level affects AUC rather than Cmax of CAM, but the Cmax of CAM is the major driver of antiplatelet effects of clopidogrel in mice."

The news correspondents report that additional information may be obtained from Q. Yin, General Clinical Research Center, Nanjing First Hospital, Nanjing Medical University, Nanjing, Jiangsu, People's Republic of China. Additional authors for this research include T. Tai, J.Z. Ji, Q.Y. Mi, M.R. Zhang, W.J. Huang, C.C. Cao and H.G Xie.

Researchers from Nanjing Medical University Report Recent Findings in Lung Cancer (Adverse events risk associated with anti-VEGFR agents in the treatment of advanced nonsmall-cell lung cancer A meta-analysis)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Oncology - Lung Cancer. According to news reporting from Jiangsu, People's Republic of China, by NewsRx journalists, research stated, "To perform this meta-analysis, we investigated the risk of the most clinically relevant adverse events related to antivascular endothelial growth factor receptor (VEGFR) agents in advanced nonsmall-cell lung cancer (NSCLC). A comprehensive literature search for studies published up to October 2015 was performed."

The news correspondents obtained a quote from the research from Nanjing Medical University, "Prospective randomized controlled phase II/III clinical trials that comparing therapy with or without anti-VEGFR agents for advanced NSCLC were included for analysis. Summary relative risk (RR) and 95% confidence intervals (CIs) were calculated using random effects or fixed effects according to the heterogeneity among included trials. A total of 11,701 patients from 18 clinical trials were included for analysis. Pooled RR showed that the use of anti-VEGFR agents significantly increased the risk of developing hypertension (RR 4.71, 95% CI 3.29-6.73, P < 0.001) and fatal adverse events (RR 1.33, 95% CI 1.12-1.58, P = 0.001). No statistically significant differences were found for gastrointestinal (GI) perforation (P = 0.41), arterial or venous thromboembolic events (P = 0.49 and P = 0.16, respectively), or hemorrhagic events (P = 0.81). Sensitive analysis indicated that the significance estimate of pooled RR of fatal adverse event (FAEs) was not significantly influenced by omitting any single study."

According to the news reporters, the research concluded: "The use of anti-VEGFR agents in advanced NSCLC does significantly increase the risk of hypertension and fatal adverse events, but not for arterial or venous thromboembolic events, GI perforation, or hemorrhagic events."

For more information on this research see: Adverse events risk associated with anti-VEGFR agents in the treatment of advanced nonsmall-cell lung cancer A meta-analysis. Medicine, 2016;95(48):15-21. Medicine can be contacted at: Lippincott Williams & Wilkins, Two Commerce Sq, 2001 Market St, Philadelphia, PA 19103, USA. Researchers from Nanjing University Discuss Findings in Non-Small Cell Lung Cancer (Inhibition of autophagy by andrographolide resensitizes cisplatin-resistant non-small cell lung carcinoma cells via activation of the Akt/mTOR pathway)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Oncology - Non-Small Cell Lung Cancer are presented in a new report. According to news reporting out of Jiangsu, People's Republic of China, by NewsRx editors, research stated, "Resistance to cisplatin is a major obstacle for the success of non-small cell lung cancer therapy. The mechanisms underlying cisplatin resistance are not fully understood."

Funders for this research include National Natural Science Foundation of China, Natural Science Foundation of Jiangsu Province.

Our news journalists obtained a quote from the research from Nanjing University, "In this study, we found that the increase of basal autophagy accompanied the development of cisplatin resistance. Meanwhile the blockade of the Akt/mTOR pathway occurred in the process. Inhibition of this pathway was induced by cisplatin treatment in the resistant non-small cell lung carcinoma cells. Andrographolide, a natural diterpenoid, promoted the activation of the Akt/mTOR signaling by downregulating PTEN and suppressed autophagy, which subsequently resensitized the resistant cells to cisplatin-mediated apoptosis. Cisplatin treatment in combination with andrographolide significantly prevented the growth of the resistant cells in vivo."

According to the news editors, the research concluded: "These results highlight the involvement of autophagy in cisplatin-resistance development and suggest that inhibition of autophagy via tuning the Akt/mTOR signaling could be a promising strategy in the therapy for cisplatin-resistant non-small cell lung cancer."

For more information on this research see: Inhibition of autophagy by andrographolide resensitizes cisplatin-resistant non-small cell lung carcinoma cells via activation of the Akt/mTOR pathway. Toxicology and Applied Pharmacology, 2016;310();78-86. Toxicology and Applied Pharmacology can be contacted at: Academic Press Inc Elsevier Science, 525 B St, Ste 1900, San Diego, CA 92101-4495, USA. Researchers from Nanjing University Report Findings in Applied Materials & Interfaces (Highly Sensitive Colorimetric Cancer Cell Detection Based on Dual Signal Amplification)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Materials Research - Applied Materials & Interfaces is the subject of a report. According to news reporting out of Nanjing, People's Republic of China, by NewsRx editors, research stated, "Facile and efficient detection of cancer cells at their preclinical stages is one of the central challenges in cancer diagnostics. A direct, rapid, highly sensitive and specific biosensor for detection of cancer biomarkers is desirable in early diagnosis and prognosis of cancer."

Funders for this research include Ministry of Science and Technology of the People's Republic of China, National Natural Science Foundation of China, Priority Academic Program Development of Jiangsu Higher Education Institutions.

Our news journalists obtained a quote from the research from Nanjing University, "In this work, we developed, for the first time, an easy and intuitive dispersion-dominated colorimetric strategy for cancer cell detection based on combining multi-DNA released from an aptamer scaffold with cyclic enzymatic amplification, which was triggered by aptamer DNA conformational switch and demonstrated by non-cross-linking gold nanoparticles (Au NPs) aggregation. First, five kinds of messenger DNAs (mDNAs) were aligned on the cancer cell aptamers modified on magnetic beads (MBs) to form mDNAs-Apt-MBs biocompatible nanosensors. In the presence of target cells, the aptamer would bind to the receptors on the cell membranes, and mDNAs would be released, resulting in the first amplification that one biological binding event would cause the release of multiple kinds of mDNAs simultaneously. After magnetic separation, the released mDNAs were introduced into the cyclic enzymatic amplification to cleave more single strand DNA (ssDNA) fragments. Instead of modification of Au NPs, these fragments and mDNAs could be adsorbed on the surface of Au NPs to prevent particle aggregation and ensure the stability and color of solution in high salt environments. The linear response for HL-60 cells in a concentration range from 10 to 10(4) cells was obtained with a detection limit of four cells in buffer solution. Moreover, the feasibility of the proposed strategy was demonstrated in a diluted serum sample."

According to the news editors, the research concluded: "This dual signal
amplification method can be extended to other types of cancer cells, which has potential application in point-of-care cancer diagnosis."

Our news journalists report that additional information may be obtained by contacting T. Yu, State Key Laboratory of Analytical Chemistry for Life Science and Collaborative Innovation Center of Chemistry for Life Sciences, School of Chemistry and Chemical Engineering, Nanjing University, Nanjing 210023, People's Republic of China. Additional authors for this research include P.P. Dai, J.J. Xu and H.Y Chen.

**Oncology - Colon Cancer**

**Researchers from Nanjing University Report New Studies and Findings in the Area of Colon Cancer (Andrographolide reversed 5-FU resistance in human colorectal cancer by elevating BAX expression)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Oncology - Colon Cancer. According to news reporting originating from Jiangsu, People's Republic of China, by NewsRx correspondents, research stated, "5-FU is the first line therapy for colorectal cancer, however, treatment effect is often hampered by the development of drug resistance or toxicity at high doses. Andrographolide is a natural diterpenoid from Andrographis paniculata which has anti-bacterial, anti-antiviral and anti-inflammation activities."

Financial supporters for this research include National Natural Science Foundation of China, Key Personel of Jiangsu Province, Jiangsu Province Clinical Science and Technology Projects, Priority Academic Program Development of Jiangsu Higher Education Institutions.

Our news editors obtained a quote from the research from Nanjing University, "In the current study, we test the hypothesis that Andrographolide reverses 5-FU resistance in colorectal cancer and examine the underlying mechanism. In vitro and vivo studies indicated that Andrographolide treatment significantly re-sensitizes HCT116/5-FUR cells (HCT116 cells which are 5-FU resistant) to cytotoxicity of 5-FU. Mechanism analysis showed that Andrographolide/5-FU co-treatment elevated apoptosis level of HCT116/5-FUR cells with highly increased level of BAX. By using biotin-Andrographolide pull down and cellular thermal shift assay, we found out that Andrographolide can directly target to BAX. Andrographolide-BAX interaction prevented BAX degradation, enhancing mitochondria-mediated apoptosis thus reversed 5-FU resistance while BAX silence diminished this effect. Further, by analyzing patient samples who received 5-FU involved chemotherapy, we found that expression level of BAX is
correlated with PFS. Our results here provide a novel combination treatment strategy, especially for patients with 5-FU-resistant tumors expressing low level of BAX."

According to the news editors, the research concluded: "Meanwhile, we also proposed that BAX expression may be a predicted and prognosis marker of 5-FU involved chemotherapy."

The news editors report that additional information may be obtained by contacting Q. Xu, Nanjing University, Sch Life Sci, State Key Lab Pharmaceut Biotechnol, Nanjing 210093, Jiangsu, People's Republic of China. Additional authors for this research include W.J. Guo, L.L. Li, Z. Fu, W. Liu, J. Gao, Y.Q. Shu, Q. Xu, Y. Sun and Y.H. Gu.

Researchers from Nantong University Report on Findings in Liver Cancer (High expression of TRIM44 is associated with enhanced cell proliferation, migration, invasion, and resistance to doxorubicin in hepatocellular carcinoma)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Oncology - Liver Cancer. According to news reporting originating in Jiangsu, People's Republic of China, by NewsRx journalists, research stated, "Dysregulation of TRIM44 has been reported to be involved in tumorigenesis, but its role in hepatocellular carcinoma (HCC) remains unclear. In the present study, we investigated the clinicopathological and biological significance of TRIM44 in HCC."

Financial supporters for this research include National Natural Science Foundation of China, Science and Technology Planning Project of Nantong.

The news reporters obtained a quote from the research from Nantong University, "We found that TRIM44 mRNA and protein expression was upregulated in HCC compared with matched normal tissues. Intriguingly, we also found that TRIM44 expression was significantly correlated with tumor size (P < 0.001), vascular invasion (P < 0.001), intrahepatic metastasis (P < 0.001), distant metastasis (P < 0.001), and Ki-67 expression (P < 0.001). Kaplan-Meier analysis showed that high TRIM44 staining was significantly correlated with shorter overall survival (P < 0.001). TRIM44 was an independent predictor of overall survival in patients with HCC. Furthermore, we found that ectopic expression of TRIM44 could promote cell proliferation via accelerating the G1/S phase transition in HCC. Moreover, overexpression of
TRIM44 could enhance the invasive and migratory capacity of HCC cells. Meanwhile, we found that high expression of TRIM44 could enhance resistance of HCC cells to doxorubicin via accelerating NF-kappa B activation.

According to the news reporters, the research concluded: "Our results suggest that TRIM44 may be a novel prognostic indicator and potential therapeutic target of HCC."

For more information on this research see: High expression of TRIM44 is associated with enhanced cell proliferation, migration, invasion, and resistance to doxorubicin in hepatocellular carcinoma. *Tumor Biology*, 2016;37(11):14615-14628. *Tumor Biology* can be contacted at: Springer, Van Godewijckstraat 30, 3311 Gz Dordrecht, Netherlands. *Digestive System Diseases and Conditions - …

Researchers from National Cancer Center Report Recent Findings in Colorectal Neoplasms (Sensitivity of 2-[F-18]fluoro-2-deoxyglucose positron emission tomography for advanced colorectal neoplasms: a large-scale analysis of 7505 asymptomatic ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Digestive System Diseases and Conditions - Colorectal Neoplasms is now available. According to news originating from Tokyo, Japan, by NewsRx correspondents, research stated, "The sensitivity of 2-[F-18]fluoro-2-deoxyglucose positron emission tomography (FDG-PET) for advanced colorectal neoplasms among healthy subjects is not yet fully understood. The present study aimed to clarify the sensitivity by analyzing large-scale data from an asymptomatic screening population."

Our news journalists obtained a quote from the research from National Cancer Center, "A total of 7505 asymptomatic screenees who underwent both FDG-PET and colonoscopy at our Cancer Screening Division between February 2004 and March 2013 were analyzed. FDG-PET and colonoscopy were performed on consecutive days, and each examination was interpreted in a blinded fashion. The results of the two examinations were compared for each of the divided six colonic segments, with those from colonoscopy being set as the reference. The relationships between the sensitivity of FDG-PET and clinicopathological features of advanced neoplasms were also evaluated. Two hundred ninety-one advanced
neoplasms, including 24 invasive cancers, were detected in 262 individuals. Thirteen advanced neoplasms (advanced adenomas) were excluded from the analysis because of the coexistence of lesions in the same colonic segment. The sensitivity, specificity, and positive and negative predictive values of FDG-PET for advanced neoplasms were 16.9% [95% confidence interval (CI) 12.7–21.8%], 99.3% [95% CI 99.2–99.4%], 13.5% [95% CI 10.1–17.6%], and 99.4% [95% CI 99.3–99.5%], respectively. The sensitivity was lower for lesions with less advanced histological grade, of smaller size, and flat-type morphology, and for those located in the proximal part of the colon. FDG-PET is believed to be difficult to use as a primary screening tool in population-based colorectal cancer screening because of its low sensitivity for advanced neoplasms."

According to the news editors, the research concluded: "Even when it is used in opportunistic cancer screening, the limit of its sensitivity should be considered."

The news correspondents report that additional information may be obtained from M. Sekiguchi, Natl Canc Center, Endoscopy Div, Chuo Ku, Tokyo 1040045, Japan. Additional authors for this research include Y. Kakugawa, T. Terauchi, M. Matsumoto, H. Saito, Y. Muramatsu, Y. Saito and T. Matsuda.

**Oncology - Liver Cancer**

**Researchers from National Cancer Institute Describe Findings in Liver Cancer (Drug-eluting beads versus conventional chemoembolization for the treatment of unresectable hepatocellular carcinoma)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Oncology - Liver Cancer have been presented. According to news reporting out of Milan, Italy, by NewsRx editors, research stated, "Solid demonstrations of superior efficacy of drug-eluting beads transarterial chemoembolization with respect to conventional chemoembolization in hepatocellular carcinoma patients are lacking. The aim of the study was to compare these two techniques in two large cohorts of unresectable hepatocellular carcinoma patients."

Funders for this research include National Cancer Institute institutional grants on Hepato-Oncology, Italian Association for Cancer Research (AIRC).

Our news journalists obtained a quote from the research from National Cancer Institute, "A single center series of 249 early/intermediate hepatocellular carcinoma patients
who underwent 'on demand' chemoembolization in the period 2007-2011 was analyzed. Overall survival, time to progression, tumor response rate, and safety were compared between 104 patients who underwent conventional chemoembolization and 145 who underwent drug-eluting beads chemoembolization. Time-to-event data were analyzed using the Cox univariate and multivariate regression. The two cohorts resulted balanced for liver function and tumor stages. Objective response rate was 85.3% after conventional and 74.8% after drug-eluting beads chemoembolization (p=0.039), and median time to progression was 17 (95% confidence interval: 14-21) versus 11 months (9-12), respectively (p <0.001). Treatment regimen was the sole independent predictor of progression at multivariate analysis (hazard ratio=2.01; 1.45-2.80; p<0.001). Median survival was 39 (32-47) and 32 (24-39) months in the two groups, respectively (hazard ratio=1.33; 0.94-1.87; p=0.10), but conventional chemoembolization was significantly associated with a survival advantage in patients with bilobar neoplasia, portal hypertension and alpha fetoprotein above normal limits. No significant differences in severe adverse events were found."

According to the news editors, the research concluded: "In a large series of Western hepatocellular carcinoma patients, drug-eluting beads chemoembolization with 100-300 µm particles did not seem to improve survival in comparison with conventional chemoembolization, which in turn provided better tumor responses and time to progression."

Our news journalists report that additional information may be obtained by contacting A. Facciorusso, Gastroenterology, Surgery and Liver Transplantation Unit, Fondazione Istituto Nazionale Tumori IRCCS-National Cancer Institute, Milan, Italy. Additional authors for this research include L. Mariani, C. Sposito, C. Spreafico, M. Bongini, C. Morosi, T. Cascella, A. Marchiano, T. Camerini, S. Bhoori, F. Brunero, M. Barone and V. Mazzaferro.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1111/jgh.13147. This DOI is a link to an online electronic document that is either free or for purchase.

Keywords for this news article include: Milan, Italy, Europe, Oncology, Carcinomas, Liver Cancer, Chemoembolization.

**Pharmacokinetics**

**Researchers from National Cancer Institute Detail Findings in Pharmacokinetics (Effects of UGT1A1 genotype on the pharmacokinetics, pharmacodynamics, and toxicities of belinostat administered by 48-hour continuous infusion in patients with ...)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Pharmacokinetics is the subject of a report. According to news originating from Bethesda, Maryland, by NewsRx correspondents, research stated, "The
Histone deacetylase inhibitor belinostat is eliminated through glucuronidation by UGT1A1. Polymorphisms that reduce UGT1A1 function could result in increased belinostat exposure and toxicities."

Our news journalists obtained a quote from the research from National Cancer Institute, "We wanted to determine which single-nucleotide polymorphisms alter belinostat exposure and toxicity. In a phase 1 trial (belinostat over 48 hours in combination with cisplatin and etoposide), belinostat (400, 500, 600, or 800 mg/m(2) /24 h, 48-hour continuous infusion) was administered to patients with cancer in combination with cisplatin and etoposide (n=25). Patients were genotyped for UGT1A1 variants associated with reduced function: UGT1A1*6, UGT1A1*28, and UGT1A1*60. End points were associations between UGT1A1 genotype and belinostat pharmacokinetics (PK), toxicities, and global protein lysine acetylation (AcK). Belinostat AUC was increased (p=.003), and t1/2 increased (p=.0009) in UGT1A1*28 and UGT1A1*60 carriers who received more than 400 mg/m(2) /24 h. The incidence of grades 3-4 thrombocytopenia (p=.0081) was associated with UGT1A1 polymorphisms. The US Food and Drug Administration-approved package insert recommends dose adjustment of belinostat for UGT1A1*28. However, our data suggest dose adjustment is also necessary for UGT1A1*60."

According to the news editors, the research concluded: "UGT1A1 polymorphisms were associated with increased systemic belinostat exposure, increased AcK, and increased incidence of toxicities, particularly at doses >400 mg/m(2) /24 h."

For more information on this research see: Effects of UGT1A1 genotype on the pharmacokinetics, pharmacodynamics, and toxicities of belinostat administered by 48-hour continuous infusion in patients with cancer. *Journal of Clinical Pharmacology*, 2015;56(4):461-73. *Journal of Clinical Pharmacology* can be contacted at: SAGE Publications, USA, 2455 Teller Road, Thousand Oaks, CA 91320, USA. Genetics - Medical Genetics

Researchers from National Cancer Institute Report New Studies and Findings in the Area of Medical Genetics (Research participant interest in primary, secondary, and incidental genomic findings)
2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Genetics - Medical Genetics have been published. According to news reporting out of Rockville, Maryland, by NewsRx editors, research stated, "To define the frequency with which adult research participants consent to be offered clinically validated research genetic test results (RR) and incidental findings (IF). Consents were obtained from 506 adults enrolled in one of three studies within the National Cancer Institute Clinical Genetics Branch's Familial Cancer Research Program."

Our news journalists obtained a quote from the research from National Cancer Institute, "A cross-sectional analysis was performed involving the choices indicated on study consents regarding receipt of RR and IF. Ninety-seven percent opted to receive RR and IF. Participants who declined (n = 16) included two cancer survivors who were mutation-positive (1 = RR and 1 = both), eight who knew their primary mutation status (3 = RR; 4 = IF; 1 = both), three nonbloodline relatives (1 = RR; 2 = both), one untested but with the syndromic phenotype (1 = IF), and two parents of an affected child (2 = both). We speculate that these individuals either already had sufficient information, were not prepared to learn more, or felt that the information would not change their personal health-care decision making. Adult research participants from families at high genetic risk for cancer overwhelmingly indicated their preference to receive both RR and IF."

According to the news editors, the research concluded: "Future research will seek to identify the reasons for declining RR and IF and to study the impact of receipt of RR and IF on personal medical decision making."

For more information on this research see: Research participant interest in primary, secondary, and incidental genomic findings. Genetics in Medicine, 2016;18(12):1218-1225. Life Science Research - Molecular and Cellular Biology

Researchers from National Cancer Institute Report New Studies and Findings in the Area of Molecular and Cellular Biology (Direct Regulation of Alternative Splicing by SMAD3 through PCBP1 Is Essential to the Tumor-Promoting Role of TGF-beta)
2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Life Science Research - Molecular and Cellular Biology have been presented. According to news reporting out of Bethesda, Maryland, by NewsRx editors, research stated, "In advanced stages of cancers, TGF-beta promotes tumor progression in conjunction with inputs from receptor tyrosine kinase pathways. However, mechanisms that underpin the signaling cooperation and convert TGF-beta from a potent growth inhibitor to a tumor promoter are not fully understood."

Our news journalists obtained a quote from the research from National Cancer Institute, "We report here that TGF-beta directly regulates alternative splicing of cancer stem cell marker CD44 through a phosphorylated T179 of SMAD3-mediated interaction with RNA-binding protein PCBP1. We show that TGF-beta and EGF respectively induce SMAD3 and PCBP1 to colocalize in SC35-positive nuclear speckles, and the two proteins interact in the variable exon region of CD44 pre-mRNA to inhibit spliceosome assembly in favor of expressing the mesenchymal isoform CD44s over the epithelial isoform CD44E."

According to the news editors, the research concluded: "We further show that the SMAD3-mediated alternative splicing is essential to the tumor-promoting role of TGF-beta and has a global influence on protein products of genes instrumental to epithelial-to-mesenchymal transition and metastasis."

For more information on this research see: Direct Regulation of Alternative Splicing by SMAD3 through PCBP1 Is Essential to the Tumor-Promoting Role of TGF-beta. Molecular Cell, 2016;64(3):549-564. Pharmacokinetics

Researchers from National Cancer Institute Report New Studies and Findings in the Area of Pharmacokinetics (UGT1A1 genotype-dependent dose adjustment of belinostat in patients with advanced cancers using population pharmacokinetic modeling and ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Pharmacokinetics is now available. According to news reporting originating from Bethesda, Maryland, by NewsRx correspondents, research stated, "Belinostat is a second-generation zinc-binding histone deacetylase inhibitor that is approved for peripheral T-cell lymphoma and is currently being studied in small cell lung cancer and other advanced carcinomas as a 48-hour continuous intravenous infusion. Belinostat is predominantly metabolized by UGT1A1, which is polymorphic."
Financial support for this research came from Boeing.

Our news editors obtained a quote from the research from National Cancer Institute, "Preliminary analyses revealed a difference in belinostat clearance based on UGT1A1 genotype. A 2-compartment population pharmacokinetic (PK) model was developed and validated that incorporated the UGT1A1 genotype, albumin, and creatinine clearance on the clearance parameter; body weight was a significant covariate on volume. Simulated doses of 600 and 400 mg/m²/24 h given to patients considered extensive or impaired metabolizers, respectively, provided equivalent AUCs. This model and subsequent simulations supported additional PK/toxicity and pharmacogenomics/toxicity analyses to suggest a UGT1A1 genotype-based dose adjustment to normalize belinostat exposure and allow for more tolerable therapy."

According to the news editors, the research concluded: "In addition, global protein lysine acetylation was modeled with PK and demonstrated a reversible belinostat exposure/response relationship, consistent with previous reports."

For more information on this research see: UGT1A1 genotype-dependent dose adjustment of belinostat in patients with advanced cancers using population pharmacokinetic modeling and simulation. Journal of Clinical Pharmacology, 2015;56(4):450-60. Journal of Clinical Pharmacology can be contacted at: SAGE Publications, USA, 2455 Teller Road, Thousand Oaks, CA 91320, USA. Heart Disorders and Diseases - Heart Attack

Researchers from National Cerebral and Cardiovascular Center Describe Findings in Heart Attack (Lipoprotein apheresis is essential for managing pregnancies in patients with homozygous familial hypercholesterolemia: Seven case series and ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Heart Disorders and Diseases - Heart Attack is the subject of a report. According to news reporting out of Osaka, Japan, by NewsRx editors, research stated, "For patients with homozygous familial hypercholesterolemia (HoFH), atherogenic lipoprotein changes and increased stress on cardiovascular system during pregnancy may pose substantial risk for both the mother and her fetus. Although lipoprotein apheresis (LA) is
reported as the most effective therapy to control LDL-C levels during pregnancy in HoFH patients, only case reports have been published, and there is no guidance for management."

Financial support for this research came from Sapienza University of Rome.

Our news journalists obtained a quote from the research from National Cerebral and Cardiovascular Center, "We report twelve pregnancies and ten deliveries in seven patients with HoFH, and compare the clinical outcomes between patients who received LA during pregnancy and those who did not. One patient who refused LA during pregnancy died from acute myocardial infarction after delivery. Another patient whose adherence to LA was poor also died of myocardial infarction during pregnancy. One patient who initiated LA at the age of 18 had to discontinue LA due to severe symptoms of angina pectoris during pregnancy. Another had symptoms of nausea, hypotension, and bradycardia with increased levels of serum bradykinin during a dextran sulfate cellulose absorption-based LA procedure. Although two of the other three patients had already had coronary artery disease by the time of pregnancy, early initiation of LA from childhood and good adherence to it during pregnancy resulted in the delivery of healthy infants without adverse effects. LA is essential for managing pregnancy safely in patients with HoFH."

According to the news editors, the research concluded: "Increasing numbers of documented cases, including ours, will be helpful to guide future therapeutic decisions."

For more information on this research see: Lipoprotein apheresis is essential for managing pregnancies in patients with homozygous familial hypercholesterolemia: Seven case series and discussion. *Atherosclerosis*, 2016;254():179-183. *Atherosclerosis* can be contacted at: Elsevier Ireland Ltd, Elsevier House, Brookvale Plaza, East Park Shannon, Co, Clare, 00000, Ireland. (Elsevier - www.elsevier.com; Atherosclerosis - www.journals.elsevier.com/atherosclerosis/)

**Oncology - Lung Cancer**

Researchers from National Dong Hwa University Report Findings in Lung Cancer (Excavatolide B inhibits nonsmall cell lung cancer proliferation by altering peroxisome proliferator activated receptor gamma expression and PTEN/AKT/NF-Kb expression)
2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Oncology - Lung Cancer have been published. According to news reporting from Hualien, Taiwan, by NewsRx journalists, research stated, "Marine organisms are proven to be rich source of secondary metabolites that can be used to treat various diseases. Excavatolide B (Exc.B), the most abundant metabolite was found in the marine coral Briareum excavatum exhibits cytotoxic effects against lung cancer cell."

Financial support for this research came from National Science Council.

The news correspondents obtained a quote from the research from National Dong Hwa University, "Treatment of the A549 cells with Exc.B significantly reduced its cell viability and induced cell cycle arrest at subG1 phase in a dose-and time-dependent manner, respectively. Apoptosis induction by Exc.B was further confirmed by decreased pro-caspase 3 expressions and increased proteolytic cleavage of poly (ADP-ribose) polymerase (PARP) expression. Furthermore, Exc.B increased reactive oxygen species (ROS) and reactive nitrogen species (RNS) and also decreased the antioxidant enzymes such as, Catalase, GPx, SOD, GST, and GSH. The proteomic analysis data revealed that total thirty six proteins were altered by Exc.B. STRING database showed that most of the altered proteins have no interaction between each other. Based on these data, KSR1, RuVBL2, PPAR-g, and Tenascin X proteins were chosen to validate the 2DE data by Western blotting. Additional experiments demonstrated that Exc.B induced PTEN expression and inhibited pAKT and NF-kB expression."

According to the news reporters, the research concluded: "These results provide a novel insight into mechanisms underlying the inhibition of A549 cells growth by excavatolide B. ? 2016 Wiley Periodicals, Inc. Environ Toxicol 32:290-301."

Our news journalists report that additional information may be obtained by contacting B.K. Velmurugan, Dept. of Life Science and Institute of Biotechnology, National Dong Hwa University, Hualien, 974, Taiwan. Additional authors for this research include H.H. Yang, P.J. Sung and C.F Weng.

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Mental Health Diseases and Conditions - Bipolar Disorders have been published. According to news reporting originating in Tokyo, Japan, by NewsRx journalists, research stated, "The intronic single-nucleotide polymorphism rs10994336 of the ankyrin 3 gene (ANK3) is one of the genome-wide supported risk variants for bipolar disorder (BD), and the T-allele of rs10761482 is also reported to have relevance to BD. We investigated the effect of ANK3 rs10761482 genetic variation on brain structure."

The news reporters obtained a quote from the research from the National Institute of Neuroscience, "Subjects were 43 BD patients and 229 healthy volunteers. We evaluated the effects of ANK3 rs10761482 genetic variation on diagnosis, and of the genotype-by-diagnosis interaction on the brain structure and the degree of age-related brain atrophy on magnetic resonance imaging data evaluated by voxel-based morphometry. BD patients showed significantly lower fractional anisotropy value in the bilateral parietal regions, left fronto-occipital fasciculus, and corpus callosum, compared to healthy subjects. Further, we found considerable decreases of fractional anisotropy in the forceps minor in non-T-allele BD patients compared with the T-carrier patient group. We also found significant lessening of age-related brain atrophy in the T-allele carrier groups compared with the non-T-allele carrier groups in the area around the cerebrospinal space, cingulate cortices, and cerebellum. Our results suggest the influence of the ANK3 on age-related brain atrophy."

According to the news reporters, the research concluded: "The ankyrin 3 genotype may be associated with pathogenesis of age-related neurodegeneration, and, in part, of BD."

Our news correspondents report that additional information may be obtained by contacting M. Ota, Natl Center Neurol & Psychiat, Natl Inst Neurosci, Dept. of Mental Disorder Res, Kodaira, Tokyo 1878502, Japan. Additional authors for this research include H. Hori, N. Sato, F. Yoshida, K. Hattori, T. Teraishi and H. Kunugi.

Neurodegenerative Diseases and Conditions -

Researchers from National Institute of Sensory Organs Report Findings in Amyotrophic Lateral Sclerosis (Significance of optineurin mutations in glaucoma and other diseases)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Neurodegenerative Diseases and Conditions - Amyotrophic Lateral Sclerosis are presented in a new report. According to news reporting from Tokyo, Japan, by NewsRx journalists, research stated, "Glaucoma is one of the leading causes of bilateral
blindness, affecting nearly 57 million people worldwide. Glaucoma is characterized by a progressive loss of retinal ganglion cells and is often associated with intraocular pressure (IOP)."

Financial supporters for this research include Japanese Ministry of Health, Labour and Welfare, Japan Agency for Medical Research and Development, Japan Society for the Promotion of Science.

The news correspondents obtained a quote from the research from the National Institute of Sensory Organs, "Normal tension glaucoma (NTG), marked by normal IOP but progressive glaucoma, is incompletely understood. In 2002, Sarfarazi et al. identified FIP-2 gene mutations responsible for hereditary NTG, renaming this gene 'optineurin' (OPTN). Further investigations by multiple groups worldwide showed that OPTN is involved in several critical cellular functions, such as NF-κB regulation, autophagy, and vesicle transport. Recently, OPTN mutations were found to cause amyotrophic lateral sclerosis (ALS). Surprisingly, a mutation in the OPTN interacting protein, i.e., the duplication of TANK binding protein 1 (TBK1) gene, also can cause both NTG and ALS. These phenotypically distinct neuronal diseases are now merging into one common pathological mechanism by these two genes. TBK1 inhibition has emerged as a potential therapy for NTG. In this manuscript, we focus on the OPTN E50K mutation, the most common mutation for NTG, to describe the molecular mechanism of NTG by expressing a mutant Optn gene in cells and genetically modified mice. Patient iPS cells were developed and differentiated into neural cells to observe abnormal behavior and the impact of the E50K mutation. These in vitro studies were further extended to identify the inhibitors BX795 and amlexanox, which have the potential to reverse the disease-causing phenomenon in patient's neural cells."

According to the news reporters, the research concluded: "Here we show for the first time that amlexanox protects RGC5 in Optn E50K knock-in mice."

Our news journalists report that additional information may be obtained by contacting T. Iwata, Natl Hosp Organization Tokyo Med Center, Natl Inst Sensory Organs, Div Mol & Cellular Biol, Tokyo, Japan. Additional authors for this research include M. Nakayama, D. Iejima, K. Kawase and T. Iwata.

Researchers from National Institute of Technology Report Details of New Studies and Findings in the Area of Apoptosis (Bacopa monnieri-Induced Protective Autophagy Inhibits Benzo[a]pyrene-Mediated Apoptosis)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Apoptosis is now available. According to news reporting out of Rourkela, India, by NewsRx editors, research stated, "Benzo[a]pyrene (B[a]P) is capable of inducing oxidative stress and cellular injuries leading to cell death and associates with a significant risk of cancer development. Prevention of B[a]P-induced cellular toxicity with herbal compound through regulation of mitochondrial oxidative stress might protect cell death and have therapeutic benefit to human health."

Our news journalists obtained a quote from the research from the National Institute of Technology, "In this study, we demonstrated the cytoprotective role of Bacopa monnieri (BM) against B[a]P-induced apoptosis through autophagy induction. Pretreatment with BM rescued the reduction in cell viability in B[a]P-treated human keratinocytes (HaCaT) cells indicating the cytoprotective potential of BM against B[a]P. Moreover, BM was found to inhibit B[a]P-mediated reactive oxygen species (ROS)-induced apoptosis activation in HaCaT cells. Furthermore, BM was found to preserve mitochondrial membrane potential and inhibited release of cytochrome c in B[a]P-treated HaCaT cells. Bacopa monnieri induced protective autophagy; we knocked down Beclin-1, and data showed that BM was unable to protect from B[a]P-induced mitochondrial ROS-mediated apoptosis in Beclin-1-deficient HaCaT cells. Moreover, we established that B[a]P-induced damaged mitochondria were found to colocalize and degraded within autolysosomes in order to protect HaCaT cells from mitochondrial injury."

According to the news editors, the research concluded: "B[a]P-induced apoptosis was rescued by BM treatment and provided cytoprotection through Beclin-1-dependent autophagy activation."

Our news journalists report that additional information may be obtained by contacting S.K. Bhutia, Natl Inst Technol, Dept. of Life Sci, Rourkela 769008, Odisha, India. Additional authors for this research include P.P. Naik, A. Nayak, P.K. Panda, S. Mukhopadhyay, N. Sinha and S.K. Bhutia.

Keywords for this news article include: Rourkela, India, Asia, Benzopyrenes, Risk and Prevention, Benzo(a)pyrene, Apoptosis, National Institute of Technology.

Nutritional and Metabolic Diseases and Conditions...

Researchers from National Institutes of Health Detail New Studies and Findings in the Area of Smith-Lemli-Opitz Syndrome (Modeling Smith-Lemli-Opitz syndrome with induced pluripotent stem cells reveals a causal role for Wnt/b-catenin defects in...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Nutritional and Metabolic Diseases and Conditions - Smith-Lemli-Opitz Syndrome is the subject of a report. According to news reporting originating from Bethesda, Maryland, by NewsRx correspondents, research stated, "Smith-Lemli-Opitz syndrome (SLOS) is a malformation disorder caused by mutations in DHCR7, which impair the reduction of 7-dehydrocholesterol (7DHC) to cholesterol. SLOS results in cognitive impairment, behavioral abnormalities and nervous system defects, though neither affected cell types nor impaired signaling pathways are fully understood."

Our news editors obtained a quote from the research from the National Institutes of Health, "Whether 7DHC accumulation or cholesterol loss is primarily responsible for disease pathogenesis is also unclear. Using induced pluripotent stem cells (iPSCs) from subjects with SLOS, we identified cellular defects that lead to precocious neuronal specification within SLOS derived neural progenitors. We also demonstrated that 7DHC accumulation, not cholesterol deficiency, is critical for SLOS-associated defects. We further identified downregulation of Wnt/b-catenin signaling as a key initiator of aberrant SLOS iPSC differentiation through the direct inhibitory effects of 7DHC on the formation of an active Wnt receptor complex."

According to the news editors, the research concluded: "Activation of canonical Wnt signaling prevented the neural phenotypes observed in SLOS iPSCs, suggesting that Wnt signaling may be a promising therapeutic target for SLOS."

For more information on this research see: Modeling Smith-Lemli-Opitz syndrome with induced pluripotent stem cells reveals a causal role for Wnt/b-catenin defects in neuronal cholesterol synthesis phenotypes. *Nature Medicine*, 2016;22(4):388-96. (Nature Publishing Group - www.nature.com/nm/)

The news editors report that additional information may be obtained by contacting K.R. Francis, Program in Genomics of Differentiation, The Eunice Kennedy Shriver National Institute of Child Health and Human Development, National Institutes of Health (NIH), Bethesda, Maryland, United States. Researchers from National Institutes of Health Provide Details of New Studies and Findings in the Area of Adrenal Cortical Steroids (Effects of Systemically Administered Hydrocortisone on the Human Immunome)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Drugs and Therapies - Adrenal Cortical Steroids. According to news reporting originating in Bethesda, Maryland, by NewsRx journalists, research stated, "Corticosteroids have been used for decades to modulate inflammation therapeutically, yet there is a paucity of data on their effects in humans. We examined the changes in cellular and molecular immune system parameters, or 'immunome', in healthy humans after systemic corticosteroid administration."

The news reporters obtained a quote from the research from the National Institutes of Health, "We used multiplexed techniques to query the immunome in 20 volunteers at baseline, and after intravenous hydrocortisone (HC) administered at moderate (250 mg) and low (50 mg) doses, to provide insight into how corticosteroids exert their effects. We performed comprehensive phenotyping of 120 lymphocyte subsets by high dimensional flow cytometry, and observed a decline in circulating specific B and T cell subsets, which reached their nadir 4-8 hours after administration of HC. However, B and T cells rebounded above baseline 24 hours after HC infusion, while NK cell numbers remained stable. Whole transcriptome profiling revealed down regulation of NF-kB signaling, apoptosis, and cell death signaling transcripts that preceded lymphocyte population changes, with activation of NK cell and glucocorticoid receptor signaling transcripts."

According to the news reporters, the research concluded: "Our study is the first to systematically characterize the effects of corticosteroids on the human immunome, and we demonstrate that HC exerts differential effects on B and T lymphocytes and natural killer cells in humans."

For more information on this research see: Effects of Systemically Administered Hydrocortisone on the Human Immunome. Scientific Reports, 2016;6():23002. (Nature Publishing Group - www.nature.com/; Scientific Reports - www.nature.com/srep/)

Researchers from National Institutes of Health Report Recent Findings in Vitamin D Deficiency (Vitamin D Deficiency Is Associated With Endothelial Dysfunction and Increases Type I Interferon Gene Expression in a Murine Model of Systemic Lupus ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Nutritional and Metabolic Diseases and Conditions - Vitamin D Deficiency is now available. According to news reporting originating from Bethesda, Maryland, by NewsRx correspondents, research stated, "Patients with systemic lupus erythematosus (SLE) have an increased risk of cardiovascular disease (CVD) and impaired endothelial repair. Although vitamin D deficiency is associated with increased CVD risk in the general population, a causal relationship has not been demonstrated."

Our news editors obtained a quote from the research from the National Institutes of Health, "We aimed to determine whether vitamin D deficiency directly modulates endothelial
dysfunction and immune responses in a murine model of SLE. Vitamin D deficiency was induced in lupus-prone MRL/lpr mice by dietary restriction for 6 weeks. Endothelium-dependent vasorelaxation was quantified using aortic ring myography, and endothelial repair mechanisms were assessed by evaluating the phenotype and function of bone marrow endothelial progenitor cells (EPCs) and with the use of an in vivo Matrigel plug model. Lupus disease activity was determined by evaluating expression of interferon-stimulated genes (ISGs) in splenic tissue, positivity for serum autoantibodies, and renal histology. To validate the findings, expression of ISGs was also measured in whole blood from vitamin D-deficient and vitamin D-sufficient patients with SLE. Vitamin D deficiency resulted in impaired endothelium-dependent vasorelaxation and decreases in neoangiogenesis without a change in the total number of EPCs. There were no differences in anti-double-stranded DNA titers, proteinuria, or glomerulonephritis (activity or chronicity) between vitamin D-deficient or sufficient mice. Vitamin D deficiency was associated with a trend toward increased ISG expression both in mice and in patients with SLE."

According to the news editors, the research concluded: "These findings indicate that vitamin D deficiency is associated with hampered vascular repair and reduced endothelial function, and may modulate type I interferon responses."

For more information on this research see: Vitamin D Deficiency Is Associated With Endothelial Dysfunction and Increases Type I Interferon Gene Expression in a Murine Model of Systemic Lupus Erythematosus. Arthritis & Rheumatology, 2016;68(12):2929-2935. Arthritis & Rheumatology can be contacted at: Wiley-Blackwell, 111 River St, Hoboken 07030-5774, NJ, USA.

The news editors report that additional information may be obtained by contacting M.J. Kaplan, National Institutes of Health, Bethesda, MD 20892, United States. Perceptual Diseases and Conditions - Prosopagnosia

Researchers from National Neurology Institute Report Findings in Prosopagnosia [Congenital Prosopagnosia Is Associated With A Genetic Variation In The Oxytocin Receptor (oxtr) Gene: An Exploratory Study]

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Perceptual Diseases and Conditions - Prosopagnosia. According to news originating from Pavia, Italy, by NewsRx correspondents, research stated, "Face-recognition deficits, referred to with the term prosopagnosia (i.e., face
blindness), may manifest during development in the absence of any brain injury (from here the term congenital prosopagnosia, CP). It has been estimated that approximately 2.5% of the population is affected by face-processing deficits not depending on brain lesions, and varying a lot in severity."

Financial supporters for this research include FIRB, Italian Ministry of Education, University and Research.

Our news journalists obtained a quote from the research from National Neurology Institute, "The genetic bases of this disorder are not known. In this study we tested for genetic association between single-nucleotide polymorphisms (SNPs) in the oxytocin receptor gene (OXTR) and CP in a restricted cohort of Italian participants. We found evidence of an association between the common genetic variants rs53576 and rs2254298 OXTR SNPs and prosopagnosia. This association was also found when including an additional group of German individuals classified as prosopagnosic in the analysis."

According to the news editors, the research concluded: "Our preliminary data provide initial support for the involvement of genetic variants of OXTR in a relevant cognitive impairment, whose genetic bases are still largely unexplored."

The news correspondents report that additional information may be obtained from Z. Cattaneo, Brain Connect Center, C Mondino Natl Neurol Inst, Pavia, Italy. Additional authors for this research include R. Daini, M. Malaspina, F. Manai, M. Lillo, V. Fermi, S. Schiavi, B. Suchan and S. Comincini.

Central Nervous System Diseases and Conditions -…

Researchers from Neurological Institute Detail New Studies and Findings in the Area of Moyamoya Disease (Research Progresses in Understanding the Pathophysiology of Moyamoya Disease)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Central Nervous System Diseases and Conditions - Moyamoya Disease. According to news originating from Milan, Italy, by NewsRx correspondents, research stated, "The pathogenesis of moyamoya disease (MMD) is still
unknown. The detection of inflammatory molecules such as cytokines, chemokines and growth factors in MMD patients' biological fluids supports the hypothesis that an abnormal angiogenesis is implicated in MMD pathogenesis."

Our news journalists obtained a quote from the research from Neurological Institute, "However, it is unclear whether these anomalies are the consequences of the disease or rather causal factors as well as these mechanisms remain insufficient to explain the pathophysiology of MMD. The presence of a family history in about 9-15% of Asian patients, the highly variable incidence rate between different ethnic and sex groups and the age of onset support the role of genetic factors in MMD pathogenesis. However, although some genetic loci have been associated with MMD, few of them have been replicated in independent series. Recently, RNF213 gene was shown to be strongly associated with MMD occurrence with a founder effect in East Asian patients. However, the mechanisms leading from RNF213 mutations to MMD clinical features are still unknown. The research on pathogenic mechanism of MMD is in its infancy. MMD is probably a complex and heterogeneous disorder, including different phenotypes and genotypes, in which more than a single factor is implicated."

According to the news editors, the research concluded: "Since the diagnosis of MMD is rapidly increasing worldwide, the development of more efficient stratifying risk systems, including both clinical but also biological drivers became imperative to improve our ability of predict prognosis and to develop mechanism-tailored interventions."

The news correspondents report that additional information may be obtained from A. Bersano, Cerebrovascular Disease Unit, IRCCS Foundation C. Besta, Neurological Institute, Milan, Italy. Additional authors for this research include S. Guey, G. Bedini, S. Nava, D. Herve, P. Vajkoczy, T. Tatlisumak, M. Sareela, A. van der Zwan, C.J. Klijn, K.P. Braun, A. Kronenburg, F. Acerbi, M.M. Brown, L. Calviere, C. Cordonnier, H. Henon, L. Thines and Kh.

Hematology - Blood Coagulation Factors

Researchers from New York University Detail New Studies and Findings in the Area of Blood Coagulation Factors (A novel approach to the management of carotid blowout syndrome: the use of thrombin in a case of failed covered stenting)
2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Hematology - Blood Coagulation Factors is now available. According to news originating from Brooklyn, New York, by NewsRx correspondents, research stated, "Acute hemorrhage relating to an expanding pseudoaneurysm of the carotid artery is referred to as carotid blowout syndrome (CBS). CBS is associated with a high morbidity and mortality."

Our news journalists obtained a quote from the research from New York University, "We describe the case of a patient who presented with dysphagia and a pulsatile mass in the neck. Imaging revealed a pseudoaneurysm originating from the bifurcation of the distal right common carotid artery. On neuroangiography the patient lacked sufficient collaterals to allow for vessel sacrifice. A decision was made to use covered stents to prevent flow into the pseudoaneurysm while maintaining vessel patency. Despite placement of multiple covered stents there was residual slow filling of the pseudoaneurysm. We augmented this therapy with direct percutaneous thrombin injection into the pseudoaneurysm. This resulted in complete thrombosis of the pseudoaneurysm."

According to the news editors, the research concluded: "For recalcitrant lesions in which the usual methods of stopping blood flow to the pseudoaneurysmal sac fail, an adjuvant approach with thrombin should be considered."

The news correspondents report that additional information may be obtained from N. Sablani, New York University, Medical Center, Dept. of Internal Med, Brooklyn, NY, United States. Additional authors for this research include G. Jain, M.M. Hasan, K. Sivakumar, S. Feuerwerker, K. Arcot and J. Farkas.

Keywords for this news article include: Brooklyn, New York, United States, North and Central America, Blood Coagulation Factors, Serine Endopeptidases, Enzymes and Coenzymes, Peptide Hydrolases, Hematology, Angiology, Thrombin, New York University.

Researchers from New York University Detail New Studies and Findings in the Area of Sexual and Reproductive Health (Contextual factors in geosocial-networking smartphone application use and engagement in condomless anal intercourse among gay, ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Health and Medicine - Sexual and Reproductive Health are discussed in a new report. According to news originating from New York City, New York, by NewsRx correspondents, research stated, "Geosocial-networking smartphone applications (apps) have been used increasingly by men who have sex with men (MSM) to meet new sexual partners. The purpose of this study was to examine associations between contexts of
app use (e.g. using apps when drinking) and condomless anal intercourse among a sample of MSM who use these apps."

Our news journalists obtained a quote from the research from New York University, "MSM (n = 174) in New York City were recruited through Grindr, a geosocial-networking app popular among MSM, using broadcast advertisements asking MSM to complete an Internet-based survey about their app use and sexual behaviours. Log-binomial regression models were fit to assess the association between each of the six app-use contexts (e.g. using apps when lonely, when drinking) and engagement in condomless insertive and receptive anal intercourse with one or more partners in the past 3 months. Engagement in condomless receptive and insertive anal intercourse with one or more partners in the preceding 3 months was common (39.7% and 43.1% respectively) and was associated with several app-use contexts. For example, significant associations (P < 0.05) were observed between alcohol and other drug use when using these apps and engagement in condomless receptive and insertive anal intercourse."

According to the news editors, the research concluded: "Given that 57.5% of respondents had engaged in condomless anal intercourse in the preceding 3 months and the associations of app-use contexts with condomless sexual behaviours, these findings suggest that reductions in substance use may lead to safer sexual practices among MSM who use apps to meet sexual partners."

The news correspondents report that additional information may be obtained from W.C. Goedel, New York University, Coll Arts & Sci, Dept. of Sociol, New York, NY 10003, United States.

Keywords for this news article include: New York City, New York, United States, North and Central America, Sexual and Reproductive Health, Health and Medicine, New York University.

Life Science Research - Biosocieties

Researchers from New York University Report Details of New Studies and Findings in the Area of Biosocieties (Big data, small kids: Medico-scientific, familial and advocacy visions of human brains)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Life Science Research - Biosocieties is the subject of a report. According to news originating from New York City, New York, by NewsRx editors, the research stated, "On the basis of anthropological fieldwork in a US pediatric neuroscience laboratory, this article traces the recent move from studies of individual diagnostic pathologies like ADHD, Tourette or autism spectrum disorder to the rapid creation of innovative interdisciplinary research coalitions and collaborations that both produce and utilize big data techniques in order to map the human connectome. By analogy with the human genome,
connectome studies require new ways to imagine and image complex and multivalent neurocircuits in which brain scans of those with and without diagnoses provide data points, open to recombination with other forms of data."

Our news journalists obtained a quote from the research from New York University, "Emergent expert understandings of the connectome are only minimally related to what families who enroll their diagnosed children in fMRI studies understand. Likewise, young adult self-advocates with the same diagnoses on which the neuroscientists are now working use 'brain talk' to stake their own ethical claims."

According to the news editors, the research concluded: "I argue that this epistemological gap among medico-scientific, familial and advocacy visions of human brains provides a mobile space of creativity as well as misunderstanding."

The news correspondents report that additional information may be obtained from R. Rapp, New York University, Dept. of Anthropol, New York, NY 10011, United States.

**Drugs and Therapies - Antimicrobials**

**Researchers from Nicolaus Copernicus University Describe Findings in Antimicrobials (Antimicrobial properties of biosynthesized silver nanoparticles studied by flow cytometry and related techniques)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Drugs and Therapies - Antimicrobials have been published. According to news reporting from Torun, Poland, by NewsRx journalists, research stated, "This work reports the effect of silver bionanoparticles (Bio(AgNPs) synthesized by Actinobacteria CGG 11n on selected Gram (+) and Gram (-) bacteria. Flow cytometry, classical antibiogram method and fluorescent microscopy approach was used for evaluation of antimicrobial activity of Bio(AgNPs) and their combination with antibiotics."

The news correspondents obtained a quote from the research from Nicolaus Copernicus University, "Furthermore, the performed research specified the capacity of flow cytometry method as an alternative to the standard ones and as a complementary method to electromigration techniques. The study showed antibacterial activity of both BioAgNPs and the combination of antibiotics/BioAgNPs against all the tested bacteria strains in comparison with a diffusion, dilution and bioautographic methods."

According to the news reporters, the research concluded: "The synergistic effect of
antibiotics/BioAgNPs combination (e.g. kanamycin, ampicillin, neomycin and streptomycin) was found to be more notable against *Pseudomonas aeruginosa* representing a prototype of multi-drug resistant 'superbugs' for which effective therapeutic options are very limited."

Our news journalists report that additional information may be obtained by contacting V. Railean-Plugaru, Dept. of Environmental Chemistry and Bioanalytics, Faculty of Chemistry, Nicolaus Copernicus University, Torun, Poland. Additional authors for this research include P. Pomastowski, K. Rafinska, M. Wypij, W. Kupczyk, H. Dahm, M. Jackowski and B. Buszewski.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1002/elps.201500507. This DOI is a link to an online electronic document that is either free or for purchase.

**Drugs and Therapies - Mitotic Inhibitors**

**Researchers from Ningxia Medical University Describe Findings in Mitotic Inhibitors (CD44 Receptor Targeting and Endosomal pH-Sensitive Dual Functional Hyaluronic Acid Micelles for Intracellular Paclitaxel Delivery)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Drugs and Therapies - Mitotic Inhibitors is now available. According to news reporting originating from Yinchuan, People's Republic of China, by NewsRx correspondents, research stated, "A novel CD44 receptor targeting and endosome pH-sensitive dual functional hyaluronic acid deoxycholic acid histidine (HA-DOCA-His) micellar system was designed for intracellular paclitaxel (PTX) delivery. The HA-DOCA-His micelles exhibited desirable endosome pH (5.0-6.0)-induced aggregation and deformation behavior verified by size distribution, critical micellar concentration, and zeta potential changes."

Financial support for this research came from National Natural Science Foundation of China.

Our news editors obtained a quote from the research from Ningxia Medical University, "The HA-DOCA-His micelles presented excellent encapsulation efficiency and loading capacity of 90.0% and 18.9% for PTX, respectively. The PTX release from HA-DOCA-His micelles was pH-dependent, with more rapid PTX release at pH 6.0 and 5.0 than those at pH 7.4 and 6.5. The cellular uptake performance of HA-DOCA-His micelles was enhanced comparing with pH-insensitive HA-DOCA micelles by qualitative and quantitative measurements. HA-DOCA-His micelles could be taken up via CD44-receptor mediated endocytosis, transported into endosomes, and triggered drug release to cytoplasm. In vitro cytotoxicity study exhibited PTX-loaded HA-DOCA-His micelles were more active in tumor
cell growth inhibition in MCF-7 cells at pH 5.8 than those at pH 6.8 and pH 7.4. A superior antitumor efficacy was demonstrated with HA-DOCA-His micelles in a MCF-7 breast tumor model."

According to the news editors, the research concluded: "These indicated that the dual functional HA-DOCA-His micelles combined targeted intracellular delivery and endosomal release strategies could be developed as a promising nanocarrier for anticancer efficacy improvement of PTX."

For more information on this research see: CD44 Receptor Targeting and Endosomal pH-Sensitive Dual Functional Hyaluronic Acid Micelles for Intracellular Paclitaxel Delivery. *Molecular Pharmaceutics*, 2016;13(12):4209-4221. *Molecular Pharmaceutics* can be contacted at: Amer Chemical Soc, 1155 16TH St, NW, Washington, DC 20036, USA.

The news editors report that additional information may be obtained by contacting Y.H. Liu, Ningxia Med Univ, Key Lab Hui Ethn Med Modernizat, Minist Educ, Yinchuan 750004, People's Republic of China. Additional authors for this research include C.M. Zhou, W.P. Wang, J.H. Yang, H. Wang, W. Hong and Y. Huang.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1021/acs.molpharmaceut.6b00870. This DOI is a link to an online electronic document that is either free or for purchase.

**Surgery - Hysterectomy**

**Researchers from Northeast Normal University Provide Details of New Studies and Findings in the Area of Hysterectomy (The Association between Endometriosis, Tubal Ligation, Hysterectomy and Epithelial Ovarian Cancer: Meta-Analyses)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Surgery - Hysterectomy. According to news reporting originating from Changchun, People's Republic of China, by NewsRx correspondents, research stated, "To investigate the association between endometriosis, tubal ligation, hysterectomy and epithelial ovarian cancer. Relevant published literatures were searched in PubMed, ProQuest, Web of Science and Medline databases during 1995-2016."

Our news editors obtained a quote from the research from Northeast Normal University, "Heterogeneity was evaluated by I-2 statistic. Publication bias was tested by funnel plot and Egger's test. Odds ratio and 95% CI were used to assess the association strength. The statistical analyses in this study were accomplished by STATA software package. A total of 40,609 cases of epithelial ovarian cancer and 368,452 controls in 38 publications were included. The result suggested that endometriosis was associated with an increased risk of epithelial ovarian cancer (OR = 1.42, 95% CI = 1.28-1.57), tubal ligation was associated with a decreased
risk of epithelial ovarian cancer (OR = 0.70, 95% CI = 0.60-0.81), while hysterectomy show no relationship with epithelial ovarian cancer (OR = 0.97, 95% CI = 0.81-1.14). A stratified analysis showed there were associations between endometriosis and the increased risk of epithelial ovarian cancer for studies conducted in USA and Europe. Meanwhile, there were associations between tubal ligation and the decreased risk of epithelial ovarian cancer for studies conducted in USA, Asia, Europe and Australia."

According to the news editors, the research concluded: "The result indicated that endometriosis was a risk factor of epithelial ovarian cancer whereas tubal ligation was a protective risk factor of epithelial ovarian cancer, hysterectomy may have no relationship with epithelial ovarian cancer."

The news editors report that additional information may be obtained by contacting C.P. Wang, Northeast Normal Univ, Sch Math & Stat, Changchun 130024, People's Republic of China. Additional authors for this research include Z.Z. Liang, X. Liu, Q. Zhang and S. Li.

Keywords for this news article include: Changchun, People's Republic of China, Asia, Risk and Prevention, Hysterectomy, Oncology, Surgery, Cancer, Northeast Normal University.

Eye Diseases and Conditions - Age-Related Macular...

Researchers from Northwestern University Detail Findings in Age-Related Macular Degeneration (Macular atrophy in patients with long-term anti-VEGF treatment for neovascular age-related macular degeneration)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Eye Diseases and Conditions - Age-Related Macular Degeneration are discussed in a new report. According to news reporting out of Chicago, Illinois, by NewsRx editors, research stated, "PurposeTo identify the prevalence and progression of macular atrophy (MA) in neovascular age-related macular degeneration (AMD) patients under long-term anti-vascular endothelial growth factor (VEGF) therapy and to determine risk factors. MethodThis retrospective study included patients with neovascular AMD and 30 anti-VEGF injections."

Financial support for this research came from Novartis.

Our news journalists obtained a quote from the research from Northwestern University, "Macular atrophy (MA) was measured using near infrared and spectral-domain optical coherence tomography (SD-OCT). Yearly growth rate was estimated using square-root transformation to adjust for baseline area and allow for linearization of growth rate. Multiple regression with Akaike information criterion (AIC) as model selection criterion was used to estimate the influence of various parameters on MA area. ResultsForty-nine eyes (47 patients, mean age 7714) were included with a mean of 48 +/- 13 intravitreal anti-VEGF injections..."
(ranibizumab: 37 +/- 11, aflibercept: 11 +/- 6, mean number of injections/year 8 +/- 2.1) over a mean treatment period of 6.2 +/- 1.3 years (range 4-8.5). Mean best-corrected visual acuity improved from 57 +/- 17 letters at baseline (= treatment start) to 60 +/- 16 letters at last follow-up. The MA prevalence within and outside the choroidal neovascularization (CNV) border at initial measurement was 45% and increased to 74%. Mean MA area increased from 1.8 +/- 2.7 mm(2) within and 0.5 +/- 0.98 mm(2) outside the CNV boundary to 2.7 +/- 3.4 mm(2) and 1.7 +/- 1.8 mm(2), respectively. Multivariate regression determined posterior vitreous detachment (PVD) and presence/development of intraretinal cysts (IRCs) as significant factors for total MA size (R-2 = 0.16, p=0.02). Macular atrophy (MA) area outside the CNV border was best explained by the presence of reticular pseudodrusen (RPD) and IRC (R-2 = 0.24, p=0.02).

Conclusion: A majority of patients show MA after long-term anti-VEGF treatment.

According to the news editors, the research concluded: "Reticular pseudodrusen (RPD), IRC and PVD but not number of injections or treatment duration seem to be associated with the MA size."

Our news journalists report that additional information may be obtained by contacting M.R. Munk, Northwestern University, Dept. of Ophthalmol, Feinberg Sch Med, Chicago, IL 60611, United States. Additional authors for this research include L. Ceklic, A. Ebneter, W. Huf, S. Wolf and M.S. Zinkernagel.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1111/aos.13157. This DOI is a link to an online electronic document that is either free or for purchase.

**Angiology**

Researchers from Northwestern University Discuss Findings in Angiology (Lack of Association Between Extracranial Carotid and Vertebral Artery Disease and Stroke After Transcatheter Aortic Valve Replacement)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Angiology have been presented. According to news reporting from Chicago, Illinois, by NewsRx journalists, research stated, "Carotid artery stenosis is a risk factor for stroke after surgical aortic valve replacement, but it is unknown whether
carotid and vertebral artery disease impacts the risk of stroke after trans-catheter aortic valve replacement (TAVR). We reviewed 294 consecutive cases of TAVR at a tertiary care medical centre."

The news correspondents obtained a quote from the research from Northwestern University, "Thirty-one patients without preoperative carotid/vertebral duplex ultrasonograms were excluded. Carotid or vertebral artery disease was defined on the basis of >50% stenosis. Outcomes were stroke within 30 days after TAVR, 30-day mortality, and overall survival. Fifty-one patients (19%) had at least 50% stenosis of a carotid or vertebral artery. The carotid and vertebral artery disease group had higher rates of coronary artery disease, previous coronary artery bypass surgery, and peripheral artery disease compared with the control group. Transfemoral access was less common in the carotid and vertebral artery disease group (55% vs 77%; P< 0.01). Stroke occurred in 6.8% of patients (n = 18) within 30 days after TAVR, but no The presence of at least 50% stenosis of a carotid or vertebral artery was not predictive of stroke by logistic regression. There was no difference in 30-day mortality (10% vs 4%; P = 0.11) and overall survival (log-rank test P = 0.84) between the groups. The presence or absence of carotid or vertebral artery stenosis was not significantly related to the occurrence of stroke after TAVR."

According to the news reporters, the research concluded: "Routine screening for carotid and vertebral artery disease before TAVR does not appear justified."

Our news journalists report that additional information may be obtained by contacting J.D. Flaherty, Northwestern University, Feinberg Sch Med, Bluhm Cardiovasc Inst, Chicago, IL 60611, United States. Additional authors for this research include Q.R. Youmans, J.J. Puthumana, R.N. Sweis, M.J. Ricciardi, S.C. Malaisrie, C.J. Davidson and J.D. Flaherty.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1016/j.cjca.2016.03.010. This DOI is a link to an online electronic document that is either free or for purchase.

Heart Disorders and Diseases – Atrial Fibrillation

Researchers from Northwestern University Feinberg School of Medicine Discuss Findings in Atrial Fibrillation [Targeted Anticoagulation for Atrial Fibrillation Guided by Continuous Rhythm Assessment With an Insertable Cardiac Monitor: The Rhythm ...]

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Heart Disorders and Diseases - Atrial
Fibrillation. According to news reporting from Chicago, Illinois, by NewsRx journalists, research stated, "Chronic anticoagulation is recommended for patients with AF and additional stroke risk factors, even during long periods of sinus rhythm. Continuous rhythm assessment with an insertable cardiac monitor (ICM) and use of rapid onset novel oral anticoagulants (NOACs) allow for targeted anticoagulation only around an AF episode, potentially reducing bleeding complications without compromising stroke risk."

Financial support for this research came from NIH.

The news correspondents obtained a quote from the research from the Northwestern University Feinberg School of Medicine, "This multicenter, single-arm study enrolled patients on NOAC with nonpermanent AF and CHADS2 score 1 or 2. After a 60-day run-in with no AF episodes (>=) 1 hour, NOACs were discontinued but reinitiated for 30 days following any AF episode (>=) 1 hour diagnosed through daily ICM transmissions. Major endpoints included time on NOAC, stroke, and bleeding. Among 59 enrollees, 75% were male, age 67 ± 8 years, 76% paroxysmal AF, 69% had prior AF ablation, and mean CHADS2 score 1.3 ± 0.5. Over 466 ± 131 mean days of follow-up there were 24,004 ICM transmissions with a compliance rate of 98.7%. A total of 35 AF episodes (>=) 1 hour occurred in 18 (31%) patients, resulting in a total time on NOAC of 1,472 days. This represents a 94% reduction in the time on NOAC compared to chronic anticoagulation. There were three traumatic bleeds (all on aspirin), three potential transient ischemic attacks (all on aspirin with CHADS2 score of 1), and no strokes or deaths. A targeted strategy of ICM-guided intermittent NOAC administration is feasible."

According to the news reporters, the research concluded: "A large-scale trial is necessary to evaluate the safety of this approach."

Our news journalists report that additional information may be obtained by contacting R. Passman, Northwestern University Feinberg School of Medicine, Chicago, Illinois, United States. Additional authors for this research include P. Leong-Sit, A.C. Andrei, A. Huskin, T.T. Tomson, R. Bernstein, E. Ellis, J.W. Waks and P. Zimetbaum.

Researchers from Northwestern University Report Details of New Studies and Findings in the Area of Gliomas (Mutant IDH1 and thrombosis in gliomas)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Oncology - Gliomas are discussed in a new report. According to news reporting originating in Chicago, Illinois, by NewsRx journalists, research stated, "Mutant isocitrate dehydrogenase 1 (IDH1) is common in gliomas, and produces D-2-hydroxyglutarate (D-2-HG). The full effects of IDH1 mutations on glioma biology and tumor microenvironment are unknown."

Funders for this research include National Cancer Institute, Friedberg Charitable Foundation.

The news reporters obtained a quote from the research from Northwestern University, "We analyzed a discovery cohort of 169 World Health Organization (WHO) grade II-IV gliomas, followed by a validation cohort of 148 cases, for IDH1 mutations, intratumoral microthrombi, and venous thromboemboli (VTE). 430 gliomas from The Cancer Genome Atlas were analyzed for mRNAs associated with coagulation, and 95 gliomas in a tissue microarray were assessed for tissue factor (TF) protein. In vitro and in vivo assays evaluated platelet aggregation and clotting time in the presence of mutant IDH1 or D-2-HG. VTE occurred in 26-30% of patients with wild-type IDH1 gliomas, but not in patients with mutant IDH1 gliomas (0%). IDH1 mutation status was the most powerful predictive marker for VTE, independent of variables such as GBM diagnosis and prolonged hospital stay. Microthrombi were far less common within mutant IDH1 gliomas regardless of WHO grade (85-90% in wild-type versus 2-6% in mutant), and were an independent predictor of IDH1 wild-type status. Among all 35 coagulation-associated genes, F3 mRNA, encoding TF, showed the strongest inverse relationship with IDH1 mutations. Mutant IDH1 gliomas had F3 gene promoter hypermethylation, with lower TF protein expression. D-2-HG rapidly inhibited platelet aggregation and blood clotting via a novel calcium-dependent, methylation-independent mechanism. Mutant IDH1 glioma engraftment in mice significantly prolonged bleeding time. Our data suggest that mutant IDH1 has potent antithrombotic activity within gliomas and throughout the peripheral circulation."

According to the news reporters, the research concluded: "These findings have implications for the pathologic evaluation of gliomas, the effect of altered isocitrate metabolism on tumor microenvironment, and risk assessment of glioma patients for VTE."

Our news correspondents report that additional information may be obtained by contacting C. Horbinski, Northwestern University, Dept. of Pathol, Chicago, IL 60611, United States. Additional authors for this research include S.R. Schwarze, L. Khoury, C. Thomas, M.J. Wu, L. Chen, R. Chen, Y.X. Liu, M.A. Schwartz, C. Amidei, P. Kumthekar, C.G. Benjamin, K. Song, C. Dawson, J.M. Rispoli, G. Fatterpekar, J.G. Golfinos, D. Kondziolka, M. Karajannis and P.

Researchers from Northwestern University Report Findings in Andersen-Tawil Syndrome (Novel calmodulin mutations associated with congenital long QT syndrome affect calcium current in human cardiomyocytes)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Heart Disorders and Diseases - Andersen-Tawil Syndrome have been presented. According to news reporting originating from Chicago, Illinois, by NewsRx correspondents, research stated, "Calmodulin (CaM) mutations are associated with cardiac arrhythmia susceptibility including congenital long QT syndrome (LQTS). The purpose of this study was to determine the clinical, genetic, and functional features of 2 novel CaM mutations in children with life-threatening ventricular arrhythmias."

Our news editors obtained a quote from the research from Northwestern University, "The clinical and genetic features of 2 congenital arrhythmia cases associated with 2 novel CaM gene mutations were ascertained. Biochemical and functional investigations were conducted on the 2 mutations. A novel de novo CALM2 mutation (D132H) was discovered by candidate gene screening in a male infant with prenatal bradycardia born to healthy parents. Postnatal course was complicated by profound bradycardia, prolonged corrected QT interval (651 ms), 2:1 atrioventricular block, and cardiogenic shock. He was resuscitated and was treated with a cardiac device. A second novel de novo mutation in CALM1 (D132V) was discovered by clinical exome sequencing in a 3-year-old boy who suffered a witnessed cardiac arrest secondary to resuscitation revealed a prolonged corrected QT interval of 574 ms. The Ca2+ affinity of CaM-D132H and CaM-D132V revealed extremely weak binding to the C-terminal domain, with significant structural perturbations noted for D132H. Voltage-damp recordings of human induced pluripotent stem cell-derived cardiomyocytes transiently expressing wild-type or mutant CaM demonstrated that both mutations caused impaired Ca2+-dependent inactivation of voltage-gated Ca2+ current. Neither mutant affected voltage-dependent inactivation. Our findings implicate impaired Ca2+-dependent inactivation in human cardiomyocytes as the plausible mechanism for long QT syndrome associated with 2 novel CaM mutations."

According to the news editors, the research concluded: "The data further expand the spectrum of genotype and phenotype associated with calmodulinopathy."

The news editors report that additional information may be obtained by contacting A.L. George, Northwestern University, Dept. of Pharmacol, Feinberg Sch Med, Chicago, IL 60611, United States. Oncology - Liver Cancer

Researchers from Northwestern University Report Findings in Liver Cancer (Current Guidelines for the Diagnosis and Management of Hepatocellular Carcinoma: A Comparative Review)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Oncology - Liver Cancer have been published. According to news reporting originating from Chicago, Illinois, by NewsRx correspondents, research stated, "The purpose of this article is to review aspects of guidelines pertinent to radiologists involved in the diagnosis or treatment of hepatocellular carcinoma."

Our news editors obtained a quote from the research from Northwestern University, "Early diagnosis and treatment of hepatocellular carcinoma are important because only 10% of patients meet the criteria for curative therapy at the time of diagnosis. Several organizations have developed guidelines for screening, diagnosis, and treatment of hepatocellular carcinoma."

According to the news editors, the research concluded: "Radiologists play a pivotal role in every aspect of these guidelines."

For more information on this research see: Current Guidelines for the Diagnosis and Management of Hepatocellular Carcinoma: A Comparative Review. American Journal of Roentgenology, 2016;207(5):W88-W98. American Journal of Roentgenology can be contacted at: Amer Roentgen Ray Soc, 1891 Preston White Dr, Subscription Fulfillment, Reston, VA 22091, USA.

Researchers from Ohio State University Discuss Findings in Acinetobacter baumannii (Correlation of Checkerboard Synergy Testing with Time-Kill Analysis and Clinical Outcomes of Extensively Drug-Resistant Acinetobacter baumannii Respiratory Infections)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Gram-Negative Bacteria - Acinetobacter baumannii are discussed in a new report. According to news reporting originating from Columbus, Ohio, by NewsRx correspondents, research stated, "We tested 76 extensively drug-resistant (XDR) Acinetobacter baumannii isolates by the checkerboard method using only wells containing serum-achievable concentrations (SACs) of drugs. Checkerboard results were correlated by time-kill assay and clinical outcomes."

Our news editors obtained a quote from the research from Ohio State University, "Minocycline-colistin was the best combination in vitro, as it inhibited growth in one or more SAC wells in all isolates. Patients who received a combination that inhibited growth in one or more SAC wells demonstrated better microbiological clearance than those who did not (88% versus 30%; P = 0.025)."

According to the news editors, the research concluded: "The checkerboard platform may have clinical utility for XDR A. baumannii infections."

The news editors report that additional information may be obtained by contacting J.M. Balada-Llasat, Ohio State University, Medical Center, Dept. of Pathol, Columbus, OH 43210, United States. Additional authors for this research include K.A. Bauer, S.M. Pouch, K. Thomas, D. Smith, D.A. Goff, P. Pancholi and J.M. Balada-Llasat.

Researchers from Oregon Health and Science University Report Findings in Physiology (SPAK and OSR1 play essential roles in potassium homeostasis through actions on the distal convoluted tubule)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Life Science Research - Physiology. According to news reporting originating from Portland, Oregon, by NewsRx correspondents, research stated, "STE20 (Sterile 20)/SPS-1 related proline/alanine-rich kinase (SPAK) and oxidative stress-response kinase-1 (OSR1) activate the renal cation cotransporters Na+-K+-2Cl(-) cotransporter (NKCC2) and Na+-Cl- cotransporter (NCC) via phosphorylation. Knockout mouse models suggest that OSR1 mainly activates NKCC2, while SPAK mainly activates NCC, with possible cross-compensation."

Our news editors obtained a quote from the research from Oregon Health and Science University, "We tested the hypothesis that disrupting both kinases causes severe polyuria and salt-wasting by generating SPAK/OSR1 double knockout (DKO) mice. DKO mice displayed lower systolic blood pressure compared with SPAK knockout (SPAK-KO) mice, but displayed no severe phenotype even after dietary salt restriction. Phosphorylation of NKCC2 at SPAK/OSR1-dependent sites was lower than in SPAK-KO mice, but still significantly greater than in wild type mice. In the renal medulla, there was significant phosphorylation of NKCC2 at SPAK/OSR1-dependent sites despite a complete absence of SPAK and OSR1, suggesting the existence of an alternative activating kinase. The distal convoluted tubule has been proposed to sense plasma [K+], with NCC activation serving as the primary effector pathway that modulates K+ secretion, by metering sodium delivery to the collecting duct. Abundance of phosphorylated NCC (pNCC) is dramatically lower in SPAK-KO mice than in wild type mice, and the additional disruption of OSR1 further reduced pNCC. SPAK-KO and kidney-specific OSR1 single knockout mice maintained plasma [K+] following dietary potassium restriction, but DKO mice developed severe hypokalaemia. Unlike mice lacking SPAK or OSR1 alone, DKO mice displayed an inability to phosphorylate NCC under these conditions."

According to the news editors, the research concluded: "These data suggest that SPAK and OSR1 are essential components of the effector pathway that maintains plasma [K+]."

The news editors report that additional information may be obtained by contacting J.A. McCormick, Oregon Health Sciences University, Div Nephrol & Hypertens, Dept. of Med, Portland, OR 97239, United States. Additional authors for this research include K.W. Barber, K.I. Lopez-Cayuqueo, A.S. Terker, E.R. Argaiz, B.M. Gassaway, R. Chambrey, G. Gamba, J. Rinehart and J.A. McCormick.

Researchers from Osaka Medical College Describe Findings in Liver Cancer (Rosuvastatin as a potential preventive drug for the development of hepatocellular carcinoma associated with non-alcoholic fatty liver disease in mice)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Oncology - Liver Cancer have been published. According to news reporting out of Takatsuki, Japan, by NewsRx editors, research stated, "Hepatocellular carcinoma (HCC) represents approximately 85% of all primary liver cancer cases. Non-alcoholic fatty liver disease (NAFLD) is one of the risk factors for HCC."

Our news journalists obtained a quote from the research from Osaka Medical College, "NAFLD occurs in patients with components of metabolic syndrome, such as type 2 diabetes mellitus, obesity, hypertension and hyperlipidemia. Therefore, hyperlipidemia also represents a patient population at risk for HCC that can readily be identified. Rosuvastatin, a 3-hydroxy-3-methyl-glutaryl coenzyme A (HMG-CoA) reductase inhibitor, has exhibited a more potent affinity for the active site of HMG-CoA reductase than other statins. In addition, the hepatic uptake of rosuvastatin in rats has been found to be more selective and efficient than that with other drugs. Furthermore, the cytoprotective effects of rosuvastatin against ischemic injury have been clearly reported. Thus, in this study, we aimed to determine the role of rosuvastatin as a preventive drug in HCC associated with NAFLD. STAM mice, which developed HCC from NAFLD by being fed a high-fat diet (HFD), were divided into a group in which a HFD was given to the mice for 15 weeks (n=8) and another in which a HFD supplemented with 0.00125% rosuvastatin was given to the mice for 15 weeks (n=8). Rosuvastatin inhibited the development of hepatic tumors in the mice with NAFLD induced by a specific diet both macroscopically and histologically. Rosuvastatin significantly decreased the expression levels of pro-inflammatory cytokines, such as tumor necrosis factor (TNF)-, interleukin (IL)-6 and transforming growth factor (TGF)-1. Tumor aggressiveness is mediated by angiogenic factors. Therefore, we examined the hepatic mRNA expression of vascular endothelial growth factor receptor (VEGFR), epidermal growth factor receptor (EGFR) and platelet-derived growth factor (PDGF). The hepatic expression of these factors significantly decreased in the rosuvastatin-fed mice. Our results thus suggest rosuvastatin that prevents carcinogenesis and improves the hepatic background."

According to the news editors, the research concluded: "Our data suggest that rosuvastatin has potential for use as a preventive drug for the development of HCC associated with NAFLD in mice."

For more information on this research see: Rosuvastatin as a potential preventive drug for the development of hepatocellular carcinoma associated with non-alcoholic fatty liver disease in mice. International Journal of Molecular Medicine, 2016;38(5):1499-1506. International Journal of Molecular Medicine can be contacted at: Spandidos Publ Ltd, Pob 18179, Athens, 116 10, Greece.

Our news journalists report that additional information may be obtained by contacting S. Fukunishi, Osaka Medical College, Dept. of Internal Med 2, Takatsuki, Osaka 5698686, Japan. Researchers from Osaka University Graduate School of Medicine Describe Findings in Therapeutics (Predictors of Survival in Patients With FIGO Stage IVB Cervical Cancer)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Therapeutics. According to news originating from Osaka, Japan, by NewsRx correspondents, research stated, "The aim of this study was to identify prognostic factors and establish a model for predicting life expectancy in International Federation of Gynecology and Obstetrics stage IVB cervical cancer patients. The baseline characteristics and outcome data of patients with stage IVB cervical cancer between May 1994 and October 2014 were collected and retrospectively reviewed."

Our news journalists obtained a quote from the research from the Osaka University Graduate School of Medicine, "A Cox proportional hazards regression model was used to identify independent predictors of survival in stage IVB cervical cancer patients. A total of 107 patients were included in our database. The median overall survival (OS) period was 16 months. Multivariate analysis revealed that the metastatic site (hazards ratio, 3.09; 95% confidence interval, 1.94-4.88; p<0.0001) and a white blood cell (WBC) count exceeding 10,000/mL (hazards ratio, 2.02; 95% confidence interval, 1.19-3.30; p=0.0102) were significant prognostic factors in terms of OS. Patient survival was inversely correlated with the number of these prognostic factors possessed. When the patients were divided into 3 prognostic groups, the median OS of the patients with 0, 1, or 2 poor prognostic factors was 26, 12, and 7 months, respectively. Among the patients with WBC counts of less than 10,000/mL, treatment with radiotherapy resulted in improved survival compared with chemotherapy or palliative care alone. In contrast, radiotherapy had minimal effects on survival in patients with WBC counts of greater than 10,000/mL. The metastatic site and an elevated WBC count are significant prognostic factors in patients with stage IVB cervical cancer."

According to the news editors, the research concluded: "Our prognostic model composed of these 2 clinical variables might enable physicians to predict survival more accurately."

The news correspondents report that additional information may be obtained from T. Sasano, Departments of *Obstetrics and Gynecology and †Radiation Oncology, Osaka University Graduate School of Medicine, Osaka, Japan. Additional authors for this research include S. Mabuchi, H. Kuroda, R. Takahashi, K. Kozasa, F. Isohashi, Y. Yoshioka, K. Ogawa.

Oncology - Colon Cancer

Researchers from Osaka University Report New Studies and Findings in the Area of Colon Cancer (Metabolic Adaptation to Nutritional Stress in Human Colorectal Cancer)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Oncology - Colon Cancer are presented in a new report. According to news reporting out of Osaka, Japan, by NewsRx editors, research stated, "Tumor cells respond to their microenvironment, which can include hypoxia and malnutrition, and adapt their metabolism to survive and grow. Some oncogenes are associated with cancer metabolism via regulation of the related enzymes or transporters."

Our news journalists obtained a quote from the research from Osaka University, "However, the importance of metabolism and precise metabolic effects of oncogenes in colorectal cancer remain unclear. We found that colorectal cancer cells survived under the condition of glucose depletion, and their resistance to such conditions depended on genomic alterations rather than on KRAS mutation alone. Metabolomic analysis demonstrated that those cells maintained tricarboxylic acid cycle activity and ATP production under such conditions. Furthermore, we identified pivotal roles of GLUD1 and SLC25A13 in nutritional stress. GLUD1 and SLC25A13 were associated with tumor aggressiveness and poorer prognosis of colorectal cancer."

According to the news editors, the research concluded: "GLUD1 and SLC25A13 may serve as new targets in treating refractory colorectal cancer which survive in malnourishment microenvironments."

For more information on this research see: Metabolic Adaptation to Nutritional Stress in Human Colorectal Cancer. Scientific Reports, 2016;6():1-13. Scientific Reports can be contacted at: Nature Publishing Group, Macmillan Building, 4 Crinan St, London N1 9XW, England. Researchers from Otto-von-Guericke-University Report Recent Findings in Myotomy [Jackhammer esophagus: high-resolution manometry and therapeutic approach using peroral endoscopic myotomy (POEM)]

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Surgery - Myotomy are discussed in a new report. According to news reporting from Magdeburg, Germany, by NewsRx journalists, research stated, "We present the first report on peroral endoscopic myotomy (POEM) in the treatment of jackhammer esophagus. A 34-year-old female patient was newly diagnosed with a jackhammer esophagus."

The news correspondents obtained a quote from the research from Otto-von-Guericke-University, "After failure of medical treatment, the patient underwent POEM procedure for myotomy of the spastic segment. Postoperatively, a mild emphysema and pneumothorax occurred that required drainage and antibiotic therapy until full recovery. Discharge was possible after 5 days. Six months later, she presented with recurrent but mild pain due to a remnant spastic segment proximal to the myotomy."

According to the news reporters, the research concluded: "Endoscopic balloon dilation was performed twice within 6 weeks with full symptomatic relief of pain and mild symptoms of dysphagia."

Our news journalists report that additional information may be obtained by contacting A. Kandulski, Otto von Guericke Univ, Dept. of Gastroenterol Hepatol & Infect Dis, Magdeburg, Germany. Additional authors for this research include K.H. Fuchs, J. Weigt and P. Malfertheiner.

Cardiology

Researchers from PRESTO Report Findings in Cardiology (TRPC3-GEF-H1 axis mediates pressure overload-induced cardiac fibrosis)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Cardiology. According to news reporting from Saitama, Japan, by NewsRx journalists, research stated, "Structural cardiac
remodeling, accompanying cytoskeletal reorganization of cardiac cells, is a major clinical outcome of diastolic heart failure. A highly local Ca2+ influx across the plasma membrane has been suggested to code signals to induce Rho GTPase-mediated fibrosis, but it is obscure how the heart specifically decodes the local Ca2+ influx as a cytoskeletal reorganizing signal under the conditions of the rhythmic Ca2+ handling required for pump function.”

The news correspondents obtained a quote from the research from PRESTO, "We found that an inhibition of transient receptor potential canonical 3 (TRPC3) channel activity exhibited resistance to Rho-mediated maladaptive fibrosis in pressure-overloaded mouse hearts. Proteomic analysis revealed that microtubule-associated Rho guanine nucleotide exchange factor, GEF-H1, participates in TRPC3-mediated RhoA activation induced by mechanical stress in cardiomyocytes and transforming growth factor (TGF)beta stimulation in cardiac fibroblasts. We previously revealed that TRPC3 functionally interacts with microtubule-associated NADPH oxidase (Nox) 2, and inhibition of Nox2 attenuated mechanical stretch-induced GEF-H1 activation in cardiomyocytes. Finally, pharmacological TRPC3 inhibition significantly suppressed fibrotic responses in human cardiomyocytes and cardiac fibroblasts."

According to the news reporters, the research concluded: "These results strongly suggest that microtubule-localized TRPC3-GEF-H1 axis mediates fibrotic responses commonly in cardiac myocytes and fibroblasts induced by physico-chemical stimulation."

For more information on this research see: TRPC3-GEF-H1 axis mediates pressure overload-induced cardiac fibrosis. Scientific Reports, 2016;6():1-12. Scientific Reports can be contacted at: Nature Publishing Group, Macmillan Building, 4 Crinan St, London N1 9XW, England. (Nature Publishing Group - www.nature.com/; Scientific Reports - www.nature.com/srep/)

Our news journalists report that additional information may be obtained by contacting M. Nishida, JST, PRESTO, Kawaguchi, Saitama 3320012, Japan. Additional authors for this research include N. Our news journalists obtained a quote from the research from Peking Union Medical College, "In this study, HeLa cells were used as a testing model for the treatment of IFN-alpha on cervical cancer. The results indicate that IFN-alpha markedly inhibits the proliferation and induces the apoptosis of HeLa cells. The activation of caspase 3, the up-regulation of both Bim and cleaved poly (ADP-ribose) polymerase (PARP) 1, the down-regulation of Bcl-xL, as well as the release of cytochrome c from mitochondria were significantly induced upon IFN-alpha treatment, indicating that the intrinsic apoptotic pathway could be activated by IFN-alpha treatment. In addition, caspase 4-which is involved in the endoplasmic reticulum (ER) stress-induced apoptosis-was activated in response to IFN-alpha treatment. Knocking down caspase 4 by small interfering RNA (siRNA) markedly reduced the IFN-alpha-mediated cell apoptosis. However, no significant changes in the expressions of caspases 8 and 10 were observed upon IFN-alpha treatment, indicating that the apoptosis caused by IFN-alpha might be independent of the extrinsic apoptotic pathway."

According to the news editors, the research concluded: "These findings suggest that IFN-alpha may possess anti-cervical cancer capacity by activating cell apoptosis via the intrinsic mitochondrial pathway and caspase-4-related ER stress-induced pathway."

For more information on this research see: Interferon alpha Induces the Apoptosis of Cervical Cancer HeLa Cells by Activating both the Intrinsic Mitochondrial Pathway and Endoplasmic Reticulum Stress-Induced Pathway. International Journal of Molecular Sciences, 2016;17(11):1101-1113. International Journal of Molecular Sciences can be contacted at: Mdp Ag, St Alban-Anlage 66, Ch-4052 Basel, Switzerland.

Our news journalists obtained a quote from the research from Peking Union Medical College, "Patients presenting with acute flares were asked about common triggers before the flare. 'Early-onset' gout was defined as onset of gout before 40 years and 'late-onset' as onset >= 40 years. Major joint involvement, flare frequency before presentation, the cumulative number of involved joints, proportions of tophi complications at presentation, flare triggers, as well as any metabolic, cardiovascular, cerebrovascular, and renal comorbidities, were compared between the 2 groups. A total of 778 gout patients were enrolled in this study, including 449 (57.7%) in the early-onset group and 329 (42.3%) in the late-onset group. Compared with the late-onset gout patients, the early-onset gout patients had a higher proportion of ankle/mid-foot involvement (62.8% vs 48.2%, P<0.001), more frequent flares before presentation (11.2 +/- 1.17 vs 6.97 +/- 1.03 times per year, P=0.01), higher cumulative number of involved joints (5.2 +/- 0.26 vs 3.8 +/- 0.26, P<0.001), and more likely to have alcohol consumption as a flare trigger (65.2% vs 53.9%, P=0.03); whereas early-onset gout patients had fewer metabolic, cardiovascular, cerebrovascular, or renal complications. Early-and late-onset gout patients had different clinical features.

According to the news editors, the research concluded: "Early-onset seems to be influenced more by lifestyle, while late-onset patients have more complications because of comorbidities."

For more information on this research see: Clinical characteristics of early- and late-onset gout. A cross-sectional observational study from a Chinese gout clinic. Medicine, 2016;95 (47):191-196. Oncology - Rectal Cancer

Researchers from Peking Union Medical College Report Recent Findings in Rectal Cancer (Interim analysis of postoperative chemoradiotherapy with capecitabine and oxaliplatin versus capecitabine alone for pathological stage II and III rectal ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Oncology - Rectal Cancer is now available. According to news reporting originating in Beijing, People's Republic of China, by NewsRx journalists, research stated. "The aim of this study is to present an interim analysis of a phase III trial (NCT00714077) of postoperative concurrent capecitabine and radiotherapy with or without..."
oxaliplatin for pathological stage II and III rectal cancer. Patients with pathologically confirmed stage II and III rectal cancer were randomized to either radiotherapy with concurrent capecitabine (Cap-RT group) or with capecitabine and oxaliplatin (Capox-RT group).

The news reporters obtained a quote from the research from Peking Union Medical College, "The primary endpoint was 3-year disease-free survival rate (DFS). The 3-year DFS rate was 73.9% in the Capox-RT group and 71.6% in the Cap-RT group (HR 0.92, p=0.647), respectively. No significant difference was observed in overall survival, cumulative incidence of local recurrence and distant metastasis between the two groups (p >0.05). More grade 3-4 acute toxicity was observed in the Capox-RT group than in the Cap-RT group (38.1% vs. 29.2%, p= 0.041)."

According to the news reporters, the research concluded: "Inclusion of oxaliplatin in the capecitabine-based postoperative regimen did not improve DFS but increased toxicities for pathological stage II and III rectal cancer in this interim analysis."

For more information on this research see: Interim analysis of postoperative chemoradiotherapy with capecitabine and oxaliplatin versus capecitabine alone for pathological stage II and III rectal cancer: a randomized multicenter phase III trial. Oncotarget, 2016;7 (18):25576-84.

Inflammation

Researchers from Peking University Detail New Studies and Findings in the Area of Inflammation [Intermedin(1-53) Protects Against Myocardial Fibrosis by Inhibiting Endoplasmic Reticulum Stress and Inflammation Induced by Homocysteine in ...]

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Inflammation. According to news reporting originating in Beijing, People's Republic of China, by NewsRx journalists, research stated, "Endoplasmic reticulum stress (ERS) and inflammation participate in cardiac fibrosis. Importantly, a novel paracrine/autocrine peptide intermedin(1-53) (IMD1-53) in the heart inhibits myocardial fibrosis in rats."

The news reporters obtained a quote from the research from Peking University, "However, the mechanisms are yet to be fully elucidated. Myocardial fibrosis in apolipoprotein
E-deficient (ApoE(-/-)) mice and neonatal rat cardiac fibroblasts (CFs) were induced using homocysteine (Hcy). IMD1-53 inhibited myocardial fibrosis in vivo and in vitro. Picrosirius red staining showed that IMD1-53 reduced myocardial interstitial collagen deposition in ApoE(-/-) mice treated with Hcy and decreased the expression of myocardial collagen I and III, which was further verified in rat CFs. IMD1-53 attenuated myocardial hypertrophy, as shown by cardiomyocyte cross-sectional area, ratio of heart weight to body weight, and mRNA levels of atrial natriuretic peptide and brain natriuretic peptide. IMD1-53 inhibited the upregulation of ERS hallmarks such as glucose-regulated protein 78 (GRP78), GRP94, activating transcription factor 6 (ATF6), ATF4, inositol-requiring enzyme 1 alpha, spliced-X-box-binding protein-1, protein kinase receptor-like ER kinase, and eukaryotic translation initiation factor 2 alpha in mouse myocardium and rat CFs treated with Hcy. In addition, IMD1-53 decreased the production of inflammatory factors such as tumor necrosis factor-alpha, monocyte chemotactic protein-1, interleukin-6 (IL-6), and IL-1 beta in the mouse myocardium and rat CFs treated with Hcy. Concurrently, IMD1-53 ameliorated the expression of nuclear factor-kappa B, transforming growth factor-beta 1, and c-Jun N-terminal kinase in the mouse myocardium and rat CFs treated with Hcy.

According to the news reporters, the research concluded: "IMD potentially protects against myocardial fibrosis induced by Hcy in ApoE(-/-) mice, possibly via attenuating myocardial ERS and inflammation."

**Oncology - Anaplastic Large Cell Lymphoma**

**Researchers from Peking University Provide Details of New Studies and Findings in the Area of Anaplastic Large Cell Lymphoma (Primary central nervous system ALK-positive anaplastic large cell lymphoma in an adult A rare case report)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Oncology - Anaplastic Large Cell Lymphoma. According to news reporting out of Beijing, People's Republic of China, by NewsRx editors, research stated, "Anaplastic large cell lymphoma (ALCL) is an aggressive non-
Hodgkin lymphoma. It mostly invades lymph nodes with extranodal involvement observed in the soft tissue, bone, and skin."

Our news journalists obtained a quote from the research from Peking University, "Patient concerns: We report a 34-year-old Chinese male patient who presented with headache, diplopia, and vomit. Cerebrospinal fluid (CSF) analysis via lumbar puncture showed elevated CSF pressure, elevated CSF protein concentrations, decreased CSF glucose and chloride concentration significantly, and pleocytosis of 68 to 350 x 10(6)/L, in which lymphocytes and monocytes were predominant. These changes could be suggestive of tuberculous (TB) meningitis. Enhanced magnetic resonance imaging of spinal cord delineated multiple enhancing nodules in spinal cord, cauda equina, and crista membrane, and multiple abnormal enhancing lesions in bilateral lumbar intervertebral foramen. Diagnoses: Spinal dura mater biopsy and paraffin pathology examination revealed anaplastic lymphoma kinase positive ALCL. High-dose methotrexate, cytosine arabinoside craniospinal, and radiotherapy. Last follow-up on September 22, 2015 showed no evidence of tumor recurrence and the lower extremity muscle strength recovered to 4/5. Lessons: ALCL of primary central nervous system is an exceedingly rare tumor, which is usually misdiagnosed as meningitis (especially TB meningitis) according to clinical manifestation and laboratory examination."

According to the news editors, the research concluded: "Thus closely monitoring patient's conditions and timely adjusting therapeutic regimen during treatment are necessary."

For more information on this research see: Primary central nervous system ALK-positive anaplastic large cell lymphoma in an adult A rare case report. Medicine, 2016;95 (49):318-323. Amyotrophic Lateral Sclerosis

Researchers from Peking University Third Hospital Detail Findings in Amyotrophic Lateral Sclerosis (Single-nucleotide Polymorphism rs2275294 in ZNF512B is not Associated with Susceptibility to Amyotrophic Lateral Sclerosis in a Large Chinese ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Amyotrophic Lateral Sclerosis. According to news reporting out of Beijing, People's Republic of China, by NewsRx editors, research stated, "Amyotrophic lateral sclerosis (ALS) is a fatal neurodegenerative disease that
Our news journalists obtained a quote from the research from Peking University Third Hospital, "Here, we performed a case-control study examining the possible association of rs2275294 with risk of sporadic ALS (SALS) in a large Chinese cohort. To assess this association, we performed a replication study in 953 SALS patients and 1039 age-and gender-matched healthy control subjects, who were recruited from Peking University Third Hospital and the First Affiliated Hospital of Anhui Medical University from January 2004 to December 2013 throughout China. We genotyped the rs2275294 SNP using polymerase chain reaction and direct sequencing. The allele frequency of rs2275294 in ZNF512B was different between Japanese and Chinese. The association in Chinese between ALS patients and controls did not reach statistical significance (p=0.54; odds ratio=0.94; 95% confidence interval=0.76-1.15). The SNP rs2275294 in ZNF512B is not considered to be associated with ALS susceptibility in the Chinese population. Our study highlights genetic heterogeneity in ALS susceptibility in different population."

According to the news editors, the research concluded: "Given our negative results, further replication study involving larger and more homogeneous samples in different ethnicities should be performed in the future."

Our news journalists report that additional information may be obtained by contacting M. Deng, Medical Research Center, Peking University Third Hospital, Beijing 100191, People's Republic of China. Additional authors for this research include T. Liu, J. Chen, X.G. Li, X.X. Liu, W.C. Liu, K. Wang and M. Deng.

Recreational and Healthcare Contexts, Food ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Nutritional and Metabolic Diseases and Conditions - Obesity have been published. According to news originating from Baton Rouge, Louisiana, by NewsRx correspondents, research stated, "To examine change in county-level adult obesity prevalence between 2004 and 2009 and identify associated community characteristics. Change in county-level adult (>=20 years) obesity prevalence was calculated for a 5-year period (2004-2009)."

Our news journalists obtained a quote from the research from Pennington Biomedical Research Center, "Community measures of economic, healthcare, recreational, food environment, population structure, and education contexts were also calculated. Regression analysis was used to assess community characteristics associated (p <0.01) with change in adult obesity prevalence. Mean?SD change in obesity prevalence was 5.1?2.4%. Obesity prevalence decreased in 1.4% (n=44) and increased in 98% (n=3,060) of counties from 2004-2009. Results showed that both baseline levels and increases in physically inactive adults were associated with greater increases in obesity prevalence, while baseline levels of and increases in physician density and grocery store/supercenter density were related to smaller increases in obesity rates. Baseline levels of the Hispanic population share were negatively linked to changing obesity levels, while places with greater Hispanic population growth saw greater increases in obesity. Most counties in the U.S. experienced increases in adult obesity prevalence from 2004 to 2009."

According to the news editors, the research concluded: "Findings suggest that community-based interventions targeting adult obesity need to incorporate a range of community factors, such as levels of physical inactivity, access to physicians, availability of food outlets, and ethnic/racial population composition."

For more information on this research see: Change in Obesity Prevalence across the United States Is Influenced by Recreational and Healthcare Contexts, Food Environments, and Hispanic Populations. Plos One, 2016;11(2):e0148394. (Public Library of Science - www.plos.org; Plos One - www.plosone.org)

The news correspondents report that additional information may be obtained from C.A. Myers, Pennington Biomedical Research Center, Baton Rouge, Louisiana, 70808, United States. Additional authors for this research include T. Slack, C.K. Martin, S.T. Broyles and S.B Heymsfield.

Oncology - Squamous Cell Carcinoma

Researchers from People's Hospital Describe Findings in Squamous Cell Carcinoma (Association of genetic polymorphisms in PTEN and additional gene-gene interaction with risk of esophageal squamous cell
carcinoma in Chinese Han population)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Oncology - Squamous Cell Carcinoma. According to news reporting originating from Jiangsu, People's Republic of China, by NewsRx correspondents, research stated, "This study aims to investigate the association of five single nucleotide polymorphisms (SNPs) in the phosphatase and tensin homologue (PTEN) gene and additional role of gene-gene interaction with esophageal squamous cell carcinoma (ESCC), based on a Chinese case-control study. A total of 871 subjects (420 males and 451 females) were selected, including 425 ESCC cases and 446 controls."

Our news editors obtained a quote from the research from People's Hospital, "Five SNPs were selected for genotyping in the case-control study: rs2735343, rs555895, rs2299939, rs17433184 and rs701848. Logistic regression model was used to examine the association between five SNP and ESCC, and additional interaction among five SNP, odds ratio (OR) and 95% confident interval (95%CI) were calculated. All genotypes were distributed according to Hardy-Weinberg equilibrium in controls. The carriers of homozygous mutant of rs2735343 and rs701848 polymorphism revealed increased ESCC risk than those with wild-type homozygotes, and OR (95%CI) were 1.27 (1.09-2.08) and 1.45 (1.17-1.98), respectively. We also found a potential gene-gene interaction between rs2735343 and rs701848 (P = 0.0010), and a potential gene-gene interaction among all five SNP (P = 0.0107) after covariates adjustment. Subjects with TC or CC of rs2735343 and TC or CC of rs701848 genotype have highest ESCC risk, compared to subjects with TT of rs2735343 and TT of rs701848 genotype, OR (95% CI) was 2.76 (1.37-3.45) after covariates adjustment. The carriers of homozygous mutant of rs2735343 and rs701848 polymorphism revealed increased ESCC risk."

According to the news editors, the research concluded: "We also found a potential gene-gene interaction between rs2735343 and rs701848 and a potential gene-gene interaction among all five SNPs."

The news editors report that additional information may be obtained by contacting X. Xu, Yixing Peoples Hosp, Dept. of Gastroenterol, Wuxi 214200, Jiangsu, People's Republic of China. Additional authors for this research include G. Chen, L. Wu and L. Liu.

Keywords for this news article include: Jiangsu, People's Republic of China, Asia, Squamous Cell Carcinoma, Carcinomas, Oncology, Genetics, People's Hospital.

Investigators discuss new findings in Drugs and Therapies - Antiretrovirals. According to news originating from Guilin, People's Republic of China, by NewsRx correspondents, research stated, "The study aimed to clarify whether the rtI233V substitution affects adefovir (ADV) resistance. A total of 18,419 patients from Beijing 302 Hospital were investigated."

Our news journalists obtained a quote from the research from People's Hospital, "HBV complete reverse transcriptase region of the polymerase was screened by direct sequencing and verified by clonal sequencing if necessary. Replication-competent wild-type and mutant HBV genomic amplicons were transfected into HepG2 cells for phenotypic analysis of viral replication capacity and drug susceptibility. The rtI233V substitution was detected in 38/5,344 (0.71%) ADV-treated patients and in 8/13,075 patients without receiving ADV (P <0.001). Eight patients with rtI233V +/- rtA181V/rt N236T had virological break-through in the clinical course of ADV treatment. Phenotypic analysis showed that rtI233V mutants from patient 1 and patient 2 exhibited 1.57-fold and 1.51-fold decreased susceptibility to ADV, respectively, compared to wild-type virus; by contrast, rtN236T and rtI233V+N236T mutants from patient 1 had 6.82-fold and 5.28-fold decreased susceptibility to ADV. rtI233V, rtN236T and rtI233V+ N236T mutants had 97.5%, 30.2% and 69.7% of replication capacity compared to wild-type virus in the absence of antivirals and all remained susceptible to lamivudine, entecavir and tenofovir. Viral replication capacity correspondingly decreased after eliminating rtI233V from rtI233V+ N236T mutant and was restored after introducing rtI233V into rtN236T mutant. In clinical practice, switching to entecavir rescue therapy suppressed HBV DNA to an undetectable level for both patients."

According to the news editors, the research concluded: "RtI233V usually emerged in ADV-treated patients with little impact on ADV susceptibility but it effectively restored replication capacity of the rtN236T mutant, suggesting that rtI233V may partly serve as a compensatory mutation associated with ADV resistance."

The news correspondents report that additional information may be obtained from S.Q. Cheng, Third Peoples Hosp Guilin, Dept. of Liver Dis, Guilin, People's Republic of China. Additional authors for this research include S.J. Xin, X.L. Ye, R.J. Chen, Z.H. Xu, X.D. Li, H.Y. Ye, S.Q. Cheng and D.P. Xu.

Researchers from Pfizer Report New Studies and Findings in the Area of Pharmacoepidemiology (Recommendations for benefit-risk assessment methodologies and visual representations)
2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Drugs and Therapies - Pharmacoepidemiology are presented in a new report. According to news reporting from New York City, New York, by NewsRx journalists, research stated, "The purpose of this study is to draw on the practical experience from the PROTECT BR case studies and make recommendations regarding the application of a number of methodologies and visual representations for benefit-risk assessment. Eight case studies based on the benefit-risk balance of real medicines were used to test various methodologies that had been identified from the literature as having potential applications in benefit-risk assessment."

Financial support for this research came from Innovative Medicines Initiative Joint Undertaking.

The news correspondents obtained a quote from the research from Pfizer, "Recommendations were drawn up based on the results of the case studies. A general pathway through the case studies was evident, with various classes of methodologies having roles to play at different stages. Descriptive and quantitative frameworks were widely used throughout to structure problems, with other methods such as metrics, estimation techniques and elicitation techniques providing ways to incorporate technical or numerical data from various sources. Similarly, tree diagrams and effects tables were universally adopted, with other visualisations available to suit specific methodologies or tasks as required. Every assessment was found to follow five broad stages: (i) Planning, (ii) Evidence gathering and data preparation, (iii) Analysis, (iv) Exploration and (v) Conclusion and dissemination. Adopting formal, structured approaches to benefit-risk assessment was feasible in real-world problems and facilitated clear, transparent decision-making. Prior to this work, no extensive practical application and appraisal of methodologies had been conducted using real-world case examples, leaving users with limited knowledge of their usefulness in the real world."

According to the news reporters, the research concluded: "The practical guidance provided here takes us one step closer to a harmonised approach to benefit-risk assessment from multiple perspectives."

Our news journalists report that additional information may be obtained by contacting D. Hughes, Worldwide Safety Strategy, Pfizer, New York, NY, United States. Additional authors for this research include E. Waddingham, S. Mt-Isa, A. Goginsky, E. Chan, G.F. Downey, C.E. Hallgreen, K.S. Hockley, J. Juhaeri, A. Lieftucht, M.A. Metcalf, R.A. Noel, L.D. Phillips, D. Ashby and A. Micaleff.

Researchers from Pontifical Catholic University Discuss Findings in HIV/AIDS (Structural domains within the HIV-1 mRNA and the ribosomal protein S25 influence cap-independent translation initiation)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Immune System Diseases and Conditions - HIV/AIDS. According to news reporting originating from Santiago, Chile, by NewsRx correspondents, research stated, "The 50 leader of the HIV-1 genomic RNA is a multifunctional region that folds into secondary/tertiary structures that regulate multiple processes during viral replication including translation initiation. In this work, we examine the internal ribosome entry site (IRES) located in the 50 leader that drives translation initiation of the viral Gag protein under conditions that hinder cap-dependent translation initiation."

Funders for this research include Fondo Nacional de Desarrollo Cientifico y Tecnologico, Fondo Nacional de Ciencia y Tecnologia del Gobierno de Chile, Iniciativa Cientifica Milenio del Ministerio de Economia, Fomento y Turismo, Proyecto Anillo, National Institutes of Health, UAB Cancer Center HIV-Associated Malignancy pilot research grant, RDCC, Comision Nacional de Investigacion Cientificay Tecnologica, MECESUP-USACH doctoral fellowships, Pontificia Universidad Catolica de Chile followed by a CONICYT fellowship.

Our news editors obtained a quote from the research from Pontifical Catholic University, "We show that activity of the HIV-1 IRES relies on ribosomal protein S25 (eS25). Additionally, a mechanistic and mutational analysis revealed that the HIV-1 IRES is modular in nature and that once the 40S ribosomal subunit is recruited to the IRES, translation initiates without the need of ribosome scanning."

According to the news editors, the research concluded: "These findings elucidate a mechanism of initiation by the HIV-1 IRES whereby a number of highly structured sites present within the HIV-1 50 leader leads to the recruitment of the 40S subunit directly at the site of initiation of protein synthesis."

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1111/febs.13756. This DOI is a link to an online electronic document that is either free or for purchase.

Cardiology

Researchers from Porto Alegre Hospital Clinic Discuss Findings in Cardiology (Comparing medication adherence tools scores and number of controlled diseases among low literacy patients discharged from a Brazilian cardiology ward)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Cardiology are presented in a new report. According to news reporting out of Porto Alegre, Brazil, by NewsRx editors, research stated, "Adherence to prescribed drug therapy is associated with lower rates of cardiovascular causes of death. In view of the relevance for public health, it is important to understand the relation between medication adherence tools' scores, especially in low literacy patients discharged from a cardiology ward."

Our news journalists obtained a quote from the research from Porto Alegre Hospital Clinic, "We aimed to assess: (a) the association between number of controlled clinical conditions and adherence tools scores, and (b) the correlation between the scores of three instruments to assess adherence. We conducted a prospective study and included patients discharged from a specialized cardiovascular ward in Brazil. The results of the Beliefs about Medicines questionnaire (BMQ), the Adherence to Refills and Medication Scale (ARMS) and the MedTake test were compared. Of 53 included patients, most of them were elderly, and did not complete primary school. On average, there were six health conditions per patient, where two of them were not controlled. ARMS was the only tool that was associated with number of controlled health conditions (r = -0.312, p< 0.05). Moreover, ARMS (average score 15.6 +/- 3.4) had significant correlation with MEDTAKE (r = 0.535, p< 0.01) and BMQ (r = 0.38, p< 0.01). BMQ and MEDTAKE were also positively correlated (r = 0.311, p< 0.05). Clinically, higher ARMS scores (> 12) suggest assumed non-adherence."

According to the news editors, the research concluded: "It is also negatively correlated with the number of controlled clinical conditions in low literacy elderlies with cardiovascular diseases."

Our news journalists report that additional information may be obtained by contacting P.C.B. Okumura, Porto Alegre Hospital Clinic, Div Clin Pharm, BR-90035903 Porto Alegre, RS, Brazil. Additional authors for this research include L.M. Okumura, W.C.T. Reis, R.R. Godoy, B.D. Cata-Preta, T.T. de Souza, M.L.D. Favero and C.J. Correr.

Nosocomial Infections

Researchers from Public Health Agency of Canada Report Details of New Studies and Findings in the Area of Nosocomial Infections (Results from the Canadian Nosocomial Infection Surveillance Program on Carbapenemase-Producing Enterobacteriaceae, ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Nosocomial Infections is the subject of a report. According to news reporting originating in Winnipeg, Canada, by NewsRx journalists, research stated, "Carbapenemase-producing Enterobacteriaceae (CPE) are increasing globally; here we report on the investigation of CPE in Canada over a 5-year period. Participating acute care facilities across Canada submitted carbapenem-nonsusceptible Enterobacteriaceae from 1 January 2010 to 31 December 2014 to the National Microbiology Laboratory."

The news reporters obtained a quote from the research from the Public Health Agency of Canada, "All CPE were characterized by antimicrobial susceptibilities, pulsed-field gel electrophoresis, multilocus sequence typing, and plasmid restriction fragment length polymorphism analysis and had patient data collected using a standard questionnaire. The 5-year incidence rate of CPE was 0.09 per 10,000 patient days and 0.07 per 1,000 admissions. There were a total of 261 CPE isolated from 238 patients in 58 hospitals during the study period. bla(KPC-3) (64.8%) and bla(NDM-1) (17.6%) represented the highest proportion of carbapenemase genes detected in Canadian isolates. Patients who had a history of medical attention during international travel accounted for 21% of CPE cases. The hospital 30-day all-cause mortality rate for the 5-year surveillance period was 17.1 per 100 CPE cases. No significant increase in the occurrence of CPE was observed from 2010 to 2014."

According to the news reporters, the research concluded: "Nosocomial transmission of CPE, as well as international health care, is driving its persistence within Canada."

For more information on this research see: Results from the Canadian Nosocomial Infection Surveillance Program on Carbapenemase-Producing Enterobacteriaceae, 2010 to 2014. Antimicrobial Agents and Chemotherapy, 2016;60(11):6787-6794. Antimicrobial Agents and Chemotherapy can be contacted at: Amer Soc Microbiology, 1752 N St NW, Washington, DC 20036-2904, USA. Researchers from Purdue University Report Details of New Studies and Findings in the Area of Cancer Biomarkers (Three-Dimensionally Functionalized Reverse Phase Glycoprotein Array for Cancer Biomarker Discovery and Validation)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Oncology - Cancer Biomarkers have been published. According to news originating from West Lafayette, Indiana, by NewsRx correspondents, research stated, "Glycoproteins have vast structural diversity that plays an important role in many biological processes and have great potential as disease biomarkers. Here, we report a novel functionalized reverse phase protein array (RPPA), termed polymer-based reverse phase glycoprotein array (polyGPA), to capture and profile glycoproteomes specifically, and validate glycoproteins."

Funders for this research include Division of Chemistry, National Cancer Institute, National Institute of General Medical Sciences.

Our news journalists obtained a quote from the research from Purdue University, "Nitrocellulose membrane functionalized with globular hydroxyaminodendrimers was used to covalently capture preoxidized glycans on glycoproteins from complex protein samples such as biofluids. The captured glycoproteins were subsequently detected using the same validated antibodies as in RPPA. We demonstrated the outstanding specificity, sensitivity, and quantitative capabilities of polyGPA by capturing and detecting purified as well as endogenous alpha-1-acid glycoprotein (AGP) in human plasma."

According to the news editors, the research concluded: "We further applied quantitative N-glycoproteomics and the strategy to validate a panel of glycoproteins identified as potential biomarkers for bladder cancer by analyzing urine glycoproteins from bladder cancer patients or matched healthy individuals."

The news correspondents report that additional information may be obtained from W.A. Tao, Purdue University, Center Canc Res, West Lafayette, IN 47907, United States. Additional authors for this research include H.A. Aguilar, L.N. Wang, A. Iliuk and W.A. Tao.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1021/jacs.6b10239. This DOI is a link to an online electronic document that is either free or for purchase.

Researchers from Putian University Provide Details of New Studies and Findings in the Area of Liver Cancer (Tissue Levels of Stefin A and Stefin B in Hepatocellular Carcinoma)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Oncology - Liver Cancer is the subject of a report. According to news reporting originating from Fujian, People's Republic of China, by NewsRx correspondents, research stated, "Stefins have been reported to be associated with the progression and metastasis of various malignant tumors. However, the expressions of stefins in hepatocellular carcinoma (HCC) have not been well-defined."

Funders for this research include National Natural Science Foundation of China, Scientific Special Foundation of the Education Department of Fujian Province, Science and Technology Projects in Putian City, Research Projects for Young and Middle-aged Teachers of Fujian Province.

Our news editors obtained a quote from the research from Putian University, "In this study, the protein levels of stefin A and stefin B were assessed by immunohistochemical staining, and the mRNA levels were quantified by real-time polymerase chain reaction in 85 primary HCC tissues, 85 surrounding non-cancerous tissues, and 9 normal hepatic tissues. The immunohistochemical staining of cathepsin B and cathepsin D, and the ratio of cathepsins to stefins were assessed. The mRNA expressions of stefin A and stefin B in HCC tissues were significantly higher than surrounding noncancerous tissues and normal hepatic tissues, respectively. A significant positive relationship of stefin A and stefin B was found with node metastasis, tumor size, and Edmondson grade for HCC. Univariate and multivariate analyses revealed that Edmondson grade and stefin B expression were independent factors associated with the risk of lymph node metastasis in HCC. The ratios of cathepsin B to stefin A, cathepsin D to stefin A, cathepsin B to stefin B and cathepsin D to stefin B of the HCC group were significantly higher than that of the surrounding noncancerous group. A significant positive correlation between the ratio of cathepsins to stefins (cathepsin B/stefin A, cathepsin B/stefin B and cathepsin D/stefin B) and node metastasis was demonstrated."

According to the news editors, the research concluded: "We concluded that high expressions of stefin A and stefin B may be an important factor contributing to the development and metastasis of HCC."

The news editors report that additional information may be obtained by contacting Y.Y. Lin, Dept. of Human Anatomy, Histology and Embryology, School of Basic Medical Science, Putian University, Putian, Fujian, People's Republic of China. Additional authors for this research include Z.W. Chen, Z.P. Lin, L.B. Lin, X.M. Yang, L.Y. Xu and Q. Xie.

Researchers from Qilu Hospital of Shandong University Report Recent Findings in Allergic Rhinitis (Role of interleukin-6 polymorphisms in the development of allergic rhinitis)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Immune System Diseases and Conditions - Allergic Rhinitis are presented in a new report. According to news reporting from Jinan, People's Republic of China, by NewsRx journalists, research stated, "The aim of this study was to investigate the role played by the IL-6 rs1800795 (-174G/C) and rs1800796 (-572G>C) polymorphisms in the susceptibility to allergic rhinitis in a Chinese population. A total of 265 patients with allergic rhinitis and 265 controls from our hospital were enrolled in this study."

The news correspondents obtained a quote from the research from the Qilu Hospital of Shandong University, "The IL-6 rs1800795 and rs1800796 polymorphisms were genotyped by polymerase chain reaction coupled with restriction fragment length polymorphism. The results of the ch(2) statistical analysis revealed significant differences in the allele frequencies of IL-6 rs1800795 between patients with allergic rhinitis and controls (ch(2)=4.52, p=0.03). Multivariate logistic regression analyses revealed that individuals with the C allele of IL-6 rs1800795 were susceptible to increased risk of allergic rhinitis, compared to those expressing the G allele (adjusted OR=1.31; 95%CI=1.01-1.68)."

According to the news reporters, the research concluded: "The results of our study indicated that the IL-6 rs1800795 polymorphism was associated with an increased risk of allergic rhinitis."

For more information on this research see: Role of interleukin-6 polymorphisms in the development of allergic rhinitis. Genetics and Molecular Research [electronic Resource], 2016;15(1):.

Our news journalists report that additional information may be obtained by contacting N. Zhao, ENT Dept. of Qilu Hospital of Shandong University, Jinan, People's Republic of China. Additional authors for this research include H.J. Liu, Y.Y. Sun and Y.Z Li.

Researchers from Queensland University of Technology Describe Findings in Depression (Shared Genetic Factors in the Co-Occurrence of Depression and Fatigue)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Mental Health Diseases and Conditions - Depression. According to news reporting originating in Brisbane, Australia, by NewsRx journalists, research stated, "Depression and fatigue have previously been suggested to share an underlying genetic contribution. The present study aims to investigate and characterize the familiality and genetic relationship between depression and fatigue."

The news reporters obtained a quote from the research from the Queensland University of Technology, "The familiality of depression and fatigue was assessed by calculating relative risks, measured by the prevalence ratio, within 643 monozygotic MZ) and 577 dizygotic DZ) twin pairs. Bi-variate twin modeling was utilized to assess the magnitude of shared heritability between depression and fatigue. Finally, the relationship between depression and fatigue was investigated using the co-twin control method, to determine whether the association is explained by causal or non-causal models. We observed an increased risk of fatigue in co-twins of probands with depression and increased risk of depression in co-twins of probands with fatigue. Higher risks were observed in MZ compared to DZ twin pairs, and bivariate heritability analyses indicated significant genetic components for depression and fatigue, with heritability estimates of 48% and 41%, respectively. Importantly, a significant additive genetic correlation of 0.71 [95% CI = 0.51-0.92) and bivariate heritability of 21% [95% CI = 10-35%] was observed between depression and fatigue. Furthermore, results from the co-twin control method indicate a non-causal genetic relationship that likely explains the association between depression and fatigue."

According to the news reporters, the research concluded: "Notably, the contribution of shared genetic factors remained significant, independent of the overlapping symptoms, indicating that the relationship between co-occurring depression and fatigue is primarily due to shared genetic factors rather than overlapping symptomatology."

Our news correspondents report that additional information may be obtained by contacting E.C. Corfield, Queensland University of Technology, Inst Hlth & Biomed Innovat, Fac Hlth, Brisbane, Qld, Australia. Additional authors for this research include N.G. Martin and D.R. Nyholt.

Researchers from Queensland University of Technology Report Recent Findings in Type 1 Diabetes Mellitus (Vision Recovery Despite Retinal Ganglion Cell Loss in Leber's Hereditary Optic Neuropathy)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Nutritional and Metabolic Diseases and Conditions - Type 1 Diabetes Mellitus have been published. According to news reporting out of Brisbane, Australia, by NewsRx editors, the research stated, "To report vision recovery in a single case of Leber's hereditary optic neuropathy (LHON) (mtDNA14484/ND6 mutation) with longitudinal documentation of retinal ganglion cell layer by ocular coherence tomography (OCT) that includes the pre-onset, acute, and chronic stages of vision loss. We report LHON in a 16-year-old male patient with Type 1 diabetes and known and documented family history of LHON."

Our news journalists obtained a quote from the research from the Queensland University of Technology, "The patient presented with best-corrected visual acuities of right eye 20-150 and left eye 20-25-. His retinal nerve fiber layer had thickened compared with baseline measures obtained 19 months before the onset of vision loss. Vision rapidly reduced to 'hand movements' vision in each eye over the following 2 months. Despite OCT-documented significant recalcitrant loss of ganglion cell layer, visual acuity remarkably recovered to right eye 20/40+ left eye 20/50+ 16 months after onset of neuropathy. A selective loss of ganglion cells and nerve fiber layer can be documented in LHON."

According to the news editors, the research concluded: "Significant recovery of visual acuity can occur without apparent structural recovery."

Our news journalists report that additional information may be obtained by contacting A.L. Webber, Queensland University of Technology, Sch Optometry & Vis Sci, Brisbane, Qld 4001, Australia.

Keywords for this news article include: Brisbane, Australia, Australia and New Zealand, Type 1 Diabetes Mellitus, Nutritional and Metabolic Diseases and Conditions, Optic Nerve Diseases and Conditions, Insulin Dependent Diabetes Mellitus, Retinal Ganglion Cells, Risk and Prevention, Retinal Neurons, Type 1 Diabetes, Neuropathy, Genetics, Queensland University of Technology.

Researchers from RWTH Aachen University Detail Findings in Microbiology and Biotechnology (Ustilago maydis produces itaconic acid via the unusual intermediate trans-aconitate)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Biotechnology - Microbiology and Biotechnology are presented in a new report. According to news reporting from Aachen, Germany, by NewsRx journalists, research stated, "Itaconic acid is an important biomass-derived chemical building block but has also recently been identified as a metabolite produced in mammals, which has antimicrobial activity. The biosynthetic pathway of itaconic acid has been elucidated in the ascomycetous fungus Aspergillus terreus and in human macrophages."

Financial supporters for this research include SFB 987 ‘Microbial Diversity in Environmental Signal Response’, Excellence Initiative of the German federal and state governments as a part of the Cluster of Excellence ‘Tailor-Made Fuels from Biomass’ (TMFB, E.G.).

The news correspondents obtained a quote from the research from RWTH Aachen University, "In both organisms itaconic acid is generated by decarboxylation of the tricarboxylic acid (TCA) cycle intermediate cis-aconitate. Here, we show that the basidiomycetous fungus Ustilago maydis uses an alternative pathway and produces itaconic acid via trans-aconitate, the thermodynamically favoured isomer of cis-aconitate. We have identified a gene cluster that contains all genes involved in itaconic acid formation. Trans-aconitate is generated from cis-aconitate by a cytosolic aconitate-D-isomerase (Adi1) that belongs to the PrpF family of proteins involved in bacterial propionate degradation. Decarboxylation of trans-aconitate is catalyzed by a novel enzyme, trans-aconitate decarboxylase (Tad1). Tad1 displays significant sequence similarity with bacterial 3-carboxy-cis,cis-muconate lactonizing enzymes (CMLE). This suggests that U. maydis has evolved an alternative biosynthetic pathway for itaconate production using the toxic intermediate trans-aconitate. Overexpression of a pathway-specific transcription factor (Ria1) or a mitochondrial tricarboxylic acid transporter (Mtt1) resulted in a twofold increase in itaconate yield."

According to the news reporters, the research concluded: "Therefore, our findings offer new strategies for biotechnological production of this valuable biomass-derived chemical."

Our news journalists report that additional information may be obtained by contacting E. Geiser, iAMB - Institute of Applied Microbiology, ABBt - Aachen Biology and Biotechnology, RWTH Aachen University, Worringergeweg 1, D-52074, Aachen, Germany. Additional authors for this research include S.K. Przybilla, A. Friedrich, W. Buckel, N. Wierckx, L.M. Blank and M. Bolker.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1111/1751-7915.12329. This DOI is a link to an online electronic document that is either free or for purchase.

Researchers from RWTH Aachen University Report on Findings in Parkinson's Disease (Mice lacking Faim2 show increased cell death in the MPTP mouse model of Parkinson disease)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Parkinson's disease have been presented. According to news reporting from Aachen, Germany, by NewsRx journalists, research stated, "The death receptor Fas/CD95 mediates apoptotic cell death in response to external stimuli. In neurons, Fas-induced apoptosis is prevented by Fas-apoptotic inhibitory molecule 2 (Faim2)."

Financial support for this research came from Interdisciplinary Center for Clinical Research (IZKF) Aachen.

The news correspondents obtained a quote from the research from RWTH Aachen University, "Mice lacking Faim2 showed increased neurodegeneration in animal models of stroke and bacterial meningitis. We therefore tested the relevance of Faim2 in a classical animal model of Parkinson disease and determined the toxicity of 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) in Faim2-deficient mice. Without MPTP treatment, there was no difference in the dopaminergic system between Faim2-deficient mice and control mice. MPTP was applied i.p. in doses of 30mg per kg on five consecutive days. Fourteen days after the last MPTP injection, the number of dopaminergic neurons in the lateral substantia nigra, assayed by stereological counting, was reduced by 39% in control mice and 53% in Faim2-deficient mice. The density of dopaminergic fibers in the dorsal striatum was reduced by 36% in control mice and 69% in Faim2-deficient mice, in the ventral striatum 44% in control mice and 76% in Faim2-deficient mice. Fiber density recovered at 90 days after MPTP with similar density in both groups. Striatal catecholamine levels were reduced by 81-84% in both groups and recovered at 90 days. Faim2 expression was documented in mouse midbrain using quantitative reverse transcription-PCR (qRT-PCR) and found decreased after MPTP administration. Taken together, our findings demonstrate increased degeneration of dopaminergic neurons with Faim2 deficiency, indicating that Fas-induced apoptosis contributes to cell death in the MPTP mouse model."

According to the news reporters, the research concluded: "Along with the decreased expression of Faim2 after MPTP, this finding indicates that boosting Faim2 function might represent a therapeutic strategy for Parkinson disease."

Our news journalists report that additional information may be obtained by contacting B.H. Falkenburger, Rhein Westfälisch Aachen, Aachen, Germany.
Researchers from Rabin Medical Center Report Recent Findings in Obstetrics and Gynecology (Pregnancy Outcome in Women with Decreased Sensation of Fetal Movements at Term According to Parity)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Women's Health - Obstetrics and Gynecology is the subject of a report. According to news reporting originating in Petah Tikva, Israel, by NewsRx journalists, research stated, "Decreased sensation of fetal movements (DFM) is a common maternal complaint. Thus, we aimed to evaluate the association between DFM and pregnancy outcome in singleton gestation at term according to parity."

The news reporters obtained a quote from the research from Rabin Medical Center, "A retrospective cohort study of singleton pregnancies at term between 2008 and 2013. Eligibility was limited to women carrying a fetus with no known structural or chromosomnal anomalies, at 37+0/7 to 42+0/7 weeks of gestation. Women presenting to the delivery ward with DFM were compared with women without similar complaints. Overall, 12,564 nulliparous women and 25,292 multiparous women gave birth during the study period; of them, 300 nulliparous women (2.4%) and 525 multiparous women (2.1%) complained of DFM. For nulliparous women, after adjusting for potential confounders, DFM was associated with antepartum fetal death (aOR 4.6 [95% CI 1.1-19.8]), cesarean delivery (CD) (aOR 1.3 [95% CI 1.01-1.8]), 1-minute Apgar score less than 7 (aOR 2.3 [95% CI 1.5-3.5]) and neonatal seizures (aOR 3.2 [95% CI 1.3-8.2]). For multiparous women, DFM was associated with unscheduled CD (aOR 2.7 [95% CI 1.6-4.6]) and CD indicated by intermediate/abnormal fetal heart rate tracing (aOR 4.8 [95% CI 2.8-8.4]). DFM carries different outcomes according to parity."

According to the news reporters, the research concluded: "Although for nulliparous women, DFM is associated with increased risk of CD and immediate adverse perinatal outcome, for multiparous women it is associated with increased risk for CD, with no immediate increased risk for adverse perinatal outcome."

Our news correspondents report that additional information may be obtained by contacting A. Aviram, Helen Schneider Hospital for Women, Rabin Medical Center, Petah Tikva, Israel. Additional authors for this research include A. Shmueli, L. Hiersch, E. Ashwal, A.
Researchers from Ramon y Cajal Hospital Report on Findings in Aortitis (Aortitis With Associated Left Main Coronary Artery Stenosis: Role of Cardiac Computed Tomography)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Heart Disorders and Diseases - Aortitis have been published. According to news originating from Madrid, Spain, by NewsRx correspondents, research stated, "We report on a 49-year-old man who presented to the emergency department with progressive angina. Echocardiography displayed severe aortic regurgitation and aortic valve thickening."

Our news journalists obtained a quote from the research from Ramon y Cajal Hospital, "The suspected diagnosis was acute aortic syndrome. Cardiac computed tomography showed circumferential thickening of the aortic wall and left main coronary artery ostial stenosis. Histologic examination showed diffuse aortic inflammation. No damage of any other organ or vascular structure was reported, and the final diagnosis was nonspecific aortitis."

According to the news editors, the research concluded: "Differential diagnosis, prognosis, and therapeutic strategies are discussed."

The news correspondents report that additional information may be obtained from G.L.A. Salinas, Hosp Ramon & Cajal, Dept. of Cardiol, E-28034 Madrid, Spain. Additional authors for this research include S.F. Santos, I.P. Pagnon, J.M. Hycka, I. Pecharroman, M.S. Fernandez, M.P. Izco, J.J. Jimenez-Nacher, C. Fernandez-Golfin and J.L. Zamorano.

Researchers from Regina Elena Cancer Institute Report Findings in Apoptosis (Apoptosis induced by a HIPK2 full-length-specific siRNA is due to off-target effects rather than prevalence of HIPK2-De8 isoform)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Apoptosis have been published. According to news originating from Rome, Italy, by NewsRx correspondents, research stated, "Small interfering RNAs (siRNAs) are widely used to study gene function and extensively exploited for their potential therapeutic applications. HIPK2 is an evolutionary conserved kinase that binds and phosphorylates several proteins directly or indirectly related to apoptosis."

Our news journalists obtained a quote from the research from Regina Elena Cancer Institute, "Recently, an alternatively spliced isoform skipping 81 nucleotides of exon 8 (Hipk2-De8) has been described. Selective depletion of Hipk2 full-length (Hipk2-FL) with a specific siRNA that spares the Hipk2-De8 isoform has been shown to strongly induce apoptosis, suggesting an unpredicted dominant-negative effect of Hipk2-FL over the De8 isoform. From this observation, we sought to take advantage and assessed the therapeutic potential of generating Hipk2 isoform unbalance in tumor-initiating cells derived from colorectal cancer patients. Strong reduction of cell viability was induced in vitro and in vivo by the originally described exon 8-specific siRNA, supporting a potential therapeutic application. However, validation analyses performed with additional exon8-specific siRNAs with different stabilities showed that all exon8-targeting siRNAs can induce comparable Hipk2 isoform unbalance but only the originally reported e8-siRNA promotes cell death."

According to the news editors, the research concluded: "These data show that loss of viability does not depend on the prevalence of Hipk2-De8 isoform but it is rather due to microRNA-like off-target effects."

For more information on this research see: Apoptosis induced by a HIPK2 full-length-specific siRNA is due to off-target effects rather than prevalence of HIPK2-De8 isoform. Oncotarget, 2016;7(2):1675-86.

The news correspondents report that additional information may be obtained from G. Di Rocco, Dept. of Research, Advanced Diagnostics and Technological Innovation, Regina Elena National Cancer Institute, Rome, Italy. Additional authors for this research include A. Verdina, V. Gatti, I. Virdia, G. Toietta, M. Todaro, G. Stassi and S. Soddu.

Researchers from Regina Elena National Institute for Cancer Treatment and Research Report Details of New Studies and Findings in the Area of Acute Lymphoblastic Leukemia (Ponatinib Induces a Persistent Molecular Response and Graft-versus-Host ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Oncology - Acute Lymphoblastic Leukemia have been published. According to news reporting out of Rome, Italy, by NewsRx editors, research stated, "We describe the case of a patient with a Philadelphia-positive (Ph+) acute lymphoblastic leukemia (ALL) treated with dasatinib plus steroids as the first-line therapy who achieved a molecular complete remission and then underwent a matched, unrelated donor allogeneic transplant. Five months after the transplant, he experienced a disease relapse with an T315I mutation, which was resistant to salvage chemotherapy."

Our news journalists obtained a quote from the research from Regina Elena National Institute for Cancer Treatment and Research, "Once the details of the T315I mutation were acquired, we initiated ponatinib treatment at a standard dosage and observed a rapid decrease of minimal residual disease (MRD) at molecular assessment. The bone marrow evaluation after 2, 3, 6, 10 and 13 months was negative for MRD. After starting ponatinib, the patient experienced a skin graft-versus-host disease (GVHD), whereas no occurrence of GVHD was observed after transplant, suggesting that the efficacy of ponatinib could be related not only to the direct antileukemic effect, but also to its ability to promote an indirect graft-versus-leukemia effect."

According to the news editors, the research concluded: "Ponatinib was well tolerated but a thyroid dysfunction mimicking a cardiovascular toxicity was observed and solved with hormonal substitutive treatment."

Our news journalists report that additional information may be obtained by contacting R. Daniela, Regina Elena Inst Canc Res, Hematol & Stem Cell Transplant Unit, IT-00144 Rome, Italy. Additional authors for this research include F. Marchesi, G. De Angelis, L. Elia, E. Salvatorelli, S. Gumenyuk, F. Palombi, F. Pisani, A. Romano, A. Spadea, E. Papa, M. Canfora, W. Arcese and A. Mengarelli.

Researchers from Research Foundation Report Details of New Studies and Findings in the Area of Public Health (Shaping Public Health Initiatives in Kidney Diseases: The Peer Kidney Care Initiative)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Public Health. According to news reporting from Minneapolis, Minnesota, by NewsRx journalists, research stated, "While broad-based societal efforts to improve public health have targeted disorders such as cardiovascular disease and cancer for several decades, efforts devoted to kidney disease have developed only more recently. The Peer Kidney Care Initiative, a novel effort designed to address knowledge gaps in the care of patients with kidney disease, examines key disease processes, the roles of geography and seasonality on outcomes, and longitudinal trends in outcomes over time."

The news correspondents obtained a quote from the research from Research Foundation, "Admissions for gastrointestinal bleeds increased approximately 28% between 2004 and 2011 in prevalent patients. Infection with Clostridium difficile increased nearly 70% between 2003 and 2010 in patients within a year of initiation. Admissions for heart failure in prevalent patients decreased approximately 25% between 2004 and 2012, but admissions for volume overload increased a nearly equal amount. Incidence rates varied substantially by geographic region, such that unadjusted rates in the highest region were nearly double than those in the lowest. There was seasonal variation in all-cause mortality of approximately 15-20% in both incident and prevalent patients, suggesting a link between cardiovascular events and seasonally related environmental conditions. New cases of end-stage renal disease fell from 385 per million population in 2003 to 344 in 2012, a decline of approximately 10%."

According to the news reporters, the research concluded: "Peer complements existing kidney disease epidemiologic efforts by examining specific actionable disease entities, exploring geographic variation in care, highlighting the role of seasonality on outcomes, and emphasizing the importance of trending outcomes over time as overall societal progress is being made."

Our news journalists report that additional information may be obtained by contacting J.B. Wetmore, Chronic Disease Research Group, Minneapolis Medical Research Foundation, Minneapolis, MN, United States. Additional authors for this research include D.T. Gilbertson and A.J Collins.

Researchers from Research Institute for Clinical Oncology Detail New Studies and Findings in the Area of Cancer Prevention (Biophysical Approach to Mechanisms of Cancer Prevention and Treatment with Green Tea Catechins)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Oncology - Cancer Prevention have been published. According to news reporting from Saitama, Japan, by NewsRx journalists, research stated, "Green tea catechin and green tea extract are now recognized as non-toxic cancer preventives for humans. We first review our brief historical development of green tea cancer prevention."

The news correspondents obtained a quote from the research from Research Institute for Clinical Oncology, "Based on exciting evidence that green tea catechin, (-)-epigallocatechin gallate (EGCG) in drinking water inhibited lung metastasis of B16 melanoma cells, we and other researchers have studied the inhibitory mechanisms of metastasis with green tea catechins using biomechanical tools, atomic force microscopy (AFM) and microfluidic optical stretcher. Specifically, determination of biophysical properties of cancer cells, low cell stiffness, and high deformability in relation to migration, along with biophysical effects, were studied by treatment with green tea catechins. The study with AFM revealed that low average values of Young's moduli, indicating low cell stiffness, are closely associated with strong potential of cell migration and metastasis for various cancer cells. It is important to note that treatments with EGCG and green tea extract elevated the average values of Young's moduli resulting in increased stiffness (large elasticity) of melanomas and various cancer cells."

According to the news reporters, the research concluded: "We discuss here the biophysical basis of multifunctions of green tea catechins and green tea extract leading to beneficial effects for cancer prevention and treatment."

For more information on this research see: Biophysical Approach to Mechanisms of Cancer Prevention and Treatment with Green Tea Catechins. *Molecules*, 2016;21(11):2157-2173. *Molecules* can be contacted at: Mdpi Ag, St Alban-Anlage 66, Ch-4052 Basel, Switzerland. Researchers from Royal Brisbane and Women's Hospital Describe Findings in Cystic Fibrosis (Bayesian Estimation of Tobramycin Exposure in Patients with Cystic Fibrosis)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Lung Diseases and Conditions - Cystic Fibrosis. According to news reporting out of Brisbane, Australia, by NewsRx editors, research stated, "Fixed tobramycin (mg/kg) dosing is often inappropriate in patients with cystic fibrosis (CF), as pharmacokinetics are highly variable. The area under the concentration-time curve (AUC) is an exposure metric suited to monitoring in this population."

Our news journalists obtained a quote from the research from Royal Brisbane and Women's Hospital, "Bayesian strategies to estimate AUC have been available for over 20 years but are not standard practice in the clinical setting. To assess their suitability for use in clinical practice, three AUC estimation methods using limited sampling were compared to measured true exposure by using intensive sampling tobramycin data. Adults prescribed once daily intravenous tobramycin had eight concentrations taken over 24 h. An estimate of true exposure within one dosing interval was calculated using the trapezoidal method and compared to three alternate estimates determined using (i) a two-sample log-linear regression (LLR) method (local hospital practice); (ii) a Bayesian estimate using one concentration (AUC(1)); and (iii) a Bayesian estimate using two concentrations (AUC(2)). Each method was evaluated against the true measured exposure by a Bland-Altman analysis. Twelve patients with a median (range) age and weight of 25 (18 to 36) years and 66.5 (51 to 76) kg, respectively, were recruited. There was good agreement between the true exposure and the three alternate estimates of AUC, with a mean AUC bias of < 10 mg/liter center dot h in each case, i.e., -8.2 (LLR), 3.8 (AUC(1)), and 1.0 (AUC(2)). Bayesian analysis-based and LLR estimation methods of tobramycin AUC are equivalent to true exposure estimation. All three methods may be suitable for use in the clinical setting; however, a one-sample Bayesian method may be most useful in ambulatory patients for which coordinating blood samples is difficult."

According to the news editors, the research concluded: "Suitably powered, randomized clinical trials are required to assess patient outcomes."

For more information on this research see: Bayesian Estimation of Tobramycin Exposure in Patients with Cystic Fibrosis. Antimicrobial Agents and Chemotherapy, 2016;60 (11):6698-6702. Antimicrobial Agents and Chemotherapy can be contacted at: Amer Soc Microbiology, 1752 N St NW, Washington, DC 20036-2904, USA. Researchers from Royal College of Surgeons in Ireland Discuss Findings in Cardiovascular Research (Impact analysis studies of clinical prediction rules relevant to primary care: a systematic review)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Cardiovascular Research is now available. According to news reporting originating in Dublin, Ireland, by NewsRx journalists, research stated, "Following appropriate validation, clinical prediction rules (CPRs) should undergo impact analysis to evaluate their effect on patient care. The aim of this systematic review is to narratively review and critically appraise CPR impact analysis studies relevant to primary care. Primary care. Adults and children."

The news reporters obtained a quote from the research from the Royal College of Surgeons in Ireland, "Studies that implemented the CPR compared to usual care were included. Randomised controlled trial (RCT), controlled before-after, and interrupted time series. Physician behaviour and/or patient outcomes. A total of 18 studies, incorporating 14 unique CPRs, were included. The main study design was RCT (n=13). Overall, 10 studies reported an improvement in primary outcome with CPR implementation. Of 6 musculoskeletal studies, 5 were effective in altering targeted physician behaviour in ordering imaging for patients presenting with ankle, knee and neck musculoskeletal injuries. Of 6 cardiovascular studies, 4 implemented cardiovascular risk scores, and 3 reported no impact on physician behaviour outcomes, such as prescribing and referral, or patient outcomes, such as reduction in serum lipid levels. 2 studies examined CPRs in decision-making for patients presenting with chest pain and reduced inappropriate admissions. Of 5 respiratory studies, 2 were effective in reducing antibiotic prescribing for sore throat following CPR implementation. Overall, study methodological quality was often unclear due to incomplete reporting. Despite increasing interest in developing and validating CPRs relevant to primary care, relatively few have gone through impact analysis."

According to the news reporters, the research concluded: "To date, research has focused on a small number of CPRs across few clinical domains only."

For more information on this research see: Impact analysis studies of clinical prediction rules relevant to primary care: a systematic review. *Bmj Open*, 2016;6(3):e009957. (BMJ Publishing Group - group.bmj.com; Bmj Open - bmjopen.bmj.com)

Researchers from Royal Melbourne Hospital Report Recent Findings in Pulmonary Hypertension (Normalisation of hypoxaemia following successful percutaneous closure of a bidirectional shunting secundum atrial septal defect without pulmonary ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Lung Diseases and Conditions - Pulmonary Hypertension have been presented. According to news reporting originating from Melbourne, Australia, by NewsRx correspondents, research stated, "Atrial septal defects (ASD) are an uncommon cause of dyspnoea."

Our news editors obtained a quote from the research from Royal Melbourne Hospital, "A high index of suspicion is required, and further investigation should be prompted in patients with unexplained hypoxaemia, particularly those with pulmonary hypertension. Hypoxic ASD without pulmonary hypertension are rare, and only a handful of cases have been published."

According to the news editors, the research concluded: "We present a middle-aged man with progressive dyspnoea with a successfully closed ASD without pulmonary hypertension caused by elevated right ventricular pressures secondary to an idiopathic cardiomyopathy."

The news editors report that additional information may be obtained by contacting R.D. Anderson, Royal Melbourne Hospital, Dept. of Cardiol, Melbourne, Vic 3050, Australia. Additional authors for this research include W. Wilson, J. Morton and A. Aggarwal.

Researchers from Royal North Shore Hospital Provide Details of New Studies and Findings in the Area of Diabetes [Management of patients with diabetes and CKD: conclusions from a "Kidney Disease: Improving Global Outcomes" (KDIGO) Controversies ...]

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Diabetes have been presented. According to news reporting originating from Sydney, Australia, by NewsRx correspondents, research stated, "The prevalence of diabetes around the world has reached epidemic proportions and is projected to increase to 642 million people by 2040. Diabetes is already the leading cause of end-stage kidney disease (ESKD) in most developed countries, and the growth in the number of people with ESKD around the world parallels the increase in diabetes."

Our news editors obtained a quote from the research from Royal North Shore Hospital, "The presence of kidney disease is associated with a markedly elevated risk of cardiovascular disease and death in people with diabetes. Several new therapies and novel investigational agents targeting chronic kidney disease patients with diabetes are now under development."

According to the news editors, the research concluded: "This conference was convened to assess our current state of knowledge regarding optimal glycemic control, current antidiabetic agents and their safety, and new therapies being developed to improve kidney function and cardiovascular outcomes for this vulnerable population."

The news editors report that additional information may be obtained by contacting V. Perkovic, Royal North Shore Hosp, Sydney, NSW, Australia. Additional authors for this research include R. Agarwal, P. Fioretto, B.R. Hemmelgarn, A. Levin, M.C. Thomas, C. Wanner, B.L. Kasiske, D.C. Wheeler and P.H. Groop.

Heart Disorders and Diseases - Heart Disease

Researchers from Royal Perth Hospital Provide Details of New Studies and Findings in the Area of Heart Disease (Angiographic progression of coronary atherosclerosis in patients with familial hypercholesterolaemia treated with non-statin ...)
2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Heart Disorders and Diseases - Heart Disease. According to news reporting originating in Perth, Australia, by NewsRx journalists, research stated, "Familial hypercholesterolaemia (FH) profoundly increases the risk of coronary artery disease (CAD). We investigated whether diet and a bile-acid sequestrant decrease coronary atherosclerosis in patients with FH."

The news reporters obtained a quote from the research from Royal Perth Hospital, "We identified 26 men with FH and CAD, participating in the St Thomas' Atherosclerosis Regression Study, who had been randomized to receive a fat-modified diet plus cholestyramine (8 g twice daily) (DC, n = 12) or usual care (UC, n = 14), and investigated the relative effects of these treatments on the angiographic progression of coronary atherosclerosis over 39 months. FH was defined as probable/definite according to Dutch Lipid Clinic Network criteria; mean FH score was 8.7 (range 6 - 15) and mean baseline low-density lipoprotein cholesterol (LDL-Ch) concentration was 5.4 (SD 1.4) mmol/L. Coronary atherosclerosis was assessed by serial quantitative angiography as the global changes in mean and minimum absolute width of segments (MAWS and MinAWS, respectively). Mean plasma LDL-Ch concentration fell by 35% with DC and remained significantly (p < 0.001) lower during the trial at 3.78 (SD 0.98) mmol/L compared with UC at 4.89 (1.04). MAWS decreased by 0.252 (SEM 0.072) mm in the UC group and by 0.001 (0.065) mm in the DC group (p = 0.007), with corresponding reductions in MinAWS of 0.290 (0.087) mm and 0.013 (0.058) mm (p = 0.009); these changes were significant after adjusting for baseline variables, including coronary luminal dimensions and lipoprotein(a). Progression was observed in 7 patients (50%) on UC and 3 (25%) on DC (p = 0.19), with regression in no patients (0%) and 3 patients (25%) (p < 0.05), respectively."

According to the news reporters, the research concluded: "This investigation, carried out in the pre-statin era, demonstrates that a prudent diet and cholestyramine could improve the course of coronary atherosclerosis in men with phenotypic FH through sustained reductions in LDL-Ch."

Our news correspondents report that additional information may be obtained by contacting G.F. Watts, Royal Perth Hospital, Dept. of Cardiol, Cardiometab Serv, Lipid Disorders Clin, Perth, WA, Australia. Additional authors for this research include J. Pang, D.C. Chan, J.N.H. Brunt and B. Lewis.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1016/j.atherosclerosis.2016.07.923. This DOI is a link to an online electronic document that is either free or for purchase.

Researchers from Saga University Describe Findings in Thoracoscopy (Survival outcomes of 220 consecutive patients with three-staged thoracoscopic esophagectomy)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Surgical Procedures - Thoracoscopy are discussed in a new report. According to news reporting originating in Saga, Japan, by NewsRx journalists, research stated, "Patients with thoracic esophageal cancer are often treated by minimally invasive esophagectomy. However, the long-term survival benefits of minimally invasive esophagectomy remain unclear."

The news reporters obtained a quote from the research from Saga University, "Two approaches are available for thoracoscopic surgery: one with the patient in the left lateral decubitus position (LLDP), and the other with the patient in the prone position (PP). We investigated the survival benefit of thoracoscopic esophagectomy according to the tumor stage and patient position during the thoracoscopic procedure. We reviewed the records of 220 consecutive patients with esophageal cancer treated from 1998 to 2012. In total, 146 and 74 patients were treated with thoracoscopic esophagectomy in the LLDP and PP, respectively. No patients were initially proposed to be candidates for esophagectomy by thoracotomy during the study period. Data collection was performed with a focus on survival and recurrent disease. Among all the 220 patients, the overall 5-year survival rates were 83.7%, 74.1%, 45.5%, 78.6%, 44.2%, 29.4% and 24.3% in the patients with pStage IA, IB, IIA, IIB, IIIA, IIIB and IIIC disease, respectively. Despite the greater number of dissected mediastinal lymph nodes in the PP procedure, there were no significant differences in the survival curves between the LLDP and PP procedures. The long-term results of thoracoscopic esophagectomy are comparable and acceptable."

According to the news reporters, the research concluded: "The PP procedure was not confirmed to offer a superior survival benefit to the LLDP procedure in this retrospective study."

Our news correspondents report that additional information may be obtained by contacting H. Noshiro, Saga Univ, Dept. of Surg, Fac Med, Saga 8498501, Japan. Additional authors for this research include Y. Yoda, M. Hiraki, H. Kono, S. Miyake, A. Uchiyama and E. Nagai.

Keywords for this news article include: Saga, Japan, Asia, Digestive System Surgical Procedures, Thoracic Surgical Procedures, Gastroenterology, Esophagectomy, Thoracoscopy, Surgery, Saga University.

Oncology - Acute Myeloid Leukemia

Researchers from Saga University Report Findings in Acute Myeloid Leukemia (Preclinical activity of the novel B-cell-specific Moloney murine leukemia virus integration site 1 inhibitor PTC-209 in acute myeloid leukemia: Implications for ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Oncology - Acute Myeloid Leukemia have been presented. According to news reporting originating from Saga, Japan, by NewsRx correspondents, research stated, "Curing patients with acute myeloid leukemia (AML) remains a therapeutic challenge. The polycomb complex protein B-cell-specific Moloney murine leukemia virus integration site 1 (BMI-1) is required for the self-renewal and maintenance of leukemia stem cells."

Financial supporters for this research include Ministry of Education, Culture, Sports, Science, and Technology, Princess Takamatsu Cancer Research Fund, Osaka Cancer Research Foundation, National Institutes of Health, Cancer Center Support Grant, Paul and Mary Haas Chair in Genetics.

Our news editors obtained a quote from the research from Saga University, "We investigated the prognostic significance of BMI-1 in AML and the effects of a novel small molecule selective inhibitor of BMI-1, PTC-209. BMI-1 protein expression was determined in 511 newly diagnosed AML patients together with 207 other proteins using reverse-phase protein array technology. Patients with unfavorable cytogenetics according to Southwest Oncology Group criteria had higher levels of BMI-1 compared to those with favorable (p=0.0006) or intermediate cytogenetics (p=0.0061), and patients with higher levels of BMI-1 had worse overall survival (55.3 weeks vs. 42.8 weeks, p=0.046). Treatment with PTC-209 reduced protein level of BMI-1 and its downstream target mono-ubiquitinated histone H2A and triggered several molecular events consistent with the induction of apoptosis, this is, loss of mitochondrial membrane potential, caspase-3 cleavage, BAX activation, and phosphatidylserine externalization. PTC-209 induced apoptosis in patient-derived CD34(+)CD38(low/-) AML cells and, less prominently, in CD34(-) differentiated AML cells. BMI-1 reduction by PTC-209 directly correlated with apoptosis induction in CD34(+) primary AML cells (r=0.71, p=0.022). However, basal BMI-1 expression was not a determinant of AML sensitivity."

According to the news editors, the research concluded: "BMI-1 inhibition, which targets a primitive AML cell population, might offer a novel therapeutic strategy for AML."

The news editors report that additional information may be obtained by contacting Y. Nishida, Division of Medicine, Dept. of Hematology, Respiratory Medicine and Oncology, Saga University, Saga, Japan. Additional authors for this research include A. Maeda, D. Chachad, J. Ishizawa, Y.H. Qiu, S.M. Kornblau, S. Kimura, M. Andreeff and K. Kojima.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1111/cas.12833. This DOI is a link to an online electronic document that is either free or for purchase.
Researchers from Salus University Detail Findings in Blindness [The R838S Mutation in Retinal Guanylyl Cyclase 1 (RetGC1) Alters Calcium Sensitivity of cGMP Synthesis in the Retina and Causes Blindness in Transgenic Mice]

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Eye Diseases and Conditions - Blindness is the subject of a report. According to news originating from Elkins Park, Pennsylvania, by NewsRx correspondents, research stated, "Substitutions of Arg(838) in the dimerization domain of a human retinal membrane guanylyl cyclase 1 (RetGC1) linked to autosomal dominant cone-rod degeneration type 6 (CORD6) change RetGC1 regulation in vitro by Ca2+. In addition, we find that R838S substitution makes RetGC1 less sensitive to inhibition by retinal degeneration-3 protein (RD3)."

Financial supporters for this research include National Eye Institute, Pennsylvania Department of Health.

Our news journalists obtained a quote from the research from Salus University, "We selectively expressed human R838S RetGC1 in mouse rods and documented the decline in rod vision and rod survival. To verify that changes in rods were specifically caused by the CORD6 mutation, we used for comparison cones, which in the same mice did not express R838S RetGC1 from the transgenic construct. The R838S RetGC1 expression in rod outer segments reduced inhibition of cGMP production in the transgenic mouse retinas at the free calcium concentrations typical for dark-adapted rods. The transgenic mice demonstrated early-onset and rapidly progressed with age decline in visual responses from the targeted rods, in contrast to the longer lasting preservation of function in the non-targeted cones. The decline in rod function in the retina resulted from a progressive degeneration of rods between 1 and 6 months of age, with the severity and pace of the degeneration consistent with the extent to which the Ca2+ sensitivity of the retinal cGMP production was affected. Our study presents a new experimental model for exploring cellular mechanisms of the CORD6-related photoreceptor death."

According to the news editors, the research concluded: "This mouse model provides the first direct biochemical and physiological in vivo evidence for the Ares substitutions in RetGC1 being the culprit behind the pathogenesis of the CORD6 congenital blindness."

Researchers from San Raffaele University Hospital Detail New Studies and Findings in the Area of Takotsubo Cardiomyopathy (Takotsubo Cardiomyopathy Following Pericardiocentesis After Aortic Valve Repair and Ascending Aorta Replacement)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Heart Disorders and Diseases - Takotsubo Cardiomyopathy are presented in a new report. According to news originating from Milan, Italy, by NewsRx correspondents, research stated, "Takotsubo cardiomyopathy is a reversible cardiomyopathy, which generally develops in menopausal women and is characterized by left ventricle dysfunction with apical ballooning in the absence of coronary artery disease."

Our news journalists obtained a quote from the research from San Raffaele University Hospital, "It is often triggered by a stressful event, and its clinical presentation resembles acute anterior myocardial infarction. This condition is a rare adverse event of cardiac operations, and only a few cases are described in the literature, especially after mitral valve operations."

According to the news editors, the research concluded: "We report the case of a 69-year-old man who underwent aortic valve repair and ascending aorta replacement, followed by pericardial effusion 6 months later, requiring pericardiocentesis resulting in Takotsubo cardiomyopathy."

The news correspondents report that additional information may be obtained from I. Belluschi, San Raffaele Univ Hosp, Dept. of Cardiac Surg, Milan, Italy. Additional authors for this research include M. Cioni, S. Moriggia and O. Alfieri.

Keywords for this news article include: Milan, Italy, Europe, Cardiovascular
Diseases and Conditions, Heart Disorders and Diseases, Left Ventricular Dysfunction, Cardiac Surgical Procedures, Takotsubo Cardiomyopathy, Pericardiocentesis, Cardiomyopathies, Heart Disease, Aortic Valve, Heart Valves, Paracentesis, Angiology, Arteries, Surgery, Aorta, San Raffaele University Hospital.

Genetics - Genetics and Cancer

Researchers from Santa Chiara Hospital Detail Findings in Genetics and Cancer (Different Prognostic Roles of Tumor Suppressor Gene BAP1 in Cancer: A Systematic Review with Meta-Analysis)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Genetics - Genetics and Cancer. According to news reporting out of Trento, Italy, by NewsRx editors, research stated, "Biallelic inactivation of the tumor suppressor gene BRCA1-associated protein 1 (BAP1) has been demonstrated in several cancers, but its prognostic role has not been completely explained. We aimed to investigate the risk associated with loss of BAP1 (BAP1-) for all-cause mortality, cancer-specific mortality and recurrence of disease in subjects with cancer."

Our news journalists obtained a quote from the research from Santa Chiara Hospital, "PubMed and SCOPUS were searched from database inception until 09/15/2015 without language restrictions. Prospective studies reporting data on prognostic parameters in subjects with cancer, comparing participants with presence of BAP1 (BAP1+) vs. BAP1-were included. Data were summarized using risk ratios (RR) for number of deaths/recurrences and hazard ratios (HR) for time-dependent risk related to BAP1-adjusted for potential confounders. From 261 hits, 12 studies (including 13 cohorts) with 3,447 participants (BAP1-: n=697; BAP1+: n=2,750), with a median follow-up over 60 months, were meta-analyzed. Compared to BAP1+, BAP1-significantly increased all-cause mortality, cancer-specific mortality and risk of recurrence in all the tumor types analyzed, except for mesothelioma, in which the presence of BAP1 mutations correlates with a better prognosis. Furthermore, we demonstrated that BAP1 mutated colorectal and renal carcinomas are associated with high-tumor grading (P <0.0001), and that BAP1 mutated is more common in women than in men (P <0.0001)."

According to the news editors, the research concluded: "On the basis of our meta-analysis, we have demonstrated a peculiar role of BAP1 in influencing the prognosis in cancer. Thus, BAP1 could be considered as an important potential target for personalized medicine."

Our news journalists report that additional information may be obtained by contacting C. Luchini, Santa Chiara Hosp, Dept. of Pathol, Trento, Italy. Additional authors for this research include N. Veronese, S. Yachida, L. Cheng, A. Nottegar, B. Stubbs, M. Solmi, P. Capelli, A. Pea, M. Barbareschi, M. Fassan, L. Dwood and A. Scarpa.

Keywords for this news article include: Trento, Italy, Europe, Genetics and Cancer, Oncology, Article Review, Risk and Prevention, Genetics, Tumor Suppression, Cancer, Santa Chiara Hospital.
Researchers from Sao Paulo State University Describe Findings in Angiotensins (Overexpression of AT2R in the solitary-vagal complex improves baroreflex in the spontaneously hypertensive rat)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Angiotensins are discussed in a new report. According to news reporting out of Araraquara, Brazil, by NewsRx editors, research stated, "The aim of this study was to investigate the physiological effects of increased angiotensin II type 2 receptor (AT2R) expression in the solitary-vagal complex (nucleus of the solitary tract/dorsal motor nucleus of the vagus; NTS/DVM) on baroreflex function in non-anaesthetised normotensive (NT) and spontaneously hypertensive rats (SHR). Ten week old NT Holtzman and SHR were microinjected with either an adeno-associated virus expressing AT2R (AAV2-CBA-AT2R) or enhanced green fluorescent protein (control; AAV2-CBA-eGFP) into the NTS/DVM."

Financial supporters for this research include CNPq, FAPESP, PNPD/CAPES, NIH. Our news journalists obtained a quote from the research from Sao Paulo State University, "Baroreflex and telemetry recordings were performed on four experimental groups: 1) NT-eGFP, 2) NT-AT2R, 3) SHR-eGFP and 4) SHR-AT2R (n = 4-7/group). Following in-vivo experimental procedures, brains were harvested for gene expression analysis. Impaired bradycardia in SHR-eGFP was restored in SHR rats over-expressing AT2R in the NTS/DMV. mRNA levels of angiotensin converting enzyme decreased and angiotensin converting enzyme 2 increased in the NTS/DMV of SHR-AT2R compared to SHR-eGFP. Increased levels of pro-inflammatory cytokine mRNA levels in the SHR-eGFP group also decreased in the SHR-AT2R group. AT2R overexpression did not elicit any significant change in mean arterial pressure (MAP) in all groups from baseline to 4 weeks post viral transfection. Both SHR-eGFP and SHR-AT2R showed a significant elevation in MAP compared to the NT-eGFP and NT-AT2R groups. Increased AT2R expression within the NTS/DMV of SHR was effective at improving baroreflex function but not MAP."

According to the news editors, the research concluded: "We propose possible mediators involved in improving baroreflex are in the ANG II/ACE2 axis, suggesting a potential beneficial modulatory effect of AT2R overexpression in the NTS/DMV of neurogenic hypertensive rats."

Our news journalists report that additional information may be obtained by contacting E. Colombari, Sao Paulo State Univ, Sch Dental, Dept. of Physiol & Pathol, Araraquara, SP, Brazil. Additional authors for this research include G.F. Speretta, G.T. Blanch, H.W. Li, C. Sumners, J.V. Menani, E. Colombari and D.S.A. Colombari.
Cardiovascular Diseases and Conditions...

Researchers from Sao Paulo State University Provide Details of New Studies and Findings in the Area of Hypertension (Sodium hydrosulfide prevents hypertension and increases in vascular endothelial growth factor and soluble fms-like tyrosine ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Cardiovascular Diseases and Conditions - Hypertension. According to news originating from Sao Paulo, Brazil, by NewsRx correspondents, research stated, "Sodium hydrosulfide (NaHS) has presented antihypertensive and antioxidant effects and may reduce circulating soluble fms-like tyrosine kinase-1 (sFlt-1). We examined whether NaHS prevents maternal and fetal detrimental changes in a model of hypertension in pregnancy induced by N(G)-nitro-L-arginine methyl ester (L-NAME)."

Financial support for this research came from Fundacao de Amparo a Pesquisa do Estado de Sao Paulo.

Our news journalists obtained a quote from the research from Sao Paulo State University, "Forty pregnant rats were divided into four groups (n = 10 per group): Norm-Preg, Preg + NaHS, HTN-Preg, or HTN-Preg + NaHS. Systolic blood pressure (SBP), number of viable fetuses, litter size, pups, and placentae weights were recorded. Circulating plasma sFlt-1, vascular endothelial growth factor (VEGF), myeloperoxidase (MPO), trolox equivalent antioxidant capacity (TEAC) levels, and biochemical determinants of nitric oxide (NO) formation were assessed. SBP values were elevated in the HTN-Preg group on gestational days 16, 18, and 20. However, HTN-Preg + NaHS group presented lower SBP values on days 18 and 20. Lower number of viable fetuses and litter size were found only in HTN-Preg group compared to other. Reductions in placental weight were found in HTN-Preg and HTN-Preg + NaHS groups. Increases in fetal weight were found only in Preg + NaHS group. Increases in circulating sFlt-1 and VEGF levels were observed only in HTN-Preg group compared to other. Higher MPO and lower TEAC plasma levels were found in HTN-Preg + NaHS and HTN-Preg groups. NO was diminished in HTN-Preg animals, and NaHS treatment increased NO levels only in hypertensive pregnant animals. Treatment with NaHS prevents hypertension in pregnancy and concomitantly reduces circulating plasma sFlt-1 and VEGF levels; this correlates with improved litter size with more viable fetuses and increase in NO levels."

According to the news editors, the research concluded: "However, these beneficial effects presented no relation with oxidative stress."

For more information on this research see: Sodium hydrosulfide prevents hypertension and increases in vascular endothelial growth factor and soluble fms-like tyrosine kinase-1 in hypertensive pregnant rats. Naunyn-Schmiedebergs Archives of Pharmacology,
Researchers from Sapporo City General Hospital Discuss Findings in Nephrology (De novo proliferative glomerulonephritis with monoclonal IgG deposits of the IgG1 kappa subtype in a kidney allograft)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Health and Medicine - Nephrology have been published. According to news reporting originating in Hokkaido, Japan, by NewsRx journalists, research stated, "Proliferative glomerulonephritis with monoclonal immunoglobulin G (IgG) deposits (PGNMID) has recently been described in cases with glomerular disease. Only 16 cases of recurrent or de novo PGNMID have been reported in the transplanted kidney."

The news reporters obtained a quote from the research from Sapporo City General Hospital, "Here we report a case of de novo PGNMID in a renal allograft diagnosed in the early stage by protocol biopsy. A 41-year-old male with end-stage kidney disease caused by focal glomerular sclerosis received a living-related kidney transplant. The post-transplantation course was stable, except for an early episode of acute T cell-mediated rejection. Mesangial C1q deposition was found on the 3-year protocol biopsy. On the 4-year protocol biopsy, mild mesangioproliferative changes and deposition of IgG, C1q, C3, IgG1, and light chain were evident, confirming the diagnosis of PGNMID of the IgG1 subtype. Furthermore, mild proteinuria was detected at that time. Because a subsequent haematological examination revealed high copy number Epstein-Barr virus (EBV) DNA and free light chain in blood, the posttransplant lymphoproliferative disorder (PTLD) was suspected."

According to the news reporters, the research concluded: "Mycophenolate mofetil (MMF) was discontinued and rituximab was administered for the treatment of PTLD; subsequently, the improvement in proteinuria and serum creatinine was found 2 months after rituximab administration."

For more information on this research see: De novo proliferative glomerulonephritis with monoclonal IgG deposits of the IgG1 kappa subtype in a kidney allograft. Nephrology,
Researchers from School of Chemistry Describe Findings in Drug Delivery Systems (Profluorescent PPV-Based Micellar System as a Versatile Probe for Bioimaging and Drug Delivery)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Drugs and Therapies - Drug Delivery Systems. According to news reporting out of Sydney, Australia, by NewsRx editors, research stated, "Although micelles are commonly used for drug delivery purposes, their long-term fate is often unknown due to photobleaching of the fluorescent labels or the use of toxic materials. Here, we present a metal-free, nontoxic, nonbleaching, fluorescent micelle that can address these shortcomings."

Financial supporters for this research include Federaal Wetenschapsbeleid, Agentschap voor Innovatie door Wetenschap en Technologie.

Our news journalists obtained a quote from the research from the School of Chemistry, "A simple, yet versatile, profluorescent micellar system, built from amphiphilic poly (p-phenylenevinylene) (PPV) block copolymers, for use in drug delivery applications is introduced. Polymer micelles made from PPV show excellent stability for up to 1 year and are successfully loaded with anticancer drugs (curcumin or doxorubicin) without requiring introduction of physical or chemical cross-links. The micelles are taken up efficiently by the cells, which triggers disassembly, releasing the encapsulated material."

According to the news editors, the research concluded: "Disassembly of the micelles and drug release is conveniently monitored as fluorescence of the single polymer chains appear, which enables not only to monitor the release of the payload, but in principle also the fate of the polymer over longer periods of time."

For more information on this research see: Profluorescent PPV-Based Micellar System as a Versatile Probe for Bioimaging and Drug Delivery. *Biomacromolecules*, 2016;17 (12):4086-4094. *Biomacromolecules* can be contacted at: Amer Chemical Soc, 1155 16TH St, NW, Washington, DC 20036, USA. (American Chemical Society - www.acs.org; Biomacromolecules - www.pubs.acs.org/journal/bomaf6)

Our news journalists report that additional information may be obtained by contacting M. Stenzel, Univ New South Wales, Sch Chem, CAMD, Sydney, NSW 2052, Australia. Additional authors for this research include H.X. Lu, T. Chang, R. Mamdooh, L. Lutsen, D. Vanderzande, M. Stenzel and T. Junkers.
Researchers from School of Chemistry and Biochemistry Discuss Findings in Proteomics (Simultaneous Time-Dependent Surface-Enhanced Raman Spectroscopy, Metabolomics, and Proteomics Reveal Cancer Cell Death Mechanisms Associated with Gold Nanorod ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Proteomics. According to news reporting from Atlanta, Georgia, by NewsRx journalists, research stated, "In cancer plasmonic photothermal therapy (PPTT), plasmonic nanoparticles are used to convert light into localized heat, leading to cancer cell death. Among plasmonic nanoparticles, gold nanorods (AuNRs) with specific dimensions enabling them to absorb near-infrared laser light have been widely used."

Financial support for this research came from Division of Chemistry.

The news correspondents obtained a quote from the research from the School of Chemistry and Biochemistry, "The detailed mechanism of PPTT therapy, however, still remains poorly understood. Typically, surface-enhanced Raman spectroscopy (SERS) has been used to detect time-dependent changes in the intensity of the vibration frequencies of molecules that appear or disappear during different cellular processes. A complete proven assignment of the molecular identity of these vibrations and their biological importance has not yet been accomplished. Mass spectrometry (MS) is a powerful technique that is able to accurately identify molecules in chemical mixtures by observing their m/z values and fragmentation patterns. Here, we complemented the study of changes in SERS spectra with MS-based metabolomics and proteomics to identify the chemical species responsible for the observed changes in SERS band intensities during PPTT. We observed an increase in intensity of the bands at around 1000, 1207, and 1580 cm(-1), which were assigned in the literature to phenylalanine, albeit with dispute. Our metabolomics results showed increased levels of phenylalanine, its derivatives, and phenylalanine-containing peptides, providing evidence for more confidence in the SERS peak assignments. To better understand the mechanism of phenylalanine increase upon PPTT, we combined metabolomics and proteomics results through network analysis, which proved that phenylalanine metabolism was perturbed. Furthermore, several apoptosis pathways were activated via key proteins (e.g., HADHA and ACAT1), consistent with the proposed role of altered phenylalanine metabolism in inducing apoptosis."

According to the news reporters, the research concluded: "Our study shows that the integration of the SERS with MS-based metabolomics and proteomics can assist the assignment of signals in SERS spectra and further characterize the related molecular mechanisms of the cellular processes involved in PPTT."

**Drugs and Therapies - Codeine Therapy**

**Researchers from School of Health Sciences Describe Findings in Codeine Therapy (Best Practices and Innovations for Managing Codeine Misuse and Dependence)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Drugs and Therapies - Codeine Therapy have been published. According to news reporting originating from Waterford, Ireland, by NewsRx correspondents, research stated, "Promoting and ensuring safe use of codeine containing medicines remains a public health issue given the rise in reporting of misuse and dependence particularly in countries where available overthe-counter (OTC). The aim of this unique study was to identify best practices in management of opioid abuse and dependence, particularly codeine, and innovations to meet challenges surrounding safe and compliant use, patient awareness-raising, reducing health harms and enhancing successful treatment of dependence."

Our news editors obtained a quote from the research from the School of Health Sciences, "A mixed methods approach using three data points was used that included: (1) analysis of data from existing scoping reviews to identify potential areas for innovation (2) interviews with key national stakeholders from public health, pharmaceutical, regulatory, primary care and addiction practice in three distinct regulatory regimes (Ireland, United Kingdom and South Africa); and (3) a circular email request for information on potential innovations to members of the European Medicine's Agency European Network of Centres for Pharmacoepidemiology and Pharmacovigilance (ENCEPP). Data from these three sources were analysed to identify best practices and opportunities for innovation. Best practices and potential innovations were identified under the nine headings: (1) manufacture; (2) product information and public education; (3) responsible prescribing; (4) monitoring and surveillance; (5) dispensing, screening and brief interventions in community pharmacies; (6) safety in the workplace and on the road; (7) internet supply of codeine and online support; (8) treatment of codeine dependence; and (9) learning resources and training for health professionals. Challenges
ensuring availability of codeine containing medicines for legitimate therapeutic use, while minimising misuse, dependence and related health harms warrant consideration of new innovations."

According to the news editors, the research concluded: "Most promising innovative potential lies across the products' retail lifecycle from manufacture to prescriber and community pharmacy practitioner."

The news editors report that additional information may be obtained by contacting M.C. Van Hout, Waterford Inst Technol, Sch Hlth Sci, Waterford, Ireland. Additional authors for this research include M. Bergin, C.D. Parry and M.C. Van Hout.

**Query Fever**

**Researchers from School of Medical Sciences Provide Details of New Studies and Findings in the Area of Query Fever (The natural history of acute Q fever: a prospective Australian cohort)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Query Fever. According to news reporting from Sydney, Australia, by NewsRx journalists, research stated, "A detailed description of the natural history of acute Q fever, caused by infection with Coxiella burnetii. Aim: To significantly increase understanding of the illness. Subjects with provisional acute Q fever (n = 115) were recruited from primary care in rural Australia, and followed prospectively by interview and blood collection including for serological confirmation."

The news correspondents obtained a quote from the researchers from the School of Medical Sciences, "A nested series of subjects with prolonged illness (cases), and those without (controls), were investigated in detail. Total phase I and phase II anti-C. burnetii antibodies were detected by complement fixation test; and IgG, IgM and IgA phase I and phase II titres by immunofluorescence. Flow cytometric analysis was conducted to enumerate circulating T cells subsets, B cells, monocytes and natural killer cells. Serological testing confirmed acute Q fever in 73 subjects (63%). The acute illness featured fever, headache, sweats, fatigue and anorexia; and varied widely in severity, causing an average of 8 days in bed and 15 days out of work or other role in the first month of illness. The illness course varied from 2 days to greater than a year. No cases of chronic, localized Q fever infection, such as endocarditis, were identified. Neither severe nor prolonged illness were associated with persistence of C. burnetii DNA, altered patterns of C. burnetii-specific IgG, IgM or IgA antibody production, or altered leucocyte subsets. The severity of acute Q fever alone predicted prolonged duration."

According to the news reporters, the research concluded: "Further studies are
warranted to better understand the pathophysiology of prolonged illness after acute Q fever."

Our news journalists report that additional information may be obtained by contacting B. Cameron, Univ New South Wales, Sch Med Sci, Sydney, NSW, Australia. **Drugs and Therapies - Coagulation Modifiers**

**Researchers from School of Medicine Describe Findings in Coagulation Modifiers (Methods to decrease blood loss during liver resection: a network meta-analysis)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Drugs and Therapies - Coagulation Modifiers are discussed in a new report. According to news reporting from London, United Kingdom, by NewsRx journalists, research stated, "Liver resection is a major surgery with significant mortality and morbidity. Specialists have tested various methods in attempts to limit blood loss, transfusion requirements, and morbidity during elective liver resection."

The news correspondents obtained a quote from the research from the School of Medicine, "These methods include different approaches (anterior versus conventional approach), use of autologous blood donation, cardiopulmonary interventions such as hypoventilation, low central venous pressure, different methods of parenchymal transection, different methods of management of the raw surface of the liver, different methods of vascular occlusion, and different pharmacological interventions. A surgeon typically uses only one of the methods from each of these seven categories. The optimal method to decrease blood loss and transfusion requirements in people undergoing liver resection is unknown. To assess the effects of different interventions for decreasing blood loss and blood transfusion requirements during elective liver resection. Search methods We searched the Cochrane Central Register of Controlled Trials (CENTRAL), MEDLINE, Embase, and Science Citation Index Expanded to September 2015 to identify randomised clinical trials. We also searched trial registers and handsearched the references lists of identified trials. Selection criteria We included only randomised clinical trials (irrespective of language, blinding, or publication status) comparing different methods of decreasing blood loss and blood transfusion requirements in people undergoing liver resection. Data collection and analysis Two review authors independently identified trials and collected data. We assessed the risk of bias using Cochrane domains. We
conducted a Bayesian network meta-analysis using the Markov chain Monte Carlo method in WinBUGS 1.4, following the guidelines of the National Institute for Health and Care Excellence Decision Support Unit guidance documents. We calculated the odds ratios (OR) with 95% credible intervals (CrI) for the binary outcomes, mean differences (MD) with 95% CrI for continuous outcomes, and rate ratios with 95% CrI for count outcomes, using a fixed-effect model or random-effects model according to model-fit. We assessed the evidence with GRADE. We identified 67 randomised clinical trials involving a total of 6197 participants. All the trials were at high risk of bias. A total of 5771 participants from 64 trials provided data for one or more outcomes included in this review. There was no evidence of differences in most of the comparisons, and where there was, these differences were in single trials, mostly of small sample size. We summarise only the evidence that was available in more than one trial below. Of the primary outcomes, the only one with evidence of a difference from more than one trial under the pair-wise comparison was in the number of adverse events (complications), which was higher with radiofrequency dissecting sealer than with the clamp-crush method (rate ratio 1.85, 95% CrI 1.07 to 3.26; 250 participants; 3 studies; very low-quality evidence). Among the secondary outcomes, the only differences we found from more than one trial under the pair-wise comparison were the following: blood transfusion (proportion) was higher in the low central venous pressure group than in the acute normovolemic haemodilution plus low central venous pressure group (OR 3.19, 95% CrI 1.56 to 6.95; 208 participants; 2 studies; low-quality evidence); blood transfusion quantity (red blood cells) was lower in the fibrin sealant group than in the control (MD -0.53 units, 95% CrI -1.00 to -0.07; 122 participants; 2; very low-quality evidence); blood transfusion quantity (fresh frozen plasma) was higher in the oxidised cellulose group than in the fibrin sealant group (MD 0.53 units, 95% CrI 0.36 to 0.71; 80 participants; 2 studies; very low-quality evidence); blood loss (MD -0.34 L, 95% CrI -0.46 to -0.22; 237 participants; 4 studies; very low-quality evidence), total hospital stay (MD -2.42 days, 95% CrI -3.91 to -0.94; 197 participants; 3 studies; very low-quality evidence), and operating time (MD -15.32 minutes, 95% CrI -29.03 to -1.69; 192 participants; 4 studies; very low-quality evidence) were lower with low central venous pressure than with control. For the other comparisons, the evidence for difference was either based on single small trials or there was no evidence of differences. None of the trials reported health-related quality of life or time needed to return to work. Authors' conclusions Paucity of data meant that we could not assess transitivity assumptions and inconsistency for most analyses. When direct and indirect comparisons were available, network meta-analysis provided additional effect estimates for comparisons where there were no direct comparisons. However, the paucity of data decreases the confidence in the results of the network meta-analysis. Low-quality evidence suggests that liver resection using a radiofrequency dissecting sealer may be associated with more adverse events than with the clamp-crush method. Low-quality evidence also suggests that the proportion of people requiring a blood transfusion is higher with low central venous pressure than with acute normovolemic haemodilution plus low central venous pressure; very low-quality evidence suggests that blood transfusion quantity (red blood cells) was lower with fibrin sealant than control; blood transfusion quantity (fresh frozen plasma) was higher with oxidised cellulose than with fibrin sealant; and blood loss, total hospital stay, and operating time were lower with low central venous pressure than with control. There is no evidence to suggest that using special equipment for liver resection is of any benefit in decreasing the mortality, morbidity, or blood transfusion requirements (very low-quality evidence). Radiofrequency dissecting sealer should not be used outside the clinical trial setting since there is low-quality evidence for increased harm without any evidence of benefits."

According to the news reporters, the research concluded: "In addition, it should be noted that the sample size was small and the credible intervals were wide, and we cannot rule
Researchers from School of Medicine Report New Studies and Findings in the Area of Gastroenterology (Bisphosphonates as potential adjuvants for patients with cancers of the digestive system)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Health and Medicine - Gastroenterology. According to news reporting from New York City, New York, by NewsRx journalists, research stated, "Best known for their anti-resorptive activity in bone, bisphosphonates (BPs) have generated interest as potential antineoplastic agents given their pleiotropic biological effects which include antiproliferative, antiangiogenic and immune-modulating properties. Clinical studies in multiple malignancies suggest that BPs may be active in the prevention or treatment of cancer."

The news correspondents obtained a quote from the research from the School of Medicine, "Digestive tract malignancies represent a large and heterogeneous disease group, and the activity of BPs in these cancers has not been extensively studied. Recent data showing that some BPs inhibit human epidermal growth factor receptor (HER) signaling highlight a potential therapeutic opportunity in digestive cancers, many of which have alterations in the HER axis."

According to the news reporters, the research concluded: "Herein, we review the available evidence providing a rationale for the repurposing of BPs as a therapeutic adjunct in the treatment of digestive malignancies, especially in HER-driven subgroups."

Our news journalists report that additional information may be obtained by contacting C. Ang, Celina Ang, Dept. of Medicine, Division of Hematology, Oncology, Icahn
Researchers from School of Pharmaceutical Science Detail Findings in Gastric Cancer (Auranofin induces apoptosis by ROS-mediated ER stress and mitochondrial dysfunction and displayed synergistic lethality with piperlongumine in gastric cancer)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Oncology - Gastric Cancer are presented in a new report. According to news reporting from Zhejiang, People's Republic of China, by NewsRx journalists, research stated, "Gastric cancer (GC) is one of the leading causes of cancer mortality in the world. In addressing the need of treatments for relapsed disease, we report the identification of an existing U.S.

The news correspondents obtained a quote from the research from the School of Pharmaceutical Science, "Food and Drug Administration-approved small-molecule drug to repurpose for GC treatment. Auranofin (AF), clinically used to treat rheumatic arthritis, but it exhibited preclinical efficacy in GC cells. By increasing intracellular reactive oxygen species (ROS) levels, AF induces a lethal endoplasmic reticulum stress response and mitochondrial dysfunction in cultured GC cells. Blockage of ROS production reversed AF-induced ER stress and mitochondrial pathways activation as well as apoptosis. In addition, AF displays synergistic lethality with an ROS-generating agent piperlongumine, which is a natural product isolated from the long pepper Piper longum L. Taken together, this work provides a novel anticancer candidate for the treatment of gastric cancer."

According to the news reporters, the research concluded: "More importantly, it reveals that increased ROS generation might be an effective strategy in treating human gastric cancer."

For more information on this research see: Auranofin induces apoptosis by ROS-mediated ER stress and mitochondrial dysfunction and displayed synergistic lethality with piperlongumine in gastric cancer. Oncotarget, 2015;6(34):36505-21.

Researchers from School of Psychiatry Describe Findings in Bipolar Disorders (Study design and methodology for a multicentre, randomised controlled trial of transcranial direct current stimulation as a treatment for unipolar and bipolar ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Mental Health Diseases and Conditions - Bipolar Disorders are discussed in a new report. According to news reporting originating in Sydney, Australia, by NewsRx journalists, research stated, "Transcranial Direct Current Stimulation (tDCS) is a new, non-invasive neuromodulation approach for treating depression that has shown promising efficacy. The aim of this trial was to conduct the first international, multicentre randomised controlled trial of tDCS as a treatment for unipolar and bipolar depression."

Financial support for this research came from Stanley Medical Research Institute.

The news reporters obtained a quote from the research from the School of Psychiatry, "The study recruited 120 participants across 6 sites in the USA and Australia. Participants received active or sham tDCS (2.5 mA, 20 sessions of 30 min duration over 4 weeks), followed by a 4-week open label active treatment phase and a 4-week taper phase. Mood and neuropsychological outcomes were assessed with the primary antidepressant outcome measure being the Montgomery-Asberg Depression Rating Scale (MADRS). A neuropsychological battery was administered to assess safety and examine cognitive effects. The study also investigated the possible influence of genetic polymorphisms on outcomes. The trial was triple-blinded. tDCS treaters and study raters were blinded to each participant's tDCS group allocation in the sham-controlled phase. Specific aspects of tDCS administration, device operation and group allocation were designed to optimise the integrity of blinding. Outcome measures will be tested using a mixed effects repeated measures analysis with the primary factors being Time as a repeated measure, tDCS condition (sham or active) and Diagnosis (unipolar or bipolar). A restricted number of random and fixed factors will be included as required to account for extraneous differences."

According to the news reporters, the research concluded: "As a promising treatment, tDCS has excellent potential for translation into widespread clinical use, being cost effective, portable, easy to operate and well tolerated."

For more information on this research see: Study design and methodology for a multicentre, randomised controlled trial of transcranial direct current stimulation as a treatment for unipolar and bipolar depression. *Contemporary Clinical Trials*, 2016;51():65-71. *Contemporary Clinical Trials* can be contacted at: Elsevier Science Inc, 360 Park Ave South, New York, NY 10010-1710, USA. (Elsevier - www.elsevier.com; Contemporary Clinical Trials - www.journals.elsevier.com/contemporary-clinical-trials/)

Our news correspondents report that additional information may be obtained by
Researchers from Scripps Research Institute Report Details of New Studies and Findings in the Area of HIV/AIDS (Potent and Targeted Activation of Latent HIV-1 Using the CRISPR/dCas9 Activator Complex)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Immune System Diseases and Conditions - HIV/AIDS have been published. According to news reporting from La Jolla, California, by NewsRx journalists, research stated, "HIV-1 provirus integration results in a persistent latently infected reservoir that is recalcitrant to combined antiretroviral therapy (cART) with lifelong treatment being the only option. The 'shock and kill' strategy aims to eradicate latent HIV by reactivating proviral gene expression in the context of cART treatment."

The news correspondents obtained a quote from the research from Scripps Research Institute, "Gene-specific transcriptional activation can be achieved using the RNA-guided CRISPR-Cas9 system comprising single guide RNAs (sgRNAs) with a nuclease-deficient Cas9 mutant (dCas9) fused to the VP64 transactivation domain (dCas9-VP64). We engineered this system to target 23 sites within the long terminal repeat promoter of HIV-1 and identified a 'hotspot' for activation within the viral enhancer sequence. Activating sgRNAs transcriptionally modulated the latent proviral genome across multiple different in vitro latency cell models including T cells comprising a clonally integrated mCherry-IRES-Tat (LChIT) latency system. We detected consistent and effective activation of latent virus mediated by activator sgRNAs, whereas latency reversal agents produced variable activation responses. Transcriptomic analysis revealed dCas9-VP64/sgRNAs to be highly specific, while the well-characterized chemical activator TNFa induced widespread gene dysregulation."

According to the news reporters, the research concluded: "CRISPR-mediated gene activation represents a novel system which provides enhanced efficiency and specificity in a targeted latency reactivation strategy and represents a promising approach to a 'functional cure' of HIV/AIDS."

For more information on this research see: Potent and Targeted Activation of Latent HIV-1 Using the CRISPR/dCas9 Activator Complex. Molecular Therapy, 2015;24(3):488-98. (Elsevier - www.elsevier.com; Molecular Therapy - www.journals.elsevier.com/molecular-therapy/)
Researchers from Second Military Medical University Discuss Findings in Immunotherapy (Antitumor Activity of cGAMP via Stimulation of cGAS-cGAMP-STING-IRF3 Mediated Innate Immune Response)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Drugs and Therapies - Immunotherapy is now available. According to news reporting out of Shanghai, People's Republic of China, by NewsRx editors, research stated, "Immunotherapy is one of the key strategies for cancer treatment. The cGAS-cGAMP-STING-IRF3 pathway of cytosolic DNA sensing plays a pivotal role in antiviral defense."

Our news journalists obtained a quote from the research from Second Military Medical University, "We report that the STING activator cGAMP possesses significant antitumor activity in mice by triggering the STING-dependent pathway directly. cGAMP enhances innate immune responses by inducing production of cytokines such as interferon-b, interferon-g, and stimulating dendritic cells activation, which induces the cross-priming of CD8 (+) T cells. The antitumor mechanism of cGAMP was verified by STING and IRF3, which were up-regulated upon cGAMP treatment. STING-deficiency dramatically reduced the antitumor effect of cGAMP. Furthermore, cGAMP improved the antitumor activity of 5-FU, and clearly reduced the toxicity of 5-FU."

According to the news editors, the research concluded: "These results demonstrated that cGAMP is a novel antitumor agent and has potential applications in cancer immunotherapy."

For more information on this research see: Antitumor Activity of cGAMP via Stimulation of cGAS-cGAMP-STING-IRF3 Mediated Innate Immune Response. Scientific Reports, 2016;6():19049. (Nature Publishing Group - www.nature.com/; Scientific Reports - www.nature.com/srep/)

Our news journalists report that additional information may be obtained by contacting T. Li, Dept. of Pharmacology, School of Pharmacy, Second Military Medical University, Shanghai, 200433, People's Republic of China. Additional authors for this research include H. Cheng, H. Yuan, Q. Cardiology

Researchers from Semmelweis University Report Recent Findings in Cardiology (Fracture and Lung Penetration of a Left Ventricular Lead Stabilized by Retained Stylet)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Cardiology are presented in a new report. According to news reporting out of Budapest, Hungary, by NewsRx editors, research stated, "During cardiac resynchronization therapy (CRT) pacemaker implantation in a 54-year-old female patient, removing the stylet resulted in repeated left ventricular (LV) lead dislodgment. Lead stability was achieved by retaining the stylet within the lead lumen."

Our news journalists obtained a quote from the research from Semmelweis University, "Two years after cardiac resynchronization therapy, a LV lead fracture near the connector pin occurred. The proximal lead segment was removed, and a new connector pin was attached. Two years after that, the same lead fractured in the right atrium with the stylet penetrating the lung. The LV lead and retained stylet were successfully extracted."

According to the news editors, the research concluded: "LV lead dislodgment is a limitation of CRT, but using the retained stylet technique to achieve lead stability is potentially dangerous and is not recommended."

Our news journalists report that additional information may be obtained by contacting B. Merkely, Semmelweis University, Center Heart, H-1122 Budapest, Hungary. Additional authors for this research include G. Duray, K. Huttl and B. Merkely.

Researchers from Seoul National University Report Findings in Aldehydes (Cystathionine metabolic enzymes play a role in the inflammation resolution of human keratinocytes in response to sub-cytotoxic formaldehyde exposure)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Aldehydes is the subject of a report. According to news reporting out of Seoul, South Korea, by NewsRx editors, research stated, "Low-level formaldehyde exposure is inevitable in industrialized countries. Although daily-life formaldehyde exposure level is practically impossible to induce cell death, most of mechanistic studies related to formaldehyde toxicity have been performed in cytotoxic concentrations enough to trigger cell death mechanism."

Funders for this research include National Research Foundation of Korea, Korea Healthcare Technology R&D Project, Ministry of Health & Welfare, Seoul National University.

Our news journalists obtained a quote from the research from Seoul National University, "Currently, toxicological mechanisms underlying the sub-cytotoxic exposure to formaldehyde are not clearly elucidated in skin cells. In this study, the genome-scale transcriptional analysis in normal human keratinocytes (NHKs) was performed to investigate cutaneous biological pathways associated with daily life formaldehyde exposure. We selected the 175 upregulated differentially expressed genes (DEGs) and 116 downregulated DEGs in NHKs treated with 200 mu M formaldehyde. In the Gene Ontology (GO) enrichment analysis of the 175 upregulated DEGs, the endoplasmic reticulum (ER) unfolded protein response (UPR) was identified as the most significant GO biological process in the formaldehyde-treated NHKs. Interestingly, the sub-cytotoxic formaldehyde affected NHKs to upregulate two enzymes important in the cellular transsulfuration pathway, cystathionine gamma-lyase (CTH) and cystathionine-beta-synthase (CBS). In the temporal expression analysis, the upregulation of the pro-inflammatory DEGs such as MMP1 and PTGS2 was detected earlier than that of CTH, CBS and other ER UPR genes. The metabolites of CTH and CBS, L-cystathionine and L-cysteine, attenuated the formaldehyde-induced upregulation of pro-inflammatory DEGs, MMP1, PTGS2, and CXCL8, suggesting that CTH and CBS play a role in the negative feedback regulation of formaldehyde-induced pro-inflammatory responses in NHKs."

According to the news editors, the research concluded: "In this regard, the sub-cytotoxic formaldehyde-induced CBS and CTH may regulate inflammation fate decision to resolution by suppressing the early pro-inflammatory response."

For more information on this research see: Cystathionine metabolic enzymes play a role in the inflammation resolution of human keratinocytes in response to sub-cytotoxic formaldehyde exposure. Toxicology and Applied Pharmacology, 2016;310();185-194. Toxicology and Applied Pharmacology can be contacted at: Academic Press Inc Elsevier Science, 525 B St, Ste 1900, San Diego, CA 92101-4495, USA. (Elsevier - www.elsevier.com; Toxicology and Applied Pharmacology - www.journals.elsevier.com/toxicology-and-applied-pharmacology/)

Researchers from Shaheed Beheshti University of Medical Sciences Report Details of New Studies and Findings in the Area of Breast Cancer (Breast cancer classification and prognostication through diverse systems along with recent emerging ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Oncology - Breast Cancer have been published. According to news reporting originating from Tehran, Iran, by NewsRx correspondents, research stated, "Breast cancer is the most common malignancy among women and the second leading cause of mortality due to cancer worldwide. The complexity of breast cancer resembles an intricate ecosystem comprising various cleverly designed interaction levels of internal and external factors to generate a pliable context in the clonal evolution of breast cancer cells."

Our news editors obtained a quote from the research from the Shaheed Beheshti University of Medical Sciences, "Principally, the complex entity can become evident toward delineating a number of significant variations in the specific fields of breast cancer analyses, including the molecular, physiological, and morphological characteristics, clinical presentations, risk factors, the histopathological conditions, and response to systemic therapy regarding the maintenance of tumor as a whole. In hindsight, various classification systems developing based on specific inclusion criteria have indisputably changed both our appreciation of the biological demeanor of breast cancer and the main strategies for designing tailored therapy regimens through the proper evaluation of diagnosis and prognostication of given specimens. Here, we endeavor to provide a general overview of different types of breast cancer classification as well as the clinical acceptance of their applications along with the latest findings in this area."

According to the news editors, the research concluded: "Taken together, the major significance of breast cancer management that can be ascertained by operational convergent points of its stratification areas is owing to the fact that the achievement of individualized and targeted therapy may denounce new horizons of surveillance and treatment strategies in which they may function as a rheostat of specific therapy regimens toward reducing the detected distances between experimental data and operating options in clinical practice."

For more information on this research see: Breast cancer classification and prognostication through diverse systems along with recent emerging findings in this respect; the dawn of new perspectives in the clinical applications. Tumor Biology, 2016;37(11):14479-14499. Tumor Biology can be contacted at: Springer, Van Godewijckstraat 30, 3311 Gz Dordrecht, Netherlands. Drugs and Therapies - Antibiotics

Researchers from Shandong University Detail Findings in Antibiotics (A bicyclo-hairpin probe mediated strand displacement amplification strategy for label-free and sensitive detection of bleomycin)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Drugs and Therapies - Antibiotics. According to news reporting originating from Jinan, People's Republic of China, by NewsRx correspondents, research stated, "Monitoring of bleomycin concentration is critical in clinical therapy. Here, a bicyclo-hairpin probe mediated strand displacement amplification strategy was developed for bleomycin detection."

Financial support for this research came from National Natural Sciences Foundation of China.

Our news editors obtained a quote from the research from Shandong University, "Firstly, bleomycin cleaved bicyclo-hairpin probe to release a trigger sequence. Then the trigger sequence initiated strand displacement amplification reaction to produce numerous G-quadruplex forming sequences. Finally, G-quadruplexes bound with N-methyl mesoporphyrin IX molecules and an enhanced fluorescent signal could be detected. In this strategy, a bicyclo-hairpin probe was ingeniously designed for bleomycin detection, which could silence the trigger sequence to reduce non-specific hybridization of detection method. In addition, based on bleomycin-induced DNA scission, a label-free fluorescent sensor for bleomycin detection was established. Our strategy could determine bleomycin sensitively with a detection limit of 0.34 nM. Fluorescent response of detection system toward four different anti-tumor drugs proved that this strategy had admirable selectivity."

According to the news editors, the research concluded: "Satisfactory recoveries in human serum samples revealed that our method had a great potential in real sample assay."

For more information on this research see: A bicyclo-hairpin probe mediated strand displacement amplification strategy for label-free and sensitive detection of bleomycin. Sensors and Actuators B-Chemical, 2017;238():318-324. Sensors and Actuators B-Chemical can be contacted at: Elsevier Science Sa, PO Box 564, 1001 Lausanne, Switzerland.

Biotechnology - Xenografts

Researchers from Shanghai Jiao-Tong University Provide Details of New Studies and Findings in the Area of Xenografts (The Marine-Derived Oligosaccharide Sulfate MS80, a Novel Transforming Growth Factor beta 1 Inhibitor, Reverses Epithelial ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Biotechnology - Xenografts. According to news originating from Shanghai, People's Republic of China, by NewsRx correspondents, research stated, "Metastasis accounts for the majority of cancer-related deaths. Transforming growth factor beta (TGF-beta) is believed to promote late-stage cancer progression and metastasis by inducing epithelial-mesenchymal transition (EMT)."

Our news journalists obtained a quote from the research from Shanghai Jiao-Tong University, "We previously reported that MS80, a novel oligosaccharide sulfate, inhibits TGF-beta 1-induced pulmonary fibrosis by binding TGF-beta 1. In our study MS80 effectively inhibited TGF-beta/Smad signaling in lung cancer cells, breast cancer cells, and model cell lines. In addition, MS80 inhibited TGF-beta 1-induced EMT, motility, and invasion in vitro. Moreover, MS80 significantly inhibited lung metastasis in orthotopic 4T1 xenografts. Notably, the MS80 treatment significantly increased the infiltration of CD8(+) T cells and decreased the infiltration of regulatory T cells in primary tumors and spleens in mice bearing 4T1 xenografts."

According to the news editors, the research concluded: "Therefore, MS80 is a novel and promising candidate for treating metastatic malignancies by targeting TGF-beta 1-induced EMT and mediating immunosuppression."

For more information on this research see: The Marine-Derived Oligosaccharide Sulfate MS80, a Novel Transforming Growth Factor beta 1 Inhibitor, Reverses Epithelial Mesenchymal Transition Induced by Transforming Growth Factor-beta 1 and Suppresses Tumor Metastasis. Journal of Pharmacology and Experimental Therapeutics, 2016;359(1):54-61. Journal of Pharmacology and Experimental Therapeutics can be contacted at: Amer Soc Pharmacology Experimental Therapeutics, 9650 Rockville Pike, Bethesda, MD 20814-3995, USA.

Researchers from Shanghai Jiao-Tong University Report Findings in Liver Cancer (NRBP2 Overexpression Increases the Chemosensitivity of Hepatocellular Carcinoma Cells via Akt Signaling)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Oncology - Liver Cancer is the subject of a report. According to news reporting from Shanghai, People's Republic of China, by NewsRx journalists, research stated, "Hepatocellular carcinoma is highly resistant to chemotherapy. Research data supported that cancer stem cells (CSC) may be responsible for the chemoresistance and strategies that suppress CSCs stemness could also inhibit the drug resistance."

The news correspondents obtained a quote from the research from Shanghai Jiao-Tong University, "In this study, we found that nuclear receptor binding protein 2 (NRBP2) expression was downregulated in the CD133(+) hepatocellular carcinoma CSCs. Most adjacent noncancerous liver tissue analyzed expressed higher level of NRBP2 compared with cancerous tissue in hepatocellular carcinoma patients, and high NRBP2 expression indicated a better prognosis. Real-time PCR results showed that NRBP2 negatively correlated with stemness-related genes, including Oct3/4, Nanog, Notch1, Ep300, and CD133 mRNA expression. High NRBP2 expression in hepatocellular carcinoma cells downregulated CK19 protein expression, inhibited tumor-sphere formation, and tumorigenesis ability, indicating that high NRBP2 expression restrains the hepatocellular carcinoma cell stemness. Overexpression of NRBP2 reduced the IC50 of sorafenib in hepatocellular carcinoma cells, and NRBP2 expression was negatively correlated with hepatocellular carcinoma cell resistance to the chemotherapy agents, including cisplatin and the Akt signaling inhibitor perifosine. Coimmunoprecipitation results showed that NRBP2 could bind with Annexin A2 (ANXA2) and inhibit ANXA2 expression. Coexpression of ANXA2 restored the chemoresistant ability in NRBP2-overexpressing hepatocellular carcinoma cells. Further analysis showed that NRBP2 downregulated Akt and its downstream signaling target Bad phosphorylation level. ANXA2 coexpression partially restored the Akt phosphorylation. Analysis of the expression of Bcl2 family proteins showed that NRBP2 may increase hepatocellular carcinoma cell chemosensitivity by regulating expression of survival proteins involved in the Akt and Bcl2 pathway."

According to the news reporters, the research concluded: "These results suggest that NRBP2 plays an important role in the tumor progression and chemotherapeutic resistance of hepatocellular carcinoma."

For more information on this research see: NRBP2 Overexpression Increases the Chemosensitivity of Hepatocellular Carcinoma Cells via Akt Signaling. Cancer Research, 2016;76(23):7059-7071. Cancer Research can be contacted at: Amer Assoc Cancer Research, 615 Chestnut St, 17TH Floor, Philadelphia, PA 19106-4404, USA. Researchers from Shanghai University Report Details of New Studies and Findings in the Area of Lung Cancer (Panax notoginseng saponins attenuate lung cancer growth in part through modulating the level of Met/miR-222 axis)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Oncology - Lung Cancer are discussed in a new report. According to news reporting originating in Shanghai, People's Republic of China, by NewsRx journalists, research stated, "Ethnopharmacological relevance: Panax notoginseng saponins (PNS) are the major chemical constituents of Panax notoginseng (Burkill) F.H. Chen (Araliaceae), a medicinal herb extensively used in China for the treatment of various diseases including cancer."

Financial supporters for this research include Shanghai Institutions of Higher Learning, National Natural Science Foundation of China.

The news reporters obtained a quote from the research from Shanghai University, "PNS have been reported to contribute to the therapeutic effects of Panax notoginseng in disease conditions including lung cancer. Aim of the study: The current study aims to further understand the molecular mechanisms implicated in the pharmacological activities of PNS in attenuating lung cancer growth. Lewis lung carcinoma (LLC) cell line was employed and the impact of PNS treatment on the viability of LLC cells was first examined in vitro. The tumor-suppressive effect of PNS was further validated in vivo by assessing the tumor growth in BALB/c mice inoculated with LLC cells. Whole genome microarray and real-time PCR analyses were performed to examine and verify altered expression of genes associated with PNS treatment. Real-time PCR and western blotting analyses were also carried out to investigate the implication of microRNA (miRNA)-mediated gene expression regulation in the anti-tumor activity of PNS. PNS treatment resulted in selective impairment of the survival of LLC cells. Furthermore, PNS treatment led to attenuated growth of tumors derived from inoculated LLC cells in mice. Bioinformatic analyses of gene expression profiles revealed that multiple pathways associated with tumorigenesis were significantly modulated by PNS treatment in vivo. The expression of an array of genes promoting tumorigenesis and progression including Hgf, Met, Notch3, Scd1, Epas1, Colla1, Raf1, Braf1 and CDK6 was significantly decreased by PNS treatment, whereas the expression of tumor suppressive Rxrg was significantly increased as a result of PNS treatment. The level of miR-222, a miRNA regulated by Met, was significantly decreased by PNS treatment. The expression of tumor suppressor p27 and PTEN, miR-222 target genes, was significantly
increased by PNS treatment. Our work here presented novel evidence demonstrating that multiple mechanisms were implicated in the anti-tumor effects of PNS in lung cancer models. Particularly, PNS treatment significantly modulated the level of Met/miR-222 axis in LLC cells."

According to the news reporters, the research concluded: "Increased understanding of the antitumor mechanisms of PNS may provide further experimental evidence to help optimize the therapeutic modalities for the treatment of lung cancer and other types of cancer."

**Science - Food Science**

**Researchers from Shanxi University Discuss Findings in Food Science (Resveratrol Induces Cancer Cell Apoptosis through MiR-326/PKM2-Mediated ER Stress and Mitochondrial Fission)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Science - Food Science are presented in a new report. According to news originating from Taiyuan, People's Republic of China, by NewsRx correspondents, research stated, "Resveratrol (Res), a natural phytoalexin found in a variety of plants, has significant antitumor activity. Pyruvate kinase M2 (PKM2) has abnormally high expression in various tumor cells, and it has been implicated in the survival of tumors."

Funders for this research include National Natural Science Foundation of China, Natural Science Foundation of Zhejiang Province, Science Foundation for Outstanding Youths of Shanxi Province, Higher Education Institutions of Shanxi Province, Shanxi Province.

Our news journalists obtained a quote from the research from Shanxi University, "However, whether and how Res inhibits PKM2 expression is poorly understood. In the present study, we found that treatment with Res inhibited cell proliferation and induced cell apoptosis. The IC50 values of Res against DLD1, HeLa, and MCF-7 cells were 75 +/- 4.54, 50 +/- 3.65, and 50 +/- 3.32 mu M, respectively. To elucidate mechanisms underlying its antitumor activities, serial experiments were performed. Results showed that reduction of PKM2
expression in tumor cells by Res treatment increased the expression of ER stress and mitochondrial fission proteins but reduced cell viability and the levels of fusion proteins. These phenomena were reversed by artificial overexpression of PKM2. Quantitative analyses showed that the expression of microRNA-326 (miR-326) was increased upon Res treatment. Treatment with the miR-326 mimic reduced PKM2 expression, promoting recovery from ER stress and mitochondrial fission. Overall, these results demonstrate that miR-326/PKM2-mediated ER stress and mitochondrial dysfunction participate in apoptosis induced by Res."

According to the news editors, the research concluded: "These results provide novel insight into the molecular mechanisms by which Res suppresses tumors and further support for the use of Res as an antitumor drug."

The news correspondents report that additional information may be obtained from Z.Y. Li, Shanxi Univ, Inst Biomed Sci, Taiyuan 030006, People's Republic of China. Additional authors for this research include Y.Y. Wang, C.X. Wu, P. Yang, H.Q. Li and Z.Y. Li.

Musculoskeletal Diseases and Conditions - Osteolysis

Researchers from Shaoxing University Report Details of New Studies and Findings in the Area of Osteolysis (Puerarin Prevents LPS-Induced Osteoclast Formation and Bone Loss via Inhibition of Akt Activation)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Musculoskeletal Diseases and Conditions - Osteolysis are discussed in a new report. According to news originating from Shaoxing, People's Republic of China, by NewsRx correspondents, research stated, "Osteolysis induced by chronic Gram-negative bacterial infection underlies many bone diseases such as osteomyelitis, septic arthritis, and periodontitis. Drugs that inhibit lipopolysaccharide (LPS)-induced osteolysis are critically needed for the prevention of bone destruction in infective bone diseases."

Our news journalists obtained a quote from the research from Shaoxing University, "In this study, we assessed the effect of puerarin, a natural isoflavone isolated from Pueraria lobata OHWI root, on LPS-induced osteoclastogenesis and bone loss. Our in vitro study showed that puerarin significantly inhibited LPS-induced osteoclast differentiation from osteoclast precursor RAW264.7 cells. The inhibition occurred through suppressing the production of osteoclast activating factor tumor necrosis factor (TNF)-alpha, interleukin (IL)-1 beta and prostaglandin E-2 (PGE(2)), which led to down-regulating mRNA expression of
osteoclastogenic genes including tartrate-resistant acid phosphatase (TRAP), cathepsin K and matrix metalloprotein 9 (MMP-9). Furthermore, LPS triggered activation of Akt in osteoclast precursor RAW264.7 cells, which was inhibited by puerarin treatment. In vivo, puerarin attenuated LPS-induced bone loss in a murine calvarial osteolysis model. Collectively, puerarin prevents LPS-induced osteoclast formation, function and bone loss, where the inhibition of Akt activation plays an important role."

According to the news editors, the research concluded: "These findings provide evidences that puerarin might be beneficial as a promising candidate drug for the prevention and treatment of bacteria-induced bone destruction disease, and give new insights for understanding its possible mechanism."

The news correspondents report that additional information may be obtained from Y. Zhang, Shaoxing Univ, Coll Med, Shaoxing 312000, People's Republic of China. Additional authors for this research include M. Yan, Q.F. Yu, P.F. Yang, H.D. Zhang, Y.H. Sun, Z.F. Zhang and Y.F. Gao.

Inflammatory Bowel Diseases and Conditions -

Researchers from Sheba Medical Center Report on Findings in Ulcerative Colitis (Combination of Corticosteroids with 5-Aminosalicylic Acids Compared to Corticosteroids Alone for Hospitalized Patients with Active Ulcerative Colitis)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Inflammatory Bowel Diseases and Conditions - Ulcerative Colitis. According to news originating from Tel Hashomer, Israel, by NewsRx correspondents, research stated, "Although 5-amino-salycilic acids (5-ASA) are often used with corticosteroid treatment in moderate-to severe ulcerative colitis, the value of continuing/initiating 5-ASA in this clinical setting has not been explored. To investigate the impact of a combination 5-ASA+corticosteroid therapy on the outcome of hospitalized patients with acute moderate-severe ulcerative colitis."

Our news journalists obtained a quote from the research from Sheba Medical Center, "We conducted a retrospective study of patients hospitalized with moderate-severe ulcerative colitis in two centers, Israel and South Korea. Patients were classified into those who received 5-ASA and corticosteroids and those who received Corticosteroids alone. Analysis was performed for each hospitalization event. The primary outcome was the rate of treatment failure defined as the need for salvage therapy (cyclosporin-A/infliximab/colectomy). The secondary outcomes were 30 days re-admission rates, in-hospital mortality rates, time to improvement, and
length of hospitalization. We analyzed 209 hospitalization events: 151 patients (72%) received 5-ASA+corticosteroids and 58 (28%) corticosteroids alone. On univariate analysis the combination therapy group had a lower risk for treatment failure (11% vs. 31%, odds ratio 0.28, 95% confidence interval 0.13-0.59, P = 0.001). However, this difference disappeared on multivariate analysis, which showed pre-admission oral corticosteroid treatment to be the most significant factor associated with the need for salvage therapy."

According to the news editors, the research concluded: "A signal for possible benefit of a combination 5-ASA and corticosteroids therapy was found, but was confounded by the impact Of pre-admission corticosteroid treatment."

For more information on this research see: Combination of Corticosteroids with 5-Aminosalicylic Acids Compared to Corticosteroids Alone for Hospitalized Patients with Active Ulcerative Colitis. *Israel Medical Association Journal*, 2016;18(10):613-618. *Israel Medical Association Journal* can be contacted at: Israel Medical Assoc Journal, 2 Twin Towers, 11TH Fl, 35 Jabotinsky St, PO Box 3604, Ramat Gan 52136, Israel.

The news correspondents report that additional information may be obtained from O. Har-Noy, Sheba Med Center Tel Hashomer, Dept. of Gastroenterol, Tel Hashomer, Israel. Additional authors for this research include B. Kim, R. Haiat, T. Engel, B. Ungar, R. Eliakim, W.H. Kim, J.H. Cheon and S. Ben-Horin.

Keywords for this news article include: Tel Hashomer, Israel, Asia, Inflammatory Bowel Diseases and Conditions, Digestive System Diseases and Conditions, Gastrointestinal Diseases and Conditions, Colonic Diseases and Conditions, Clinical Trials and Studies, Post-Trial Research, Ulcerative Colitis, Gastroenterology, Salvage Therapy, Hospitalization, Corticosteroids, Gastroenteritis, Patient Care, Sheba Medical Center.

Our news editors obtained a quote from the research from the Shiraz University of Medical Sciences, "The E2 serum levels in the hCG administration day and third and seventh day after ovum retrieval were measured in control group. The rate of pregnancy was also quantified and compared between the two study groups. There was no significant difference between two study groups regarding baseline characteristics. E2 level decreased significantly in third (1765.34 +/- 680.09; p< 0.001) and seventh (1459.66 +/- 593.80; p< 0.001) days after ovum retrieval (2411.16 +/- 713.52). The authors found that the serum level of E2 was
significantly lower in those who received E2 supplementation at day 3 (p < 0.001) and 7 (p < 0.001). However the pregnancy rate was not significantly different between two study groups (p = 0.849). In the same way, there was no significant difference between two study groups regarding the number of retrieved oocytes (p = 0.563) and number of MII oocytes (p = 0.103). E2 supplementation during the luteal phase in patients with unexplained infertility undergoing IVF, is associated with decreased serum levels of E2 after hCG injection.

According to the news editors, the research concluded: "However the fertility outcome was not affected by E2 supplementation."

The news editors report that additional information may be obtained by contacting S. Shahriver, Shiraz University of Medical Science, Dept. of Obst & Gynecol, Infertil Res Center, Shiraz, Iran. Additional authors for this research include A. Zarei and S. Shahriver.

Drugs and Therapies - Ethnopharmacology

Researchers from Shiraz University of Medical Sciences Report on Findings in Ethnopharmacology (Ethnomedicine for neonatal jaundice: A cross-sectional survey in Qom, Iran)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Drugs and Therapies - Ethnopharmacology are presented in a new report. According to news reporting out of Shiraz, Iran, by NewsRx editors, research stated, "Ethnopharmacological relevance: Traditional Medicine ™ is popularly used for neonatal jaundice in Iran. to provides evidence for characteristics of traditional medicine use in the treatment of neonatal jaundice in Qom, Iran."

Financial support for this research came from Shiraz University of Medical Sciences and Qom University of Medical Sciences.

Our news journalists obtained a quote from the research from the Shiraz University of Medical Sciences, "Field surveys were carried out during July 2015 - August 2015 in Qom through structured questionnaire in Persian from 212 parents of children with neonatal jaundice. All plant species recorded for the treatment of neonatal jaundice were sampled. Samples were identified by a botanist and obtained a voucher specimens number and deposited in the Shiraz School of Pharmacy Herbarium. The information such as scientific name, family, local name, parts used and preparation method were provided. The Use Value (UV), Frequency of Citation (FC), Relative Frequency of Citation (RFC) and Relative Family Importance Value (FIV) are also calculated. In total, 165 (78%) of participants reported the use of traditional methods for
their neonates. The use of herbal remedies was the most popular form of these traditional interventions. A total of 8 plant species belonging to 7 families were identified. Cotoneaster nummularioides Pojark. Cichorium intybus L. Alhagi maurorum Medik. Descurainia sophia (L.) Webb ex Prantl were most frequent herbs used by neonates and their feeding mother to treat jaundice. Manna was the most popular plant part and distillation and soaking were most frequent preparation methods in these patients. The use of TM in these patients is associated with their previous experience on TM use and their view on its potential risk."

According to the news editors, the research concluded: "This study provided information on the prevalence, associated factors and characteristics of traditional medicine use along with ethnomedical knowledge from Qom in Iran on neonatal jaundice."

Our news journalists report that additional information may be obtained by contacting M. Heydari, Shiraz University of Medical Science, Res Center Tradit Med & Hist Med, Shiraz, Iran. Additional authors for this research include H. Heydari, A. Saadati, M. Gharehbeglou, J. Tafaroji and A. Akbari.

**Drugs and Therapies - Cancer Therapy**

**Researchers from Sichuan University Report Details of New Studies and Findings in the Area of Cancer Therapy (Small Molecule TH-39 Potentially Targets Hecl/Nek2 Interaction and Exhibits Antitumor Efficacy in K562 Cells via G0/G1 Cell Cycle ...)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Drugs and Therapies - Cancer Therapy have been published. According to news originating from Chengdu, People's Republic of China, by NewsRx correspondents, research stated, "Cancer is still a major public health issue worldwide, and new therapeutics with anti-tumor activity are still urgently needed. The anti-tumor activity of TH-39, which shows potent anti-proliferative activity against K562 cells with an IC50 of 0.78 mu M, was investigated using immunoblot, co-immunoprecipitation, the MTT assay, and flow cytometry."

Our news journalists obtained a quote from the research from Sichuan University, "Mechanistically, TH-39 may disrupt the interaction between Hecl and Nek2 in K562 cells. Moreover, TH-39 inhibited cell proliferation in a concentration- and time dependent manner by influencing the morphology of K562 cells and inducing G0/G1 phase arrest. G0/G1 phase arrest was associated with down-regulation of CDK2-cyclin E complex and CDK4/6-cyclin D
complex activities. Furthermore, TH-39 also induced cell apoptosis, which was associated with activation of caspase-3, down-regulation of Bcl-2 expression and up regulation of Bax. TH-39 could also decrease mitochondrial membrane potential (Delta psi m) and increase reactive oxygen species (ROS) accumulation in K562 cells. The results indicated that TH-39 might induce apoptosis via the ROS-mitochondrial apoptotic pathway."

According to the news editors, the research concluded: "This study highlights the potential therapeutic efficacy of the anti-cancer compound TH-39 in treatment-resistant chronic myeloid leukemia."

The news correspondents report that additional information may be obtained from N.Y. Wang, Sichuan University, West China Med Sch, West China Hosp, State Key Lab BiotherapyCollaborat Innovat Center B, Chengdu 610041, Sichuan, People's Republic of China. Additional authors for this research include W. Wei, T.H. Ye, Z.H. Liu, L. Liu, Y. Luo, L.D. Zhang, C. Gao, N.Y. Wang and L.T. Yu.

**Acetanilides**

**Researchers from Sichuan University Report Recent Findings in Acetanilides (Effects of Liposomes Charge on Extending Sciatic Nerve Blockade of N-ethyl Bromide of Lidocaine in Rats)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Acetanilides have been published. According to news reporting originating from Chengdu, People's Republic of China, by NewsRx correspondents, research stated, "N-methyl bromide of lidocaine (QX-314) is a potential local anaesthetic with compromised penetration through cell membranes due to its obligated positive charge. Liposomes have been widely used for drug delivery with promising efficacy and safety."

Our news editors obtained a quote from the research from Sichuan University, "Therefore we investigated the local anaesthetic effects and tissue reactions of QX-314 in combination with anionic, cationic or neutral liposomes in rat sciatic nerve block model, and explored the effects of these liposomes on cellular entry of QX-314 in human embryonic kidney 293 cells. The results demonstrated that anionic liposomes substantially prolonged the duration of sensory (25.7 +/- 8.3 h) and motor (41.4 +/- 6.1 h) blocks of QX-314, while cationic and neutral ones had little effects. Tissue reactions from QX-314 with anionic liposomes were similar to those with commonly used local anaesthetic bupivacaine. Consistent with in vivo results, the anionic liposomes produced the greatest promotion of cellular entry of QX-314 in a
time-dependent manner."

According to the news editors, the research concluded: "Ultra-long lasting nerve blocks were achieved by a mixture of QX-314 and anionic liposomes with a satisfactory safety profile, indicating a potential approach to improve postoperative pain management. The liposome-induced enhancement in cellular uptake of QX-314 may underlie the in vivo effects."

The news editors report that additional information may be obtained by contacting W.S. Zhang, Sichuan University, West China Hosp, Dept. of Anaesthesiol, Chengdu 610041, Sichuan, People's Republic of China. Additional authors for this research include B.W. Ke, X.B. Chen, Y.K. Guan, P. Feng, G. Chen, Y. Kang, W.S. Zhang and Y. Nie.

**Oncology - Cancer Prevention**

**Researchers from Sloan Kettering Institute Discuss Findings in Cancer Prevention (The future of clinical cancer genomics)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Oncology - Cancer Prevention have been presented. According to news reporting originating from New York City, New York, by NewsRx editors, the research stated, "The current and future applications of genomics to the practice of preventive oncology are being impacted by a number of challenges."

Our news editors obtained a quote from the research from Sloan Kettering Institute, "These include rapid advances in genomic science and technology that allow massively parallel sequencing of both tumors and the germline, a diminishing of intellectual property restrictions on diagnostic genetic applications, rapid expansion of access to the internet which includes mobile access to both genomic data and tools to communicate and interpret genetic data in a medical context, the expansion of for-profit diagnostic companies seeking to monetize genetic information, and a simultaneous effort to depict medical professionals as barriers to rather than facilitators of understanding one's genome. Addressing each of these issues will be required to bring 'personalized' germline genomics to cancer prevention and care."

According to the news editors, the research concluded: "A profound future challenge will be whether clinical cancer genomics will be 'de-medicalized' by commercial interests and their advocates, or whether the future course of this field can be modulated in a responsible way that protects the public health while implementing powerful new medical tools for cancer prevention and early detection."

For more information on this research see: The future of clinical cancer genomics.
Researchers from Soochow University Discuss Findings in Prostate Cancer (Inhibition of EZH2 by chemo- and radiotherapy agents and small molecule inhibitors induces cell death in castration-resistant prostate cancer)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Oncology - Prostate Cancer. According to news reporting out of Changzhou, People's Republic of China, by NewsRx editors, research stated, "Androgen deprivation therapy is the mainstay of treatment of advanced prostate cancer (PCa). However, a significant portion of patients experience disease relapse and tumors ultimately evolve into castration resistant prostate cancer (CRPC), for which there is no cure in the clinic."

Our news journalists obtained a quote from the research from Soochow University, "The Polycomb protein enhancer of zeste homolog 2 (EZH2) is frequently overexpressed in CRPC. It is unclear whether EZH2 can be a therapeutic target in CRPC. Here, we demonstrated that chemo-and radiotherapy agents such as camptothecin (CPT) and g irradiation decrease EZH2 expression in various PCa cell lines. We provided evidence that functional p53 and RB proteins are required for CPT-and irradiation-induced downregulation of EZH2 in CRPC cells. We further showed that the EZH2 inhibitor GSK126 inhibits both Polycomb-dependent and -independent functions of EZH2 in PCa cells. Importantly, we found that inhibition of EZH2 by genetic and pharmacological means sensitizes CRPC cells to CPT-induced apoptotic death and growth inhibition in culture and in mice."

According to the news editors, the research concluded: "Our data suggest that concomitant administration of small molecule inhibitors of EZH2 may significantly increase the anti-tumor efficacy of conventional chemo-and radiotherapies in CRPC."

For more information on this research see: Inhibition of EZH2 by chemo- and radiotherapy agents and small molecule inhibitors induces cell death in castration-resistant prostate cancer. Oncotarget, 2016;7(3):3440-52.
Researchers from Soonchunhyang University Provide Details of New Studies and Findings in the Area of Aneurysm (Direct Carotid Exposure for Neuroendovascular Approaches)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Cardiovascular Diseases and Conditions - Aneurysm have been presented. According to news reporting originating from Bucheon, South Korea, by NewsRx correspondents, research stated, "The transfemoral approach is a common route for catheterization of the supra-aortic vessels in neuroendovascular therapy. However, in some cases, the patient's anatomy prevents transfemoral catheterization or distal access to the carotid s. In such cases, direct carotid exposure (DCE) for neuroendovascular approaches may be used to treat cerebrovascular diseases."

Our news editors obtained a quote from the research from Soonchunhyang University, "We present 11 cases in which we were unable to perform the distal approach and DCE was the preferred neuroendovascular treatment procedure. DCE was performed on 11 patients with cerebral aneurysm (n = 8), carotid cavernous fistula (CCF) (n = 1), malignant brain tumor (n = 1), and carotid angioplasty and stenting (n = 1). Ten patients were female; one was male. Ages ranged from 63 to 87 years (mean: 71.36 years). Coil embolization was performed on patients with cerebral aneurysm and CCF. The patient with a malignant brain tumor underwent polyvinyl alcohol particle embolization. The only complication was a carotid artery dissection that occurred in one patient during stenting. DCE for neuroendovascular approaches can be used as an alternative for patients with tortuous vasculature access in the femoral route."

According to the news editors, the research concluded: "In such patients, a combination of neuroendovascular treatment and surgery in a hybrid operating room with angiography is preferred."

The news editors report that additional information may be obtained by contacting
Researchers from Sorbonne University Report Recent Findings in Antiretrovirals (Influence of geographic origin, sex, and HIV transmission group on the outcome of first-line combined antiretroviral therapy in France)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Drugs and Therapies - Antiretrovirals are presented in a new report. According to news originating from Paris, France, by NewsRx correspondents, research stated, "More data are needed on the influence of geographic origin, sex, and the HIV transmission group on biological and clinical outcomes after first-line combined antiretroviral therapy (cART) initiation. We studied antiretroviral-naive HIV-1-infected adults enrolled in the French Hospital Database on HIV cohort in France and who started cART between 2006 and 2011."

Our news journalists obtained a quote from the research from Sorbonne University, "The censoring date of the study was 31 December 2012. According to geographic origin [French natives (FRA) or sub-Saharan Africa/non-French West Indies (SSA/NFW)], sex, and HIV transmission group, we assessed 2-year Kaplan-Meier probabilities and adjusted hazard ratios (aHRs) for plasma viral load undetectability and CD4(+) cell recovery, and 5-year cumulative incidences and aHRs for negative clinical outcomes (AIDS-defining event, serious non-AIDS events, or death). Of 9746 eligible individuals, 7297 (74.9%) were FRA and 2449 (25.1%) were sub-Saharan Africa/non-French West Indies migrants. More migrants (38.1%) than nonmigrants (27.5%) started cART with a CD4(+) cell count less than 200/ml (P < 0.0001). By comparison with FRA MSM, nonhomosexual men, whatever their geographic origin, had lower aHRs for viral undetectability; all patient groups, particularly migrants, had lower aHRs for CD4(+) cell recovery than FRA MSM; aHRs for negative clinical outcome (360 new AIDS-defining events, 1376 serious non-AIDS events, 38 deaths) were also higher in nonhomosexual men, regardless of geographic origin. Preexisting AIDS status, a lower CD4(+) cell count and older age at cART initiation had the biggest impact on changes between the crude and aHRs of clinical outcomes."

According to the news editors, the research concluded: "Compared with FRA MSM, all migrants had a lower likelihood of CD4(+) cell recovery, and nonhomosexual men had a higher likelihood of negative virological and clinical outcomes."

For more information on this research see: Influence of geographic origin, sex, and HIV transmission group on the outcome of first-line combined antiretroviral therapy in France. Aids, 2016;30(14):2235-2246. Aids can be contacted at: Lippincott Williams & Wilkins, Two Commerce Sq, 2001 Market St, Philadelphia, PA 19103, USA. (Lippincott Williams and
Researchers from Southern Medical University Describe Findings in Non-Small Cell Lung Cancer (Randomized Adjuvant Chemotherapy of EGFR-Mutated Non-Small Cell Lung Cancer Patients with or without Icotinib Consolidation Therapy)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Oncology - Non-Small Cell Lung Cancer is now available. According to news reporting originating from Guangdong, People's Republic of China, by NewsRx correspondents, research stated, "Epidermal growth factor receptor (EGFR) mutations occur in up to 50% of Asian patients with non-small cell lung cancer (NSCLC). Treatment of advanced NSCLC patients with EGFR-tyrosine kinase inhibitor (EGFR-TKI) confers a significant survival benefit."

Our news editors obtained a quote from the research from Southern Medical University, "This study assessed the efficacy and safety of chemotherapy with or without icotinib in patients undergoing resection of stage IB to IIIA EGFR-mutated NSCLC. Patients with surgically resected stage IB (with high risk factors) to IIIA EGFR-mutated NSCLC were randomly assigned (1:1) to one of two treatment plans. One group received four cycles of platinum-based doublet chemotherapy every three weeks, and the other group received platinum-based chemotherapy supplemented with consolidation therapy of orally administered icotinib (125 mg thrice daily) two weeks after chemotherapy. The icotinib treatment continued for four to eight months, or until the occurrence of disease relapse, metastasis or unacceptable icotinib or chemotherapy toxicity. The primary endpoint was disease-free survival (DFS). 41 patients were enrolled between Feb 9, 2011 and Dec 17, 2012. 21 patients were assigned to the combined chemotherapy plus icotinib treatment group, while 20 patients received chemotherapy only. DFS at 12 months was 100% for icotinib-treated patients and 88.9% for chemotherapy-only patients (p=0.122). At 18 months DFS for icotinib-treated vs. chemotherapy-only patients was 95.2% vs. 83.3% (p=0.225), respectively, and at 24 months DFS was 90.5% vs. 66.7% (p=0.066). The adverse chemotherapy effects predominately presented as gastrointestinal reactions and marrow suppression, and there was no significant difference between the two treatment groups. Patients in the chemotherapy plus icotinib treatment group showed favorable tolerance to oral icotinib. The results suggest that chemotherapy plus orally icotinib displayed better DFS compared with chemotherapy only, yet the difference in DFS was not significant."
According to the news editors, the research concluded: "We would think the preliminary result here was promising, and further trials with larger sample sizes might confirm the efficiency of adjuvant TKI in selected patients."

For more information on this research see: Randomized Adjuvant Chemotherapy of EGFR-Mutated Non-Small Cell Lung Cancer Patients with or without Icotinib Consolidation Therapy. *Plos One*, 2015;10(10):e0140794. (Public Library of Science - www.plos.org; Plos One - www.plosone.org)

**Oncology - Breast Cancer**

**Researchers from Southern Medical University Provide Details of New Studies and Findings in the Area of Breast Cancer (Doublecortin-like kinase 1 expression associates with breast cancer with neuroendocrine differentiation)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Oncology - Breast Cancer is the subject of a report. According to news reporting out of Shenzhen, People's Republic of China, by NewsRx editors, research stated, "Doublecortin-like kinase 1 (DCLK1), a microtubule associated kinase, has recently been proposed to be a putative marker for stemness and adverse prognosis in gastrointestinal cancers. However, it is not clear whether the protein also plays similar roles in breast cancer."

Our news journalists obtained a quote from the research from Southern Medical University, "Here, the expression of DCLK1 was analyzed in a large cohort of invasive breast cancers (IBC) by immunohistochemistry. DCLK1 was associated with favorable clinicopathologic features, namely lower histologic grade, absence of lymphovascular invasion, fibrotic focus, necrosis and lower pN stage (p (<=)0.045). Additionally, independent significant correlations were found with estrogen receptor and neuroendocrine markers (p (<=)0.019), implicating its relationship with IBC with neuroendocrine differentiation (IBC-NED). In the current cohort, IBC-NED showed worse outcome than luminal cancers without NED (hazard ratio=1.756, p=0.041). Interestingly, within the IBC-NED group, DCLK1 was found to be a good prognostic factor (hazard ratio=0.288, p=0.011). These findings were in contrast to those in gastrointestinal cancers, suggesting different functional roles of DCLK1 in different types of..."
cancers. In clinical practice, NED is not routinely assessed; thus IBC-NED are not well studied. Its poor outcome and significant heterogeneity warrants more attention.

According to the news editors, the research concluded: "DCLK1 expression could aid in the prognostication and management of this special cancer subtype."

For more information on this research see: Doublecortin-like kinase 1 expression associates with breast cancer with neuroendocrine differentiation. Oncotarget, 2016;7(2):1464-76.

Our news journalists report that additional information may be obtained by contacting Y.H. Liu, Dept. of Pathology, The Affiliated Baoan Hospital of Southern Medical University, Shenzhen, People's Republic of China. Additional authors for this research include J.Y. Tsang, Y.B. Ni, T. Hlaing, S.K. Chan, K.F. Chan, C.W. Ko, S.S. Mujtaba and G.M Tse.

Oncology - Pancreatic Cancer

Researchers from Southern Medical University Report Details of New Studies and Findings in the Area of Pancreatic Cancer (Twist promotes angiogenesis in pancreatic cancer by targeting miR-497/VEGFA axis)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Oncology - Pancreatic Cancer is the subject of a report. According to news originating from Guangdong, People's Republic of China, by NewsRx correspondents, research stated, "Angiogenesis is a critical step in the growth and dissemination of malignant diseases, including pancreatic cancer. Twist has been shown to stimulate angiogenesis in the tumor site."

Our news journalists obtained a quote from the research from Southern Medical University, "However, whether Twist contributes to angiogenesis in pancreatic cancer remains unknown. In this paper, we found that the expression of Twist was significantly increased in human pancreatic cancer cell lines and pancreatic cancer specimens. It is also closely engaged to adverse clinical feature, diminished survival and angiogenesis in pancreatic cancer patients. The up-regulation of Twist was found to be promoting cell growth, invasion and tubule formation of human umbilical vein endothelial cells (HUVECs) in vitro. By contrast, the silencing of Twist inhibited orthotopic xenograft tumor growth, metastasis and angiogenesis. Subsequent investigations disclosed that Twist was regulated by miR-497 directly, leading to the increased level of Vascular Endothelial Growth Factor-A (VEGFA). Moreover, gain-of-function and loss-of-function studies demonstrated that miR-497 could suppress the pro-proliferative, angiogenic and metastatic ability of pancreatic cancer cells. The ectopic expression of VEGFA obviously abrogated the anti-angiogenic effect induced by Twist knockdown, whereas the silencing of VEGFA markedly rescued the pro-angiogenic effect of Twist. By analyzing the expression levels of miR-497, Twist was found inversely correlated with miR-497 in pancreatic cancer..."
tissues, and a positive correlation was found between Twist and VEGFA levels in pancreatic cancer specimens."

According to the news editors, the research concluded: "Our results suggested that the Twist/miR-497/VEGFA axis is significantly correlated with metastasis and angiogenesis in pancreatic cancer."

For more information on this research see: Twist promotes angiogenesis in pancreatic cancer by targeting miR-497/VEGFA axis. Oncotarget, 2016;7(18):25801-14.

The news correspondents report that additional information may be obtained from A. Researchers from Southern Medical University Report New Studies and Findings in the Area of Liver Cancer (Hyperthermia enhances 17-DMAG efficacy in hepatocellular carcinoma cells with aggravated DNA damage and impaired G2/M transition)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Oncology - Liver Cancer have been published. According to news reporting from Guangdong, People’s Republic of China, by NewsRx journalists, research stated, "Due to the lack of effective treatment, hepatocellular carcinoma (HCC) is one of the malignancies with low survival rates worldwide. Combination of hyperthermia and chemotherapy has shown promising results in several abdominal tumours, but high expression of HSP90 in tumours attenuated the efficacy of hyperthermia."

The news correspondents obtained a quote from the research from Southern Medical University, "Thus a combination of hyperthermia and inhibition of HSP90 might be a feasible therapeutic strategy for HCC. One hepatic cell line (L02) and two HCC cell lines (Huh7 and HepG2) were heated at 42 degrees C for 0, 0.5 or 4 h with or without 100 nM 17-dimethylaminoethylamino17-demethoxygeldanamycin (17-DMAG). HCC cells of the combination group exhibited more G2/M arrest and higher apoptotic rates which might result from suffering from more reactive oxygen species and serious DNA damage. Heat shock/17-DMAG co-treatment of HCC cells also destabilized CDK1, Cyclin B1 and CDC25C with a concomitant decreased proportion of cells in the M phase. Furthermore, co-treatment impaired the interaction of HSP90 alpha with CDC37 and with CDK1, accompanied with decreased soluble CDK1. Combination of 17-DMAG with a 1.5-h whole body hyperthermia treatment attenuated tumour growth in xenograft mice models."

According to the news reporters, the research concluded: "These results suggest hyperthermia sensitize HCC to 17-DMAG, and combination of hyperthermia with 17-DMAG
might be a potential therapeutic strategy for HCC."

For more information on this research see: Hyperthermia enhances 17-DMAG efficacy in hepatocellular carcinoma cells with aggravated DNA damage and impaired G2/M transition. Scientific Reports, 2016;6():1-11. Scientific Reports can be contacted at: Nature Publishing Group, Macmillan Building, 4 Crinan St, London N1 9XW, England. **Fluids Research**

**Researchers from Southwest Jiaotong University Provide Details of New Studies and Findings in the Area of Fluids Research (Geometry design of herringbone structures for cancer cell capture in a microfluidic device)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Fluids Research. According to news reporting out of Chengdu, People's Republic of China, by NewsRx editors, research stated, "Cancer cell detection with high capture efficiency is important for its extensive clinical applications. Herringbone structures in microfluidic devices have been widely adopted to increase the cell capture performance due to its chaotic effect."

Our news journalists obtained a quote from the research from Southwest Jiaotong University, "Given the fact of laminar flow in microfluidic devices, geometry-based optimization acting as a design strategy is effective and can help researchers reduce repetitive trial experiments. In this work, we presented a computational model to track the cell motion and used normalized capture efficiency to evaluate the tumor cell capture performance under various geometry settings. Cell adhesion probability was implemented in the model to consider the nature of ligand-receptor formation and breakage during cell-surface interactions. A facile approach was introduced to determine the two lumped coefficients of cell adhesion probability through two microfluidic experiments. A comprehensive geometric study was then performed by using this model, and results were explained from the fluid dynamics. Although most of the geometric guides agree with the general criterion concluded in the literature, we found herringbone structures with symmetric arms rather than a short arm-long arm ratio of 1/3 are optimal. This difference mainly comes from the fact that our model considers the particulate nature of cells while most studies in the literature optimize the geometry merely relying on mixing effects."

According to the news editors, the research concluded: "Thus, our computational model implemented with cell adhesion probability can serve as a more accurate and reliable approach to optimize microfluidic devices for cancer cell capture."
For more information on this research see: Geometry design of herringbone structures for cancer cell capture in a microfluidic device. *Microfluidics and Nanofluidics*, 2016;20(11):16-26. *Microfluidics and Nanofluidics* can be contacted at: Springer Heidelberg, Tiergartenstrasse 17, D-69121 Heidelberg, Germany. **Drugs and Therapies - Controlled Release Research**

**Researchers from Southwest Jiaotong University Report New Studies and Findings in the Area of Controlled Release Research (Shape effects of electrospun fiber rods on the tissue distribution and antitumor efficacy)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Drugs and Therapies - Controlled Release Research. According to news originating from Chengdu, People's Republic of China, by NewsRx correspondents, research stated, "The significant impact of drug-loaded nanocarriers on cancer chemotherapy lies in the ability to specifically target to tumors with alleviated systemic toxicities. In the current study, a versatile and scalable method has been developed to construct fiber rods from electrospun fibers by ultrasonication using encapsulated NaCl nanoparticles as void-precursors."

Financial supporters for this research include National Natural Science Foundation of China, Specialized Research Fund, Fundamental Research Funds.

Our news journalists obtained a quote from the research from Southwest Jiaotong University, "The shape effects of doxorubicin (DOX)-loaded fiber rods with an average diameter of around 500 nm and different lengths are determined on the blood circulation, tumor accumulation and cellular uptake. Compared with microspheres, fiber rods indicate an up to 4-fold higher accumulation in tumors and an up to 3-fold longer terminal half-life of plasma DOX levels after intravenous injection. Fiber rods with shorter lengths show a significantly higher in vitro cytotoxicity to tumor cells, a higher DOX accumulation and cell necrosis in tumors, and a significantly lower metastasis in lungs. Among fiber rods with different lengths, fiber rods with an average length of 2 μm induce significantly higher inhibition on tumor cell proliferation and induction of cell apoptosis, as well as no detectable metastatic nodules in lung sections."

According to the news editors, the research concluded: "Therefore, the shape effects of electrospun fiber rods hold great potential for enhancing systemic circulation and directing biodistribution to improve therapeutic outcomes."

For more information on this research see: Shape effects of electrospun fiber rods on the tissue distribution and antitumor efficacy. *Journal of Controlled Release*, 2016;244():52-62. *Journal of Controlled Release* can be contacted at: Elsevier Science Bv, PO Box 211, 1000 Ae
Researchers from Spanish National Research Council (CSIC) Detail New Studies and Findings in the Area of Retinal and Eye Research (Autophagy in the eye: Development, degeneration, and aging)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Health and Medicine - Retinal and Eye Research are discussed in a new report. According to news reporting out of Madrid, Spain, by NewsRx editors, research stated, "Autophagy is a catabolic pathway that promotes the degradation and recycling of cellular components. Proteins, lipids, and even whole organelles are engulfed in autophagosomes and delivered to the lysosome for elimination."

Financial support for this research came from CSIC.

Our news journalists obtained a quote from the research from Spanish National Research Council (CSIC), "In response to stress, autophagy mediates the degradation of cell components, which are recycled to generate the nutrients and building blocks required to sustain cellular homeostasis. Moreover, it plays an important role in cellular quality control, particularly in neurons, in which the total burden of altered proteins and damaged organelles cannot be reduced by redistribution to daughter cells through cell division. Research has only begun to examine the role of autophagy in the visual system. The retina, a light-sensitive tissue, detects and transmits electrical impulses through the optic nerve to the visual cortex in the brain. Both the retina and the eye are exposed to a variety of environmental insults and stressors, including genetic mutations and age-associated alterations that impair their function. 3-lere, we review the main studies that have sought to explain autophagy's importance in visual function. We describe the role of autophagy in retinal development and cell differentiation, and discuss the implications of autophagy dysregulation both in physiological aging and in important diseases such as age associated macular degeneration and glaucoma. We also address the putative role of autophagy in promoting photoreceptor survival and discuss how selective autophagy could provide alternative means of protecting retinal cells."

According to the news editors, the research concluded: "The findings reviewed here underscore the important role of autophagy in maintaining proper retinal function and highlight novel therapeutic approaches for blindness and other diseases of the eye."

For more information on this research see: Autophagy in the eye: Development,

Our news journalists report that additional information may be obtained by contacting P. Boya, CSIC, Center Invest Biol, Dept. of Cellular & Mol Biol, Autophagy Lab, Madrid 28040, Spain. **Drugs and Therapies - Pharmacology**

**Researchers from St. George's University of London Provide Details of New Studies and Findings in the Area of Pharmacology (The calcilytics Calhex-231 and NPS 2143 and the calcimimetic Calindol reduce vascular reactivity via inhibition of ...)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Drugs and Therapies - Pharmacology. According to news reporting from London, United Kingdom, by NewsRx journalists, research stated, "The present study investigates the effect of commonly used negative and positive allosteric modulators of the calcium-sensing receptor (CaSR) on vascular reactivity. In wire myography studies, increasing [Ca2+](o) from 1 mM to 6 mM induced concentration-dependent relaxations of methoxamine-induced pre-contracted rabbit mesenteric arteries, with 6 mM [Ca2+](o) producing almost complete relaxation."

Funders for this research include British Heart Foundation, UK, Biotechnology and Biological Sciences Research Council.

The news correspondents obtained a quote from the research from the St. George's University of London, "[Ca2+](o)-induced relaxations were attenuated in the presence of the calcilytics Calhex-231 and NPS 2143, and abolished by the removal of the endothelium. In addition to their calcilytic effects, Calhex-231 and NPS 2143 also produced concentration-dependent inhibitions of methoxamine-or KCl-induced precontracted tone, which were unaffected by removal of the endothelium and unopposed in the presence of the calcimimetic Calindol. In vessels with depleted Ca2+ stores, contractions mediated by Ca2+ influx via voltage-gated Ca2+ channels (VGCCs) were inhibited by Calhex231. In freshly isolated single rabbit mesenteric artery smooth muscle cells, Calhex-231 and NPS 2143 inhibited whole-cell VGCC currents. Application of Calindol also inhibited methoxamine-and KCl-induced precontracted tone, and inhibited whole-cell VGCC currents."

According to the news reporters, the research concluded: "In addition to their CaSR-mediated actions in the vasculature, Calhex-231, NPS 2143 and Calindol reduce vascular
contractility via direct inhibition of VGCCs."

For more information on this research see: The calcilytics Calhex-231 and NPS 2143 and the calcimimetic Calindol reduce vascular reactivity via inhibition of voltage-gated Ca2+ channels. European Journal of Pharmacology, 2016;791():659-668. European Journal of Pharmacology can be contacted at: Elsevier Science Bv, PO Box 211, 1000 Ae Amsterdam, Netherlands. (Elsevier - www.elsevier.com; European Journal of Pharmacology - www.journals.elsevier.com/european-journal-of-pharmacology/)

Peptides and Proteins

Researchers from St. James University Report Findings in Peptides and Proteins (Immunogenicity of self tumor associated proteins is enhanced through protein truncation)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Peptides and Proteins have been presented. According to news reporting out of Leeds, United Kingdom, by NewsRx editors, research stated, "We showed previously that therapy with Vesicular Stomatitis Virus (VSV) expressing tumor-associated proteins eradicates established tumors. We show here that when cellular cDNA were cloned into VSV which retained their own poly-A signal, viral species emerged in culture which had deleted the cellular poly- A signal and also contained a truncated form of the protein coding sequence."

Our news journalists obtained a quote from the research from St. James University, "Typically, the truncation occurred such that a Tyrosine-encoding codon was converted into a STOP codon. We believe that the truncation of tumor-associated proteins expressed from VSV in this way occurred to preserve the ability of the virus to replicate efficiently. Truncated cDNA expressed from VSV were significantly more effective than full length cDNA in treating established tumors. Moreover, tumor therapy with truncated cDNA was completely abolished by depletion of CD4+ T cells, whereas therapy with full length cDNA was CD8+ T cell dependent. These data show that the type/potency of antitumor immune responses against self-tumor-associated proteins can be manipulated in vivo through the nature of the self protein (full length or truncated)."

According to the news editors, the research concluded: "Therefore, in addition to generation of neoantigens through sequence mutation, immunological tolerance against self-tumor-associated proteins can be broken through manipulation of protein integrity, allowing for rational design of better self-immunogens for cancer immunotherapy."

For more information on this research see: Immunogenicity of self tumor associated proteins is enhanced through protein truncation.

**Heart Disorders and Diseases – Atrial Fibrillation**

**Researchers from St. Louis University Detail Findings in Atrial Fibrillation (A randomized, prospective pilot comparison of 3 atrial appendage elimination techniques: Internal ligation, stapled excision, and surgical excision)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Heart Disorders and Diseases - Atrial Fibrillation. According to news reporting from St. Louis, Missouri, by NewsRx journalists, research stated, "Elimination of the left atrial appendage (LAA) attempts to reduce stroke in patients with atrial fibrillation (AF). A retrospective review suggests that various surgical techniques are often unsuccessful and may leave a stump or gap."

The news correspondents obtained a quote from the research from St. Louis University, "In a pilot study, we prospectively evaluated 3 surgical techniques with long-term follow up to define effectiveness. At a single institution, 28 patients undergoing concomitant AF surgery were randomized prospectively into 1 of 3 techniques of LAA elimination: internal suture ligation (IL), external stapled excision (StEx), and surgical excision (SxEx). The success of LAA elimination was assessed by transesophageal echocardiography (TEE) in all patients at the time of surgery. Failure of LAA closure consisted of either a stump (residual appendage tissue > 1 cm in maximum length) or a gap (persistent flow between the left atrium [LA] and the LAA). Failure was treated intraoperatively when recognized. Late follow-up was obtained using a TEE at a mean of 0.4 years in 21/28 (75%) of patients. Early failure was recognized and treated in 1 patient in the IL group (13%), 6 patients in the StEx group (60%), and 2 patients in the SxEx group (20%) (P = .06). On follow-up TEE, 4 of 7 patients in the IL group (57%) had developed gaps, 3 of whom (43%) with greater than mild flow. No patients in the StEx or SxEx groups had a gap (P = .03). In late follow-up, 1 of 7 patients in the IL group (14%) had a stump, compared with 2 of 8 (25%) in the StEx group and 3 of 6 (50%) in the SxEx group (P = .35). The overall failure rate was 57%: 5 of 8 (63%) in the IL group, 6 of 10 (60%) in the StEx group, and 5 of 10 (50%) in the SxEx group (P = .85). No patient had a stroke at any time during follow-up. LAA elimination is often incomplete and goes undetected. If the LAA is eliminated at the time of surgery, then TEE should be used intraoperatively to assess effectiveness and reintervention performed if warranted."

According to the news reporters, the research concluded: "Late assessment for
completeness of closure should be considered before cessation of anticoagulation until more effective LAA techniques can be developed."

Our news journalists report that additional information may be obtained by contacting R. Lee, St. Louis University, Center Comprehens Cardiovasc Care, St Louis, MO 63110, United States. **Oncology - Gastric Cancer**

**Researchers from Stanford University Describe Findings in Gastric Cancer (Genetic predisposition to gastric cancer)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Oncology - Gastric Cancer are presented in a new report. According to news reporting out of Stanford, California, by NewsRx editors, research stated, "Gastric cancer ranks as the third leading cause of cancer mortality worldwide and confers a 5-year survival of 20%. While most gastric cancers are sporadic, similar to 1%-3% can be attributed to inherited cancer predisposition syndromes."

Our news journalists obtained a quote from the research from Stanford University, "Germline E-cadherin/CDH1 mutations have been identified in families with an autosomal dominant inherited predisposition to diffuse gastric cancer. The cumulative risk of gastric cancer for CDH1 mutation carriers by age 80 years is reportedly 70% for men and 56% for women. Female mutation carriers also have an estimated 42% risk for developing lobular breast cancer by age 80 years. However, most individuals meeting clinical criteria for hereditary diffuse gastric cancer syndrome (HDGC) do not have a germline CDH1 mutation, and germline CDH1 mutation carriers do not all exhibit similar clinical outcomes in terms of age of diagnosis or cancer types. E-cadherin (CDH1) as the one known causative gene for HDGC accounts for only 40% of cases, leaving 60% with an unknown genetic diagnosis."

According to the news editors, the research concluded: "In addition to HDGC, we will review other genetic syndromes with elevated gastric cancer risk, as well as newly implicated alterations in other genes (CTNNA1, DOT1L, FBX024, PRSS1, MAP3K6, MSR1, and INSR) that may affect gastric cancer susceptibility and age-specific penetrance."
Researchers from Stanford University Detail New Studies and Findings in the Area of Ebola Virus (Diagnosis of Ebola Virus Disease: Past, Present, and Future)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Ebola Virus. According to news reporting originating from Palo Alto, California, by NewsRx correspondents, research stated, "Laboratory diagnosis of Ebola virus disease plays a critical role in outbreak response efforts; however, establishing safe and expeditious testing strategies for this high-biosafety-level pathogen in resource-poor environments remains extremely challenging. Since the discovery of Ebola virus in 1976 via traditional viral culture techniques and electron microscopy, diagnostic methodologies have trended toward faster, more accurate molecular assays."

Our news editors obtained a quote from the research from Stanford University, "Importantly, technological advances have been paired with increasing efforts to support decentralized diagnostic testing capacity that can be deployed at or near the point of patient care. The unprecedented scope of the 2014-2015 West Africa Ebola epidemic spurred tremendous innovation in this arena, and a variety of new diagnostic platforms that have the potential both to immediately improve ongoing surveillance efforts in West Africa and to transform future outbreak responses have reached the field. In this review, we describe the evolution of Ebola virus disease diagnostic testing and efforts to deploy field diagnostic laboratories in prior outbreaks."

According to the news editors, the research concluded: "We then explore the diagnostic challenges pervading the 2014-2015 epidemic and provide a comprehensive examination of novel diagnostic tests that are likely to address some of these challenges moving forward."

For more information on this research see: Diagnosis of Ebola Virus Disease: Past, Present, and Future. *Clinical Microbiology Reviews*, 2016;29(4):773-793. *Clinical Microbiology Reviews* can be contacted at: Amer Soc Microbiology, 1752 N St NW,
Researchers from Stanford University Discuss Findings in Biologics (Emerging Strategies for Developing Next-Generation Protein Therapeutics for Cancer Treatment)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Biotechnology - Biologics is the subject of a report. According to news originating from Stanford, California, by NewsRx correspondents, research stated, "Protein-based therapeutics have been revolutionizing the oncology space since they first appeared in the clinic two decades ago."

Our news journalists obtained a quote from the research from Stanford University, "Unlike traditional small molecule chemotherapeutics, protein biologics promote active targeting of cancer cells by binding to cell-surface receptors and other markers specifically associated with or overexpressed on tumors versus healthy tissue. While the first approved cancer biologics were monoclonal antibodies, the burgeoning field of protein engineering is spawning research on an expanded range of protein formats and modifications that allow tuning of properties such as target binding affinity, serum half-life, stability, and immunogenicity."

According to the news editors, the research concluded: "In this review we highlight some of these strategies and provide examples of modified and engineered proteins under development as preclinical and clinical-stage drug candidates for the treatment of cancer."

The news correspondents report that additional information may be obtained from J.R. Cochrane, Stanford University, Dept. of Chem Engn, Stanford, CA 94305, United States. Additional authors for this research include M.V.F. Interrante and J.R. Cochrane.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1016/j.tips.2016.10.005. This DOI is a link to an online electronic document.
Researchers from Stanford University Discuss Findings in Drug Delivery Systems (Engineered knottin peptides as diagnostics, therapeutics, and drug delivery vehicles)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Drugs and Therapies - Drug Delivery Systems have been presented. According to news reporting out of Stanford, California, by NewsRx editors, research stated, "Inhibitor cystine-knots, also known as knottins, are a structural family of ultra-stable peptides with diverse functions. Knottins and related backbone-cyclized peptides called cyclotides contain three disulfide bonds connected in a particular arrangement that endows these peptides with high thermal, proteolytic, and chemical stability."

Financial support for this research came from NSF Graduate Research Fellowship.

Our news journalists obtained a quote from the research from Stanford University, "Knottins have gained interest as candidates for non-invasive molecular imaging and for drug development as they can possess the pharmacological properties of small molecules and the target affinity and selectively of protein biologics. Naturally occurring knottins are clinically approved for treating chronic pain and GI disorders. Combinatorial methods are being used to engineer knottins that can bind to other clinically relevant targets in cancer, and inflammatory and cardiac disease."

According to the news editors, the research concluded: "This review details recent examples of engineered knottin peptides; their use as molecular imaging agents, therapeutics, and drug delivery vehicles; modifications that can be introduced to improve peptide folding and bioactivity; and future perspectives and challenges in the field."

Our news journalists report that additional information may be obtained by contacting J.R. Cochran, Stanford University, Dept. of Chem Engn, Stanford, CA 94305, United States.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1016/j.cbpa.2016.08.022. This DOI is a link to an online electronic document that is either free or for purchase.

Researchers from Stanford University Discuss Findings in Lymphoid Leukemia (E2A-PBX1 Remodels Oncogenic Signaling Networks in B-cell Precursor Acute Lymphoid Leukemia)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Oncology - Lymphoid Leukemia are presented in a new report. According to news reporting originating from Stanford, California, by NewsRx correspondents, research stated, "There is limited understanding of how signaling pathways are altered by oncogenic fusion transcription factors that drive leukemogenesis. To address this, we interrogated activated signaling pathways in a comparative analysis of mouse and human leukemias expressing the fusion protein E2A-PBX1, which is present in 5%-7% of pediatric and 50% of pre-B-cell receptor (preBCR(+)) acute lymphocytic leukemia (ALL)."

Our news editors obtained a quote from the research from Stanford University, "In this study, we describe remodeling of signaling networks by E2APBX1 in pre-B-ALL, which results in hyperactivation of the key oncogenic effector enzyme PLC gamma 2. Depletion of PLC gamma 2 reduced proliferation of mouse and human ALLs, including E2A-PBX1 leukemias, and increased disease-free survival after secondary transplantation. Mechanistically, E2A-PBX1 bound promoter regulatory regions and activated the transcription of its key target genes ZAP70, SYK, and LCK, which encode kinases upstream of PLC gamma 2. Depletion of the respective upstream kinases decreased cell proliferation and phosphorylated levels of PLC gamma 2 (pPLC gamma 2). Pairwise silencing of ZAP70, SYK, or LCK showed additive effects on cell growth inhibition, providing a rationale for combination therapy with inhibitors of these kinases. Accordingly, inhibitors such as the SRC family kinase (SFK) inhibitor dasatinib reduced pPLC gamma 2 and inhibited proliferation of human and mouse preBCR(+)/E2A-PBX1 (+) leukemias in vitro and in vivo. Furthermore, combining small-molecule inhibition of SYK, LCK, and SFK showed synergistic interactions and preclinical efficacy in the same setting."

According to the news editors, the research concluded: "Our results show how the oncogenic fusion protein E2A-PBX1 perturbs signaling pathways upstream of PLC gamma 2 and renders leukemias amenable to targeted therapeutic inhibition."

For more information on this research see: E2A-PBX1 Remodels Oncogenic Signaling Networks in B-cell Precursor Acute Lymphoid Leukemia. Cancer Research, 2016;76 (23):6937-6949. Machado-Joseph Disease

Researchers from State University of Campinas Provide Details of New Studies and Findings in the Area of Machado-Joseph Disease (Lithium carbonate and coenzyme Q10 reduce cell death in a cell model of Machado-Joseph disease)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Machado-Joseph disease is now available. According to news originating from Campinas, Brazil, by NewsRx correspondents, research stated, "Machado-Joseph disease (MJD) or spinocerebellar ataxia type 3 (SCA3) is an autosomal dominant neurodegenerative disorder caused by expansion of the polyglutamine domain of the ataxin-3 (ATX3) protein. MJD/SCA3 is the most frequent autosomal dominant ataxia in many countries."

Our news journalists obtained a quote from the research from the State University of Campinas, "The mechanism underlying MJD/SCA3 is thought to be mainly related to protein misfolding and aggregation leading to neuronal dysfunction followed by cell death. Currently, there are no effective treatments for patients with MJD/SCA3. Here, we report on the potential use of lithium carbonate and coenzyme Q10 to reduce cell death caused by the expanded ATX3 in cell culture. Cell viability and apoptosis were evaluated by MTT assay and by flow cytometry after staining with annexin V-FITC/propidium iodide. Treatment with lithium carbonate and coenzyme Q10 led to a significant increase in viability of cells expressing expanded ATX3 (Q84). In addition, we found that the increase in cell viability resulted from a significant reduction in the proportion of apoptotic cells. Furthermore, there was a significant change in the expanded ATX3 monomeraggregate ratio after lithium carbonate and coenzyme Q10 treatment, with an increase in the monomer fraction and decrease in aggregates."

According to the news editors, the research concluded: "The safety and tolerance of both drugs are well established; thus, our results indicate that lithium carbonate and coenzyme Q10 are good candidates for further in vivo therapeutic trials."

For more information on this research see: Lithium carbonate and coenzyme Q10 reduce cell death in a cell model of Machado-Joseph disease. Brazilian Journal of Medical and Biological Research, 2016;49(12):19-25. Brazilian Journal of Medical and Biological Research can be contacted at: Assoc Bras Divulg Cientifica, Faculdade Medicina, Sala 21, 14049 Ribeirao Preto, Sao Paulo, 00, Brazil.

The news correspondents report that additional information may be obtained from I. Lopes-Cendes, Campinas State University, Fac Ciencias Med, Dept. of Med Genet, Campinas, SP, Brazil. Additional authors for this research include T.C. Pereira, D.B. Dogini, R. Gilioli and I. Lopes-Cendes.

Gram-Positive Bacteria - Streptococcus

Researchers from State University of Campinas Report Recent Findings in Streptococcus (CovR Regulates Streptococcus mutans Susceptibility To Complement Immunity and Survival in Blood)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Gram-Positive Bacteria - Streptococcus. According to news reporting originating in Piracicaba, Brazil, by NewsRx journalists, research stated, "Streptococcus mutans, a major pathogen of dental caries, may promote systemic infections after accessing the bloodstream from oral niches. In this study, we investigate pathways of complement immunity against S. mutans and show that the orphan regulator CovR (CovR(Sm)) modulates susceptibility to complement opsonization and survival in blood. S. mutans blood isolates showed reduced susceptibility to C3b deposition compared to oral isolates."

Funders for this research include Japan Society for the Promotion of Science (JSPS), Coordenacao de Aperfeicoamento de Pessoal de Nivel Superior (CAPES), Fundacao de Amparo a Pesquisa do Estado de Sao Paulo (FAPESP).

The news reporters obtained a quote from the research from the State University of Campinas, "Reduced expression of covRSm in blood strains was associated with increased transcription of CovR(Sm)-repressed genes required for S. mutans interactions with glucans (gbpC, gbpB, and epsC), sucrose-derived exopolysaccharides (EPS). Consistently, blood strains showed an increased capacity to bind glucan in vitro. Deletion of covR(Sm) in strain UA159 (UA cov) impaired C3b deposition and binding to serum IgG and C-reactive protein (CRP) as well as phagocytosis through C3b/iC3b receptors and killing by neutrophils. Opposite effects were observed in mutants of gbpC, epsC, or gtfBCD (required for glucan synthesis). C3b deposition on UA159 was abolished in C1q-depleted serum, implying that the classical pathway is essential for complement activation on S. mutans. Growth in sucrose-containing medium impaired the binding of C3b and IgG to UA159, UA cov, and blood isolates but had absent or reduced effects on C3b deposition in gtfBCD, gbpC, and epsC mutants. UA cov further showed increased ex vivo survival in human blood in an EPS-dependent way. Consistently, reduced survival was observed for the gbpC and epsC mutants. Finally, UA cov showed an increased ability to cause bacteremia in a rat model."

According to the news reporters, the research concluded: "These results reveal that CovRSm modulates systemic virulence by regulating functions affecting S. mutans susceptibility to complement opsonization."

For more information on this research see: CovR Regulates Streptococcus mutans Susceptibility To Complement Immunity and Survival in Blood. Infection and Immunity, 2016;84(11):3206-3219. Infection and Immunity can be contacted at: Amer Soc Microbiology, 1752 N St NW, Washington, DC 20036-2904, USA. (American Society for Microbiology -
Researchers from State University of New York Provide Details of New Studies and Findings in the Area of Breast Cancer (Clinical outcomes in patients with brain metastases from breast cancer treated with single-session radiosurgery or whole ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Oncology - Breast Cancer have been published. According to news reporting from Buffalo, New York, by NewsRx journalists, research stated, "Gamma Knife radiosurgery (GKRS) is used to treat brain metastases from breast cancer (BMB) as the sole treatment or in conjunction with tumor resection and/or whole brain radiotherapy (WBRT). This study evaluates outcomes in BMB based on treatment techniques and tumor biological features."

The news correspondents obtained a quote from the research from the State University of New York, "The authors reviewed all patients treated with BMB between 2004 and 2014. Patients were identified from a prospectively collected radiosurgery database and institutional tumor registry; 214 patients were identified. Data were collected from aforementioned sources and supplemented with chart review where needed. Independent radiological review was performed for all available brain imaging in those treated with GKRS. Survival analyses are reported using Kaplan-Meier estimates. During the 10-year study period, 214 patients with BMB were treated; 23% underwent GKRS alone, 46% underwent a combination of GKRS and WBRT, and 31% underwent WBRT alone. Median survival after diagnosis of BMB in those treated with GKRS alone was 21 months, and in those who received WBRT alone it was 3 months. In those treated with GKRS plus WBRT, no significant difference in median survival was observed between those receiving WBRT upfront or in a salvage setting following GKRS (19 months vs 14 months, p = 0.63). The median survival of patients with total metastatic tumor volume of <= 7 cm³ versus > 7 cm³ was 20 months vs 7 months (p < 0.001). Human epidermal growth factor receptor-2 (Her-2) positively impacted survival after diagnosis of BMB (19 months vs 12 months, p = 0.03). Estrogen receptor status did not influence survival after diagnosis of BMB. No difference was observed in survival after diagnosis of BMB based on receptor status in those who received WBRT alone. In this single-institution series of BMB, the addition of WBRT to GKRS did not significantly influence..."
survival, nor did the number of lesions treated with GKRS."

According to the news reporters, the research concluded: "Survival after the diagnosis of BMB was most strongly affected by Her-2 positivity and total metastatic tumor volume."

For more information on this research see: Clinical outcomes in patients with brain metastases from breast cancer treated with single-session radiosurgery or whole brain radiotherapy. *Journal of Neurosurgery*, 2016;125():26-30. *Journal of Neurosurgery* can be contacted at: Amer Assoc Neurological Surgeons, 5550 Meadowbrook Drive, Rolling Meadows, IL 60008, USA.

Our news journalists report that additional information may be obtained by contacting D. Prasad, SUNY Buffalo, Jacobs Sch Med, Dept. of Neurosurg, Buffalo, NY, United States. Additional authors for this research include R. Elmarzouky, T. O'Connor, R. Plunkett and D. Prasad.

**Drugs and Therapies - Ophthalmic Antiinfectives**

**Researchers from Stevens Institute of Technology Describe Findings in Ophthalmic Antiinfectives (Extreme Activity of Drug Nanocrystals Coated with A Layer of Non-Covalent Polymers from Self-Assembled Boric Acid)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Drugs and Therapies - Ophthalmic Antiinfectives is now available. According to news reporting from Hoboken, New Jersey, by NewsRx journalists, research stated, "Non-covalent polymers have remarkable advantages over synthetic polymers for wide biomedical applications. In this study, non-covalent polymers from self-assembled boric acid were used as the capping reagent to replace synthetic polymers in drug crystallization."

The news correspondents obtained a quote from the research from the Stevens Institute of Technology, "Under acidic pH, boric acid selfassembled on the surface of drug nanocrystals to form polymers with network-like structures held together by hydrogen bonds. Coating driven by boric acid self-assembly had negligible effects on drug crystallinity and structure but resulted in drug nanocrystals with excellent dispersion properties that aided in the formation of a more stable suspension. Boric acid coating improved drug stability dramatically by preventing drug molecules from undergoing water hydrolysis in a neutral environment. More importantly, the specific reactivity of orthoboric groups to diols in cell glycocalyx facilitated a rapid cross-membrane translocation of drug nanocrystals, leading to efficient intracellular drug delivery, especially on cancer cells with highly expressed sialic acids. Boric acid coated nanocrystals of camptothecin, an anticancer drug with poor aqueous solubility and stability, demonstrated extreme cytotoxic activity (IC50 < 5.0 μg/mL) to cancer cells compared to synthetic polymer coated CPT nanocrystals and free CPT."

According to the news reporters, the research concluded: "Surface coating using non-
covalent polymers from self-assembled boric acid will have wide biomedical applications especially in biomaterials and drug delivery field."

Keywords for this news article include: Hoboken, New Jersey, United States, North and Central America, Genetics, Risk and Prevention, Ophthalmic Antiinfectives, Ophthalmic Compounds, Nanotechnology, Boric Acids, Nanocrystal, Stevens Institute of Technology.

**Aortic Valve Replacement**

**Researchers from Strasbourg University Hospital Report Findings in Aortic Valve Replacement (Impact of Prosthesis-Patient Mismatch on Long-term Functional Capacity After Mechanical Aortic Valve Replacement)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Aortic Valve Replacement have been published. According to news reporting originating from Strasbourg, France, by NewsRx correspondents, research stated, "The impact of prosthesis-patient mismatch (PPM) after aortic valve replacement (AVR) for aortic stenosis on exercise capacity remains controversial. The aim of this study was to analyze the long-term impact of PPM after mechanical AVR on maximal oxygen uptake (VO2max)."

Our news editors obtained a quote from the research from Strasbourg University Hospital, "The study included 75 patients who had undergone isolated mechanical AVR for aortic stenosis with normal left ventricular (LV) function between 1994 and 2012. Their functional capacity was evaluated on average 4.6 years after AVR by exercise testing, including measurement of their VO2max, and by determining their New York Heart Association functional class and Short Form-36 score. Two groups were defined by measuring the patients' indexed effective orifice area (iEOA) by transthoracic echocardiography: a PPM group (iEOA < 0.85 cm(2)/m(2)) and a no-PPM group (iEOA >= 0.85 cm(2)/m(2)). PPM was present in 37.0% of the patients. The percentage of the predicted VO2max achieved was significantly lower in the PPM group (86.7 +/- 19.5% vs 97.5 +/- 23.0% in the no-PPM group; P = 0.04). Compared with the no-PPM group, the PPM group contained fewer patients in New York Heart Association functional class I and their mean Short Form-36 physical component summary score was significantly lower. The mean transvalvular gradient was significantly higher in the PPM group than in the no-PPM group (P < 0.001). Systolic and diastolic function and LV mass had normalized in both groups."

According to the news editors, the research concluded: "PPM is associated in the
long term with moderate but significant impairment of functional capacity, despite optimal LV reverse remodelling and normalization of LV systolic and diastolic function."

The news editors report that additional information may be obtained by contacting H. Kremer, Strasbourg Univ Hosp, Dept. of Cardiac Surg, Strasbourg, France. Additional authors for this research include E. Epailly, M. Velten, J. Radojevic, B. Eisenmann, H. Kremer and M. Kindo.

Oncology - Tongue Cancer

Researchers from Sun Yat Sen University Report Recent Findings in Tongue Cancer (Dysphagia in Tongue Cancer Patients Before and After Surgery)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Oncology - Tongue Cancer are presented in a new report. According to news reporting originating in Guangdong, People's Republic of China, by NewsRx journalists, research stated, "To define factors influencing postoperative aspiration in tongue cancer patients and to analyze the characteristics of dysphagia before and after surgery. A total of 112 tongue cancer patients participated in this work."

The news reporters obtained a quote from the research from Sun Yat Sen University, "Videofluoroscopic swallowing studies were performed in all patients before and after surgery. A Penetration-Aspiration Scale score of 3 or greater was defined as an aspiration risk. Qualitative data were collected on a frame-by-frame basis from each videofluoroscopic swallowing study and analyzed. Smoking (58.14%, P< .01), tongue resection greater than 50% (38.71%, P< .05), and advanced tumor stage (49.18%, P< .01) were strong risk factors for aspiration. High incidences of inadequate tongue movement, delayed oral transit time, reduced hyoid bone elevation, poor aspiration or penetration, vallecula epiglottica, and residual material in the pyriform sinuses were evident after surgery (all P< .001). The Penetration-Aspiration Scale score was significantly higher after surgery than before surgery. The incidence of silent aspiration increased to 6.25% postoperatively. Smoking, larger tongue resection, and advanced tumor stage were strong risk factors for postoperative aspiration and dysphagia complications in tongue cancer patients. The aspiration rate was higher after surgery."

According to the news reporters, the research concluded: "Further studies should
focus on the prevention and early treatment of dysphagia, especially postoperative aspiration, in tongue cancer patients."

Our news correspondents report that additional information may be obtained by contacting W.L. Chen, Sun Yat Sen UniversitySun Yat Sen Mem Hosp, Dept. of Stomatol, Guangzhou, Guangdong, People's Republic of China. Additional authors for this research include W.L. Chen, Z.Q. Huang and Z.H. Yang.

**Oncology - Neuroblastomas**

**Researchers from Sun Yat Sen University Report on Findings in Neuroblastomas (Low dose of arsenic trioxide inhibits multidrug resistant-related P-glycoprotein expression in human neuroblastoma cell line)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Oncology - Neuroblastomas. According to news reporting originating in Guangdong, People's Republic of China, by NewsRx journalists, research stated, "This study investigated arsenic trioxide (As203), cisplatin (DDP) and etoposide (Vp16) on the anticancer effects and P-glycoprotein (P-gp) expression in neuroblastoma (NB) SK-N-SH cells. The potential influence of As2O3, DDP and Vp16 currently included in NB routine treatment protocols on cytotoxicity in SK-N-SH cells was measured by flow cytometry and drug half-maximal inhibitory concentration (IC50) was established."

The news reporters obtained a quote from the research from Sun Yat Sen University, "Moreover, chemotherapeutic agent-mediated changes of cellular expression levels of resistant-related P-gp, was monitored using western blotting. The data showed that As2O3, DDP and Vp16 significantly inhibited the growth and survival of the SK-N-SH cells at different concentration. Notably, the levels of apoptosis were upregulated in SK-N-SH cells with an acceleration of the exposure time and the concentration of As2O3, DDP and Vp16. As2O3, DDP and Vp16 were observed with their IC50 values on SK-N-SH cells being 3]2M, 8 and 100 yg/ml, respectively. Flow cytometry analysis showed that As2O3 at low concentrations in SK-N-SH cells led to enhanced accumulation of cell populations in G2/M phase with increasing the exposure time, and increased levels of apoptosis. In contrast, we observed that SK-N-SH cell
populations arrested in S phase by DDP and Vp16. In vitro examination revealed that following pretreatment of SK-N-SH cells with As2O3, the expression of P-gp was not increased. The expression of P-gp downregulation were noted following the group treated by As2O3 at 2 and 3 JIM. Exposed to As2O3 at 3 JIM for 72 h, SK-N-SH cells exhibited lower expression of P-gp than 2/4M As2O3 for 72 h. In contrast, the expression of P-gp was upregulated by DDP and VP16. In summary, SK-N-SH cells were responsive to chemotherapeutic agent-induced apoptosis in a dose-dependent and time-dependent manner."

According to the news reporters, the research concluded: "In particular, ours findings showed that low dose of As2O3 markedly reduced the P-gp expression and increased apoptotic cell death in human NB cell line."

Our news correspondents report that additional information may be obtained by contacting Y. LI, Sun Yat Sen UniversitySun Yat Sen Mem Hosp, Dept. of Pediat Hematol Oncol, Guangzhou 510120, Guangdong, People's Republic of China. Additional authors for this research include Y. LI, X.L. Xiong, K. Qi, C. Zhang, J.P. Fang and H.X. Guo.

Keywords for this news article include: Guangdong, People's Republic of China, Asia, ATP-Dependent Organic Anion Transporters, ATP-Binding Cassette Transporters, Membrane Transport Proteins, Anion Transport Proteins, Arsenic Trioxide Therapy, Membrane Glycoproteins, Drugs and Therapies, Membrane Proteins, Carrier Proteins, P-Glycoproteins, Glycoconjugates, Drug Resistance, Pharmaceuticals, Antineoplastics, Neuroblastomas, Hematology, Cytometry, Chemicals, Apoptosis, Ion Pumps, Cell Line, Oncology, Sun Yat Sen University.

Our news correspondents obtained a quote from the research from Sunway University, "The rate of development of novel antiacanthamoebic chemotherapies of translational value and the lack of interest of the pharmaceutical industry in developing such chemotherapies have been disappointing. On the other hand, the market for contact lenses/contact lens disinfectants is a multi-billion-dollar industry and has been successful and profitable. A better understanding of drugs, their targets, and mechanisms of action will facilitate the development of more-effective
chemotherapies.

According to the news editors, the research concluded: "Here, we review the progress toward phenotypic drug discovery, emphasizing the shortcomings of useable therapies."

Cyclohexanes

Researchers from Takeda Pharmaceutical Detail New Studies and Findings in the Area of Cyclohexanes (TAK-063, A PHOSPHODIESTERASE 10A INHIBITOR, MODULATES NEURONAL ACTIVITY IN VARIOUS BRAIN REGIONS IN pHMRI AND EEG STUDIES WITH AND WITHOUT ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Cyclohexanes have been published. According to news reporting out of Fujisawa, Japan, by NewsRx editors, research stated. "TAK-063 is a selective phosphodiesterase 10A (PDE10A) inhibitor that produces potent antipsychotic-like and pro-cognitive effects at 0.3 mg/kg (26% PDE10A occupancy in rats) or higher in rodents through the balanced activation of the direct and indirect pathways of striatal medium spiny neurons (MSNs). In this study, we evaluated the specific binding of TAK-063 using in vitro autoradiography (ARG) and the modulation of brain activity using pharmacological magnetic resonance imaging (pHMRI) and electroencephalography (EEG)."

Our news journalists obtained a quote from the research from Takeda Pharmaceutical, "][H-3]TAK-063 significantly accumulated in the caudate-putamen (CPu), ventral pallidum (VP), substantia nigra (SN), hippocampus (Hipp), and amygdala (Amy), but not in the frontal cortex (Fcx), brainstem (Bs), or cerebellum (Cb) in an ARG study using rat brain sections. [H-3]TAK-063 accumulation in the CPu was more than eighteen-fold higher than that in the Hipp and Amy. TAK-063 at 0.3 mg/kg increased the blood oxygenation level-dependent (BOLD) signal in the striatum and Amy, and decreased it in the Fcx in a pHMRI study with anesthetized rats. TAK-063 at 0.3 mg/kg significantly reduced the ketamine-induced increase in EEG gamma power both in awake and anesthetized rats. TAK-063 at 0.2 mg/kg..."
(35% PDE10A occupancy in monkeys) also reduced the ketamine-induced increase in EEG gamma power in awake monkeys. In line with the EEG data, TAK-063 at 0.3 mg/kg reversed the ketamine-induced BOLD signal changes in the cortex, Bs, and Cb in a phMRI study with anesthetized rats.

According to the news editors, the research concluded: "These data suggest that TAK-063 at about 30% PDE10A occupancy modulates activities of multiple brain regions through activation of neuronal circuits in rats and monkeys."

For more information on this research see: TAK-063, A PHOSPHODIESTERASE 10A INHIBITOR, MODULATES NEURONAL ACTIVITY IN VARIOUS BRAIN REGIONS IN phMRI AND EEG STUDIES WITH AND WITHOUT KETAMINE CHALLENGE. Endocrine Cells

Researchers from Tel Aviv University Describe Findings in Endocrine Cells [Impaired function of trophoblast cells derived from translocated hESCs may explain pregnancy loss in women with balanced translocation (11;22)]

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Endocrine Cells are discussed in a new report. According to news reporting originating in Tel Aviv, Israel, by NewsRx journalists, research stated, "The aim of the study was to study whether the trophoblasts carrying unbalanced translocation 11:22 [t(11;12)] display abnormal expression of trophoblastic genes and impaired functional properties that may explain implantation failure. t(11;22) hESCs and control hESCs were differentiated in vitro into trophoblast cells in the presence of BMP4, and trophoblast vesicles (TBVs) were created in suspension. The expression pattern of extravillous trophoblast (EVT) genes was compared between translocated and control TBVs."

Financial support for this research came from Ministry of Health, Israel.

The news reporters obtained a quote from the research from Tel Aviv University, "The functional properties of the TBVs were evaluated by their attachment to endometrium cells (ECC1) and invasion through trans-well inserts. TBVs derived from control hESCs expressed EVT genes from functioning trophoblast cells. In contrast, TBVs differentiated from the
translocated hESC line displayed impaired expression of EVT genes. Moreover, the number of TBVs that were attached to endometrium cells was significantly lower compared to the controls. Correspondingly, invasiveness of trophoblast-differentiated translocated cells was also significantly lower than that of the control cells. These results may explain the reason for implantation failure in couple carriers of t(11;22)."

According to the news reporters, the research concluded: "They also demonstrate that translocated hESCs comprise a valuable in vitro human model for studying the mechanisms underlying implantation failure."

Our news correspondents report that additional information may be obtained by contacting D. Ben-Yosef, Tel Aviv University, Dept. of Cell & Dev Biol, Sackler Fac Med, Tel Aviv, Israel. Additional authors for this research include D. Ben-Yosef and Y. Kalma.

**Lung Diseases and Conditions - Altitude Sickness**

**Researchers from Third Military Medical University Detail New Studies and Findings in the Area of Altitude Sickness (Analysis of High-altitude Syndrome and the Underlying Gene Polymorphisms Associated with Acute Mountain Sickness after a Rapid ...)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Lung Diseases and Conditions - Altitude Sickness is now available. According to news originating from Chongqing, People's Republic of China, by NewsRx correspondents, research stated, "To investigated the objective indicators and potential genotypes for acute mountain sickness (AMS). 176 male subjects were evaluated for symptoms scores and physiological parameters at 3700 m. EPAS1 gene polymorphisms were explored and verified effects of potential genotypes on pulmonary function by inhaled budesonide. The incidence of AMS was 53.98% (95/176)."

Our news journalists obtained a quote from the research from Third Military Medical University, "The individuals who suffered from headache with anxiety and greater changes in heart rate (HR), the forced vital capacity (FVC), and mean flow velocity of basilar artery (Vm-BA), all of which were likely to develop AMS. The rs4953348 polymorphism of EPAS1 gene had a significant correlation with the SaO2 level and AMS, and a significant difference in the AG and GG genotype distribution between the AMS and non-AMS groups. The spirometric parameters were significantly lower, but HR (P = 0.036) and Vm-BA (P = 0.042) significantly
higher in the AMS subjects with the G allele than those with the A allele. In summary, changes in HR (>= 82 beats/min), FVC (<= 4.2 Lt) and Vm-BA (>= 43 cm/s) levels may serve as predictors for diagnosing AMS accompanied by high-altitude syndrome.

According to the news editors, the research concluded: "The A allele of rs4953348 is a protective factor for AMS through HR and Vm-BA compensation, while the G allele may contribute to hypoxic pulmonary hypertension in AMS."

For more information on this research see: Analysis of High-altitude Syndrome and the Underlying Gene Polymorphisms Associated with Acute Mountain Sickness after a Rapid Ascent to High-altitude. Scientific Reports, 2016;6():1-10. Scientific Reports can be contacted at: Nature Publishing Group, Macmillan Building, 4 Crinan St, London N1 9XW, England. Biological Factors - Autacoids

Researchers from Third Military Medical University Report Findings in Autacoids (Xinqin exhibits the anti-allergic effect through the JAK2/STAT5 signaling pathway)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Biological Factors - Autacoids is now available. According to news originating from Chongqing, People's Republic of China, by NewsRx correspondents, research stated, "Ethnopharmacological relevance: Xinqin, a polyherbal medicine, is an important traditional Chinese herbal formula used in traditional oriental medicine for treatment of allergic rhinitis (AR). The formula is based on the Chinese Pharmacopoeia. Aim of the study: Previously, Xinqin exhibited potent anti-allergic effect in a guinea pig model of AR."

Financial support for this research came from National Natural Science Foundation of China.

Our news journalists obtained a quote from the research from Third Military Medical University, "In this study, we explored the molecular mechanism of the anti-allergic effect mediated by Xinqin. AR was induced in guinea pigs (Hartley) with toluene-2, 4-disocyanate (TDI) in vivo and in HMC-1 mast cells with A23187/phorbol 12-myristate-13-acetate (PMA) in vitro. The releases of allergic inflammatory mediators such as histamine, leukotriene (LT) D4, immunoglobulin (Ig) E, TNF-alpha, and IL-6 were analyzed for allergy. The mast cell degranulation was displayed in HMC-1 mast cells. The activities of janus protein kinase 2 (JAK2), signal transduction and activator of transcription 5 (STAT5) and suppressor of cytokine signaling 3 (SOCS3) were evaluated by Western blot. Treatment with Xinqin resulted in AR symptoms and decreases in levels of histamine, LTD4, IgE, TNF-alpha, and IL-6 in serum of guinea pig model of AR and in A23187/PMA-stimulated HMC-1 mast cells. Treatment with
Xinqin also inhibited cell degranulation in A23187/PMA-stimulated HMC-1 mast cells. The JAK2/STAT5 signaling pathway could play an important role in the anti-allergic activity mediated by Xinqin. Xinqin exerts the anti-allergic effect by modulating mast cell-mediated allergic responses by down-regulating JAK2/STAT5 signaling pathway."

According to the news editors, the research concluded: "Results from this study provide a mechanistic basis for the application of Xinqin in the treatment of AR."

The news correspondents report that additional information may be obtained from N. Gao, Third Military Medical University, Coll Pharm, Chongqing, People's Republic of China. Additional authors for this research include Y. Xiong, G.B. Li, Q. Tang, M. Cao, J.B. Huang, M. Xing, C.P. Hu, Y. Gong, Q.H. Wang, N. Gao and R. Zhang.

**Liver Diseases and Conditions - Liver Failure**

**Researchers from Thomas Jefferson University Provide Details of New Studies and Findings in the Area of Liver Failure (Gestational Alloimmune Liver Disease A Devastating Condition Preventable With Maternal Intravenous Immunoglobulin)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Liver Diseases and Conditions - Liver Failure. According to news reporting out of Philadelphia, Pennsylvania, by NewsRx editors, research stated, "Gestational alloimmune liver disease, a form of profound liver failure in the newborn, is the main underlying cause of the entity formerly known as neonatal hemochromatosis. Antepartum maternal intravenous immunoglobulin (IVIG) has been shown to prevent gestational alloimmune liver disease, which otherwise has a recurrence risk above 90% in subsequent pregnancies."

Our news journalists obtained a quote from the research from Thomas Jefferson University, "A 30-year-old woman, gravida 3 para 0120, presented early in gestation. Her previous pregnancy had been complicated by fetal growth restriction, oligohydramnios, and ultimately fatal fulminant neonatal liver failure. With gestational alloimmune liver disease recognized as the primary diagnosis for the liver failure, we began maternal weekly IVIG therapy. She delivered a healthy newborn at term without evidence of hepatic dysfunction."

According to the news editors, the research concluded: "Recognition of gestational alloimmune liver disease enables antepartum treatment that dramatically alters the course of
For more information on this research see: Gestational Alloimmune Liver Disease A Devastating Condition Preventable With Maternal Intravenous Immunoglobulin. Obstetrics and Gynecology, 2016;128(5):1092-1094. Obstetrics and Gynecology can be contacted at: Lippincott Williams & Wilkins, Two Commerce Sq, 2001 Market St, Philadelphia, PA 19103, USA. Oncology - Lymphoma

Researchers from Tianjin Medical University Cancer Institute and Hospital Discuss Findings in Lymphoma (Evaluation of primary thyroid lymphoma by ultrasonography combined with contrast-enhanced ultrasonography: A pilot study)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Oncology - Lymphoma have been presented. According to news reporting originating from Tianjin, People's Republic of China, by NewsRx correspondents, research stated, "To evaluate the features of primary thyroid lymphoma (PTL) by ultrasonography (US) combined with contrast-enhanced ultrasonography (CEUS). In this retrospective study, 20 patients (8 male and 12 female) with PTL were evaluated by conventional US and among them, 10 patients underwent CEUS examination."

Our news editors obtained a quote from the research from Tianjin Medical University Cancer Institute and Hospital, "The appearance of US features was classified into three types: Diffusive mass type, multiple nodular type and mixed type. The CEUS patterns included diffusive homogeneous enhancement and diffusive heterogeneous enhancement pattern. Parameters of CEUS time-intensive curve were analyzed in primary tumor and involved lymph nodes compared to ipsilateral common carotid artery. Of 20 patients with PTL, 18 presented an enlarging neck mass that grew rapidly with an average duration of 3.2 months, and 17 were associated with Hashimoto's thyroiditis. In conventional US, all patients had marked hypoechoic masses. Among them, 12 patients were diffusive mass type, 6 were multiple nodular type and 2 were mixed type. For CEUS patterns, 8 were diffusive homogeneous enhancement and 2 were diffusive heterogeneous enhancement. Necrosis areas were showed in diffuse heterogeneous pattern which were hardly seen in conventional US. In the quantitative analysis of CEUS parameters, the time to peak of time-intensive curve in the primary tumors or involved lymph nodes was longer than that of the ipsilateral common carotid artery (p=0.004). PTL
mainly demonstrated as a diffusive mass type with marked hypoechogenecity on conventional US and diffusive homogeneous enhancement pattern on CEUS."

According to the news editors, the research concluded: "And the heterogeneous enhancement pattern is also helpful for detecting necrosis areas of PTL."

The news editors report that additional information may be obtained by contacting M. Gao, Dept. of Thyroid and Cervical Tumor, Tianjin Medical University Cancer Institute and Hospital, Key Laboratory of Cancer Prevention and Therapy, Tianjin, People's Republic of China. Additional authors for this research include Y. Li, S. Zhang, X. Li and M. Gao.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.4103/0019-509X.178419. This DOI is a link to an online electronic document that is either free or for purchase.

Enzymes and Coenzymes - Glycoside Hydrolases

Researchers from Tianjin University of Science and Technology Report Recent Findings in Glycoside Hydrolases (Multivalent S-sialoside protein conjugates block influenza hemagglutinin and neuraminidase)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Enzymes and Coenzymes - Glycoside Hydrolases are presented in a new report. According to news reporting from Tianjin, People's Republic of China, by NewsRx journalists, research stated, "A new class of S-sialoside Human Serum Albumin (HSA) and Bovine Serum Albumin (BSA) conjugates were prepared to enhance the binding affinity to hemagglutinin (HA) and neuraminidase (NA). The valency of glycoconjugates was controlled by the reaction ratio of the S-sialoside monomer and protein."

Financial supporters for this research include Natural Science Foundation of China, International Science & Technology Cooperation Program of China.

The news correspondents obtained a quote from the research from the Tianjin University of Science and Technology, "Hemagglutination inhibition assay showed that these synthetic glycoproteins have higher affinity to HA than the small clusters of sialosides with lower valency, due to multivalent effect and optimized three dimensional presentation of sialosides on the protein platform. The results of fluorescent NA inhibition assay showed that some of the conjugates have moderate NA inhibitory activity, in comparison to the monomer and low valent conjugates with weak or none inhibitory activity. These synthetic sialylated proteins were not cytotoxic with concentrations up to 100 mu M, since the sialylation did not change the secondary structure of protein."

According to the news reporters, the research concluded: "This new kind of conjugates can be used as lead compounds for antiviral drug design and the construction of
pseudo sialoside-protein conjugates library to investigate the carbohydrate-HA/NA recognition process and a platform for the influenza virus capturing.”

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1016/j.carres.2016.09.017. This DOI is a link to an online electronic document that is either free or for purchase.

**Heart Disorders and Diseases - Heart Disease**

**Researchers from Toho University Ohashi Medical Center Report on Findings in Heart Disease (Ischemic Heart Disease in Patients with End-Stage Kidney Disease)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Heart Disorders and Diseases - Heart Disease have been published. According to news reporting out of Tokyo, Japan, by NewsRx editors, research stated, "It was recently reported that the severity of coronary and carotid atherosclerosis in patients with end-stage kidney disease (ESKD) has improved over the last two decades. However, the frequency of coronary artery events observed at the initiation of dialysis remains high."

Our news journalists obtained a quote from the research from Toho University Ohashi Medical Center, "Recently, 5 different clinical types of acute myocardial infarction (MI) were introduced in the third universal definition of MI. Type 2 MI, known as secondary MI, is a more heterogeneous entity, where a condition other than coronary artery narrowing contributes to an acute imbalance in oxygen supply and demand. In patients with chronic kidney disease, it has been demonstrated that type 2 MI is more common than type 1 MI, which is associated with coronary occlusive disease. It is suspected that patients with ESKD also often have type 2 MI. Factors associated with incremental increases in oxygen demand may cause myocardial ischemia in ESKD. Significant epicardial coronary narrowing might not be a necessary precursor of myocardial ischemia in ESKD."

According to the news editors, the research concluded: "To prevent ischemic heart
disease and improve prognosis in patients with ESKD, we need to pay attention not only to coronary stenotic lesions, but also to the factors associated with the induction of an imbalance in myocardial oxygen supply and demand."

Our news journalists report that additional information may be obtained by contacting Y. Tanaka, Division of Nephrology, Toho University Ohashi Medical Center, Tokyo, Japan. Additional authors for this research include N. Joki and H. Hase.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1159/000441582. This DOI is a link to an online electronic document that is either free or for purchase.

Cardiovascular Diseases and Conditions - Venous...

Researchers from Tongji University Report Details of New Studies and Findings in the Area of Venous Thromboembolism (d-Dimer as a Screening Marker for Venous Thromboembolism After Surgery Among Patients Younger Than 50 With Lower Limb Fractures)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Cardiovascular Diseases and Conditions - Venous Thromboembolism. According to news reporting originating from Shanghai, People's Republic of China, by NewsRx correspondents, research stated, "For the present study, the authors hypothesized that the d-dimer levels would be systematically raised in a postoperative population of patients younger than 50 with lower limb fractures and to define a feasible cutoff value for identification of venous thromboembolism (VTE). Doppler ultrasonography of lower limbs was performed pre- and postoperatively to evaluate for deep vein thrombosis in 150 patients who underwent open reduction and internal fixation (ORIF)."

Our news editors obtained a quote from the research from Tongji University, "Plasma d-dimer levels were assessed 2 days before surgery and on the 3rd, 7th, and 10th days after surgery. Statistical analysis was carried out to define a feasible threshold for the d-dimer levels. Plasma d-dimer levels were found to be systematically raised postoperatively, and they differed between patients with and without VTE significantly. On the third day after surgery, d-dimer levels of more than 3 mg/L indicated VTE with a sensitivity of 88.37% and a specificity of 96.96%, allowing for the definition of a feasible cutoff value. Duration of surgery, duration of tourniquet, ventilation time, and time of postoperative immobility of lower limbs were identified as highly significant risk factors for the development of VTE."

According to the news editors, the research concluded: "Using a threshold of 3 mg/L, the d-dimer levels will screen out VTE with a high degree of sensitivity and specificity in younger patients who have undergone ORIF for lower limb fractures."

The news editors report that additional information may be obtained by contacting M. Cai, Tongji Univ, Shanghai Peoples Hosp 10, Sch Med, Dept. of Orthoped, Shanghai 200072, People's Republic of China. Additional authors for this research include P.F. Zan, J.P. Gong and M. Cai.

**Oncology - Gastric Cancer**

**Researchers from Tongji University School of Medicine Report on Findings in Gastric Cancer (Tumor-suppressive functions of long-chain acyl-CoA synthetase 4 in gastric cancer)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Oncology - Gastric Cancer is now available. According to news reporting originating from Shanghai, People's Republic of China, by NewsRx correspondents, research stated, "Long chain acyl CoA synthetase 4 (ACSL4) is a key enzyme in fatty acid metabolism with marked preference for arachidonic acid (AA). Recent reports have implicated its crucial roles in tumorigenesis."

Financial supporters for this research include National Natural Science Foundation of China, Shanghai Natural Science Foundation of China, Specialized Research Fund for the Doctoral Program of Higher Education, Key Disciplines Group Construction Project of Pudong Health Bureau of Shanghai, Outstanding Leaders Training Program of Pudong Health Bureau of Shanghai, Science and technology commission of Shanghai medical guide Foundations.

Our news editors obtained a quote from the research from the Tongji University School of Medicine, "However in gastric cancer (GC), the expression and function of ACSL4 remain unclear. In the present study, we identified ACSL4 as a potential tumor suppressor in GC. The ACSL4 expression in GC samples was evaluated by real-time PCR and immunohistochemistry. The results indicated that the mRNA and protein levels of ACSL4 were frequently downregulated in cancer tissues compared with the adjacent non-cancerous mucosa control tissues. Cell-based functional assays exhibited that ectopic expression of ACSL4 inhibits cell growth, colony formation and cell migration, whereas ACSL4 knockdown enhanced these effects. In a nude mice model, ACSL4 knockdown also promoted subcutaneous xenografts' growth in vivo. Moreover, western blot analysis revealed that ACSL4 expression had a significant effect on FAK and P21 protein level."
According to the news editors, the research concluded: "These findings suggest that ACSL4 plays a tumor-suppressive role and could be a potential therapeutic target in GC."

The news editors report that additional information may be obtained by contacting X. Ye, Dept. of Oncology, Shanghai East Hospital, Tongji University School of Medicine, Shanghai, 200120, People's Republic of China. Additional authors for this research include Y. Zhang, X. Wang, Y. Li and Y. Gao.

**Oncology - Cancer Risk**

**Researchers from ToxStrategies Describe Findings in Cancer Risk (Inhalation cancer risk assessment of hexavalent chromium based on updated mortality for Painesville chromate production workers)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Oncology - Cancer Risk is the subject of a report. According to news reporting out of Mission Viejo, California, by NewsRx editors, research stated, "The exposure-response for hexavalent chromium (Cr(VI))-induced lung cancer among workers of the Painesville Ohio chromate production facility has been used internationally for quantitative risk assessment of environmental and occupational exposures to airborne Cr(VI). We updated the mortality of 714 Painesville workers (including 198 short-term workers) through December 2011, reconstructed exposures, and conducted exposure-response modeling using Poisson and Cox regressions to provide quantitative lung cancer risk estimates."

Our news journalists obtained a quote from the research from ToxStrategies, "The average length of follow-up was 34.4 years with 24,535 person-years at risk. Lung cancer was significantly increased for the cohort (standardized mortality ratio (SMR)=186; 95% confidence interval (CI) 145-228), for those hired before 1959, those with >30-year tenure, and those with cumulative exposure >1.41 mg/m(3)-years or highest monthly exposures >0.26 mg/m(3). Of the models assessed, the linear Cox model with unlagged cumulative exposure provided the best fit and was preferred. Smoking and age at hire were also significant predictors of lung cancer mortality."

According to the news editors, the research concluded: "Adjusting for these variables, the occupational unit risk was 0.00166 (95% CI 0.000713-0.00349), and the environmental unit risk was 0.00832 (95% CI 0.00359-0.0174), which are 20% and 15% lower, respectively, than values developed in a previous study of this cohort."

For more information on this research see: Inhalation cancer risk assessment of hexavalent chromium based on updated mortality for Painesville chromate production workers.
Researchers from Tsinghua University Report New Studies and Findings in the Area of Hemorrhagic Fever Virus (Molecular basis for the formation of ribonucleoprotein complex of Crimean-Congo hemorrhagic fever virus)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Hemorrhagic Fever Virus. According to news reporting originating in Beijing, People's Republic of China, by NewsRx journalists, research stated, "Negative-sense single-strand RNA (-ssRNA) viruses comprise a large family of pathogens that cause severe human infectious diseases. All-ssRNA viruses encode a nucleocapsid protein (NP) to encapsidate the viral genome, which, together with polymerase, forms a ribonucleoprotein complex (RNP) that is packaged into virions and acts as the template for viral replication and transcription."

Funders for this research include National Natural Science Foundation of China, Ministry of Science and Technology.

The news reporters obtained a quote from the research from Tsinghua University, "In our previous work, we solved the monomeric structure of NP encoded by Crimean-Congo hemorrhagic fever virus (CCHFV), which belongs to the Nairovirus genus within the Bunyaviridae family, and revealed its unusual endonuclease activity. However, the mechanism of CCHFV RNP formation remains unclear, due to the difficulty in reconstructing the oligomeric CCHFV NP-RNA complex. Here, we identified and isolated the oligomeric CCHFV NP-RNA complex that formed in expression cells. Sequencing of RNA extracted from the complex revealed sequence specificity and suggested a potential encapsidation signal facilitating the association between NP and viral genome. A cryo-EM reconstruction revealed the ring-
shaped architecture of the CCHFV NP-RNA oligomer, thus defining the interaction between the head and stalk domains that results in NP multimerization. This structure also suggested a modified gating mechanism for viral genome encapsidation, in which both the head and stalk domains participate in RNA binding."

According to the news reporters, the research concluded: "This work provides insight into the distinct mechanism underlying CCHFV RNP formation compared to other ssRNA viruses."

Our news correspondents report that additional information may be obtained by contacting S.F. Sui, Tsinghua Univ, Beijing Adv Innovat Center Struct Biol, Sch Life Sci, State Key Lab Biomembrane, Beijing 100084, People's Republic of China. Additional authors for this research include B.B. Li, Y. Guo, S. Shen, L. Zhao, P.S. Zhang, Y.N. Sun, S.F. Sui, F. Deng and Z.Y. Lou.

**Biotechnology - Pharmacogenomics**

**Researchers from Tubingen University Hospital Report Recent Findings in Pharmacogenomics (Gene copy number variation analysis reveals dosage-insensitive expression of CYP2E1)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Biotechnology - Pharmacogenomics have been published. According to news reporting originating from Tubingen, Germany, by NewsRx correspondents, research stated, "Gene copy number variants (CNVs) of CYP2E1 have been described but not functionally characterized. Here we investigated effects of CNVs on hepatic and lymphoblastoid CYP2E1 expression."

Our news editors obtained a quote from the research from Tubingen University Hospital, "Using available single-nucleotide polymorphism microarray data and quantitative PCR, CYP2E1 gene duplication and deletion carriers were identified. CYP2E1 mRNA, protein and enzyme activity (chlorzoxazone-6-hydroxylation) phenotypes of CYP2E1 were not associated with gene copy number. Analysis of gene expression in lymphoblastoid cell lines in relation to CNV confirmed this finding in an extrahepatic tissue and for other ethnicities. Further analyses identified a linked haplotype cluster with possible influence on gene expression."
expression. In summary, our data suggest a homeostatic, gene dosage-insensitive regulation of CYP2E1 expression by unknown gene dosage compensation mechanisms. This is in striking contrast to well-known structural variations of CYP2A6 and CYP2D6 that have a strong impact on expression and activity."

According to the news editors, the research concluded: "These findings are important in the context of pharmacogenetic prediction."

For more information on this research see: Gene copy number variation analysis reveals dosage-insensitive expression of CYP2E1. Pharmacogenomics Journal, 2016;16 (6):551-558. Pharmacogenomics Journal can be contacted at: Nature Publishing Group, Macmillan Building, 4 Crinan St, London N1 9XW, England. Peripheral Neuropathy

Researchers from Tufts University Report Recent Findings in Peripheral Neuropathy (Transcobalamin 776C -> G polymorphism is associated with peripheral neuropathy in elderly individuals with high folate intake)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Peripheral Neuropathy have been published. According to news reporting out of Boston, Massachusetts, by NewsRx editors, research stated, "The 776C -> G polymorphism of the vitamin B-12 transport protein transcobalamin gene (TCN2) (rs1801198; Pro259Arg) is associated with a lower holotranscobalamin concentration in plasma. This effect may reduce the availability of vitamin B-12 to tissues even when vitamin B-12 intake is adequate."

Our news journalists obtained a quote from the research from Tufts University, "Clinical outcomes associated with vitamin B-12 insufficiency could potentially be worsened by high folate intake. We determined the association of the TCN2 776C -> G polymorphism and folate intake with peripheral neuropathy in elders with normal plasma concentrations of vitamin B-12. Participants in this cross-sectional study (n = 171) were from a cohort of community-based, home-bound elderly individuals aged >= 60y who underwent an evaluation by physicians including an assessment for peripheral neuropathy. Participants were administered food-frequency and general health status questionnaires, anthropometric measurements were taken, and a fasting blood sample from each subject was collected. Odds of neuropathy were 3-fold higher for GG genotypes than for CC genotypes (OR: 3.33; 95% CI: 1.15, 9.64). When folate intake was >2 times the Recommended Dietary Allowance (800 mu g), GG genotypes had 6.9-fold higher odds of neuropathy than CC genotypes (OR: 6.9; 95% CI: 1.31, 36.36). There was
no difference between the genotypes in the odds of peripheral neuropathy when folate intake was <= 800 µg (OR: 1.5; 95% CI: 0.18, 12.33)."

According to the news editors, the research concluded: "The TCN2 776C -> G polymorphism is associated with increased odds of peripheral neuropathy in the elderly, even with a normal vitamin B-12 status, especially if their folate intake is >2 times the Recommended Dietary Allowance."

Our news journalists report that additional information may be obtained by contacting L. Paul, Tufts University, Jean Mayer Dept. of Agriculture Human Nutr Res Center Aging, Boston, MA 02111, United States. Additional authors for this research include P.R. Bergethon, W.Q. Qiu, T.M. Scott, P.F. Jacques, J. Selhub and L. Paul.

Musculoskeletal Diseases and Conditions -

Researchers from Tulane University Describe Findings in Osteoporosis (Association of 3q13.32 variants with hip trochanter and intertrochanter bone mineral density identified by a genome-wide association study)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Musculoskeletal Diseases and Conditions - Osteoporosis. According to news reporting out of New Orleans, Louisiana, by NewsRx editors, research stated, "We performed a GWAS of trochanter and intertrochanter bone mineral density (BMD) in the Framingham Heart Study and replicated in three independent studies. Our results identified one novel locus around the associated variations at chromosomal region 3q13.32 and replicated two loci at chromosomal regions 3p21 and 8q24."

Funders for this research include National Institutes of Health, National Institutes of Health (US), National Natural Science Foundation of China, Natural Science Foundation of Jiangsu Province.

Our news journalists obtained a quote from the research from Tulane University, "Our findings provide useful insights that enhance our understanding of bone development, osteoporosis, and fracture pathogenesis. Hip trochanter (TRO) and intertrochanter (INT) subregions have important clinical relevance to subtrochanteric and intertrochanteric fractures but have rarely been studied by genome-wide association studies (GWASs). Aiming to identify genomic loci associated with BMD variation at TRO and INT regions, we performed a GWAS utilizing the Framingham Heart Study (FHS, N = 6, 912) as discovery sample and utilized the Women's Health Initiative (WHI) African-American subsample (N = 845), WHI Hispanic subsample (N = 446), and Omaha osteoporosis study (N = 971), for replication. Combining the evidence from both the discovery and the replication samples, we identified one novel locus.
around the associated variations at chromosomal region 3q13.32 (rs1949542, discovery p = 6.16 x 10(-8), replication p = 2.86 x 10(-4) for INT-BMD; discovery p = 1.35 x 10(-7), replication p = 4.16 x 10(-4) for TRO-BMD, closest gene RP11-384F7.1). We also replicated two loci at chromosomal regions 3p21 (rs148725943, discovery p = 6.61 x 10(-7), replication p = 5.22 x 10(-4) for TRO-BMD, closest gene CTNNB1) and 8q24 (rs7839059, discovery p = 2.28 x 10(-7), replication p = 1.55 x 10(-3) for TRO-BMD, closest gene TNFRSF11B) that were reported previously. We demonstrated that the effects at both 3q13.32 and 3p21 were specific to the TRO, but not to the femoral neck and spine. In contrast, the effect at 8q24 was common to all the sites."

According to the news editors, the research concluded: "Our findings provide useful insights that enhance our understanding of bone development, osteoporosis, and fracture pathogenesis."

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1007/s00198-016-3663-y. This DOI is a link to an online electronic document that is either free or for purchase.

Oncology - Head and Neck Cancer

Researchers from Turgut Ozal University Detail New Studies and Findings in the Area of Head and Neck Cancer (Investigation of MACC1 Gene Expression in Head and Neck Cancer and Cancer Stem Cells)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Oncology - Head and Neck Cancer is the subject of a report. According to news reporting out of Ankara, Turkey, by NewsRx editors, research stated, "By investigating the MACC1 gene (metastasis-associated in colon cancer 1) in cancer stem cells (CSC) resistant to chemotherapy and in cancer stem cells (CSC) resistant to chemotherapy and in cancer cells (CS) sensitive to chemotherapy we determined a steady expression in both types of cells in head and neck cancer. In conformity with the result we examined if this gene could be a competitor gene for chemotherapy."
Our news journalists obtained a quote from the research from Turgut Ozal University. "According to literature, the MACC1 gene shows a clear expression in head and neck cancer cells [1]. Here we examined MACC1 expression in CSC and investigated it as a possible biomarker. Our experiments were performed in the UT-SCC-74 in primary head and neck cancer cell line. We examined the MACC-1 gene expression by Real Time PCR from both isolated CSC and CS. Expression of MACC-1 gene of cancer stem cells showed an two-fold increase compared with cancer cells. Based on the positive expression of MACC1 in both CS and CSC, this gene may serve as a potential biomarker in head and neck cancer. By comparing the results of this study with the novel features of MACC1, two important hypotheses could be examined. The first hypothesis is that MACC1 is a possible transcription factor in colon cancer, which influences a high expression of CSC in head and neck and affects the expression of three biomarkers of the CSC control group biomarkers."

According to the news editors, the research concluded: "The second hypothesis is that the positive expression of MACC1 in patients with a malignant prognosis of tongue cancer, which belongs to head and neck cancer types, operates a faster development of CSC to cancer cells."

For more information on this research see: Investigation of MACC1 Gene Expression in Head and Neck Cancer and Cancer Stem Cells. *Clinical and Investigative Medicine*, 2016;39(6):S77-S81. *Clinical and Investigative Medicine* can be contacted at: Canadian Soc Clinical Investigation, Csci Head Office, 774 Echo Drive, Ottawa, On K1S 5N8, Canada.

Our news journalists report that additional information may be obtained by contacting E. Gunduz, Turgut Ozal Univ, Fac Med, Dept. of Med Genet, TR-06170 Ankara, Turkey. Additional authors for this research include H. Sahin, K. Akbas, S. Cigdem and E. Gunduz.

**Drugs and Therapies - Antiinfectives**

**Researchers from URMITE Provide Details of New Studies and Findings in the Area of Antiinfectives [Assessment of oral ivermectin versus shampoo in the treatment of pediculosis (head lice infestation) in rural areas of Sine-Saloum, Senegal]**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Drugs and Therapies - Antiinfectives is the subject of a report. According to news originating from Dakar, Senegal, by NewsRx correspondents, research stated, "Reports of treatment failure and the emergence of resistance to topical head lice treatments have become increasingly common, driving the need for continued development of new therapeutic options for pediculosis. Ivermectin has been proposed as a potential alternative for the treatment of pediculosis but has not been sufficiently evaluated."

Our news journalists obtained a quote from the research from URMITE, "In this study, the effectiveness of oral ivermectin versus shampoo in the treatment of pediculosis in
Senegal was compared. The study was conducted in two neighboring villages of Sine-Saloum, Senegal: Dielmo (ivermectin trial group; 201 female participants) and Ndiop (shampoo trial group; 239 female participants). In the ivermectin group, patients received two doses of oral ivermectin (400 μg/kg body weight; Mectizan®) 7 days apart. In contrast, the shampoo group received a shampoo treatment based on D-phenothrin (0.23%; Hegor®). At the beginning of the study, 70 (34.8%) of 201 participants in the ivermectin group were infested by head lice versus 145 (60.7%) of 239 participants in the shampoo group. At Day 15 post-treatment, the efficacy of the treatment against head lice reached 41/53 (77.4%) in the ivermectin group (53 patients were tested in this group) versus 42/130 (32.3%) in the shampoo group (130 patients were tested in this group) (P < 10^-7). However, 4 (7.5%) of the 53 females in the ivermectin group exhibited probable ivermectin treatment failure, suggesting the emergence of ivermectin-resistant lice.

According to the news editors, the research concluded: "This study demonstrates that oral ivermectin is highly effective for the treatment of pediculosis compared with shampoo, but also suggests that ivermectin resistance may emerge during treatment."

The news correspondents report that additional information may be obtained from D. Raoult, Campus Int Rech IRD UCAD, IRD, URMITE, UMR 198IRD, Dakar, Senegal. Additional authors for this research include G. Diatta, C. Sokhna, J.M. Rolain and D. Raoult.

**Oncology - Lymphoma**

**Researchers from Ulm University Report Details of New Studies and Findings in the Area of Lymphoma (Suppressor of cytokine signaling 1 gene mutation status as a prognostic biomarker in classical Hodgkin lymphoma)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Oncology - Lymphoma is now available. According to news reporting from Ulm, Germany, by NewsRx journalists, research stated, "Suppressor of cytokine signaling 1 (SOCS1) mutations are among the most frequent somatic mutations in classical Hodgkin lymphoma (cHL), yet their prognostic relevance in cHL is unexplored. Here, we performed laser-capture microdissection of Hodgkin/Reed-Sternberg (HRS) cells from tumor samples in a cohort of 105 cHL patients."
The news correspondents obtained a quote from the research from Ulm University, "Full-length SOCS1 gene sequencing showed mutations in 61% of all cases (n=64/105). Affected DNA-motifs and mutation pattern suggest that many of these SOCS1 mutations are the result of aberrant somatic hypermutation and we confirmed expression of mutant alleles at the RNA level. Contingency analysis showed no significant differences of patient-characteristics with HRS-cells containing mutant vs. wild-type SOCS1. By predicted mutational consequence, mutations can be separated into those with non-truncating point mutations ('minor' n=49/64=77%) and those with length alteration ('major'; n=15/64=23%). Subgroups did not differ in clinicopathological characteristics; however, patients with HRS-cells that contained SOCS1 major mutations suffered from early relapse and significantly shorter overall survival (p=0.03). The SOCS1 major status retained prognostic significance in uni-(p=0.016) and multivariate analyses (p=0.005)."

According to the news reporters, the research concluded: "Together, our data indicate that the SOCS1 mutation type qualifies as a single-gene prognostic biomarker in cHL."

Our news journalists report that additional information may be obtained by contacting J.K. Lennerz, Ulm University, Institute of Pathology, Ulm, Germany. Additional authors for this research include K. Hoffmann, A.M. Bubolz, D. Lessel, C. Welke, N. Ruther, A. Viardot and P. Moller.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.18632/oncotarget.4829. This DOI is a link to an online electronic document that is either free or for purchase.

**Veterinary Medicine**

**Researchers from United States Department of Agriculture Report Recent Findings in Veterinary Medicine (Impact of the blood meal on humoral immunity and microbiota in the gut of female Culicoides sonorensis)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Veterinary Medicine have been published. According to news originating from Manhattan, Kansas, by NewsRx correspondents, research stated, "Although Culicoides sonorensis is an important vector of orbiviruses causing significant disease in domestic and wild ruminants in the USA, little is known about factors contributing to midge vector competence. In other vectors such as mosquitoes, interactions among the humoral immune response, microbiota, and ingested pathogens within the vector gut directly impact pathogen survival and therefore vectoring potential."

Our news journalists obtained a quote from the research from the United States Department of Agriculture, "We recently described components of the humoral immune
response in the reference transcriptome for adult female C. sonorensis and analysed their
temporal expression profiles across several dietary states (unfed, blood, or sugar fed). Blood
feeding altered the transcription of several humoral immune components of the Immune
deficiency (Imd), dual-oxidase (DUOX), and Janus Kinase and Signal Transducer and Activator
of Transcription (JAK/STAT) pathways. Genes for immune effectors, such as antimicrobial
peptides, were in particular highly induced. Since blood feeding also stimulated proliferation
and diversification of bacterial populations colonising the gut of female midges, we infer that
changes in immune gene expression were a result of fluctuations in gut microbiota."

According to the news editors, the research concluded: "Thus, diet can indirectly (via
microbiota) impact gut immune status and therefore should be carefully considered in
subsequent studies assessing vector competence in biting midges."

For more information on this research see: Impact of the blood meal on humoral
immunity and microbiota in the gut of female Culicoides sonorensis. Veterinaria Italiana,

The news correspondents report that additional information may be obtained from D.
Nayduch, USDA-ARS, Arthropod-Borne Animal Diseases Research Unit, Center for Grain and
Animal Health Research, Manhattan, Kansas, United States. Additional authors for this research
include D. Erram, M.B. Lee, L. Zurek and C.A Saski.

Researchers from University College Report on Findings in Neural Tube
Defects (Inositol for the prevention of neural tube defects: a pilot
randomised controlled trial)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness
& Wellness Week -- New research on Birth Defects - Neural Tube Defects is the subject of a
report. According to news reporting out of London, United Kingdom, by NewsRx editors,
research stated, "Although peri-conceptional folic acid (FA) supplementation can prevent a
proportion of neural tube defects (NTD), there is increasing evidence that many NTD are FA
non-responsive. The vitamin-like molecule inositol may offer a novel approach to preventing
FA-non-responsive NTD."

Our news journalists obtained a quote from the research from University College,
"Inositol prevented NTD in a genetic mouse model, and was well tolerated by women in a small
study of NTD recurrence. In the present study, we report the Prevention of Neural Tube Defects
by Inositol (PONTI) pilot study designed to gain further experience of inositol usage in human
pregnancy as a preliminary trial to a future large-scale controlled trial to evaluate efficacy of
inositol in NTD prevention. Study subjects were UK women with a previous NTD pregnancy
who planned to become pregnant again. Of 117 women who made contact, ninety-nine proved
eligible and forty-seven agreed to be randomised (double-blind) to peri-conceptional
supplementation with inositol plus FA or placebo plus FA. In total, thirty-three randomised
pregnancies produced one NTD recurrence in the placebo plus FA group (n 19) and no
recurrences in the inositol plus FA group (n 14). Of fifty-two women who declined
randomisation, the peri-conceptional supplementation regimen and outcomes of twenty-two further pregnancies were documented. Two NTD recurred, both in women who took only FA in their next pregnancy. No adverse pregnancy events were associated with inositol supplementation."

According to the news editors, the research concluded: "The findings of the PONTI pilot study encourage a large-scale controlled trial of inositol for NTD prevention, but indicate the need for a careful study design in view of the unwillingness of many high-risk women to be randomised."

Our news journalists report that additional information may be obtained by contacting N.D. Greene, 1Newlife Birth Defects Research Centre, Institute of Child Health, University College London, London WC1N 1EH, UK. Additional authors for this research include K.Y. Leung, V. Gay, K. Burren, K. Mills, L.S. Chitty and A.J Copp. The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1017/S0007114515005322. Oncology - Esophageal Cancer

Researchers from University Health Network Discuss Findings in Esophageal Cancer (Adjuvant sunitinib following chemoradiotherapy and surgery for locally advanced esophageal cancer: a phase II trial)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Oncology - Esophageal Cancer is the subject of a report. According to news originating from Toronto, Canada, by NewsRx correspondents, research stated, "The prognosis for locally advanced esophageal cancer is poor despite the use of trimodality therapy. In this phase II study, we report the feasibility, tolerability and efficacy of adjuvant sunitinib."

Our news journalists obtained a quote from the research from University Health Network, "Included were patients with stage IIa, IIb or III cancer of the thoracic esophagus or gastroesophageal junction. Neoadjuvant therapy involved Irinotecan (65mg/m(2)) + Cisplatin (30mg/m(2)) on weeks 1 and 2, 4 and 5, 7 and 8 with concurrent radiation (50Gy/25 fractions) on weeks 4-8. Sunitinib was commenced 4-13 weeks after surgery and continued for one year. Sixty-one patients were included in the final analysis, 36 patients commenced adjuvant sunitinib. Fourteen patients discontinued sunitinib due to disease recurrence (39%) within the 12-month period, 12 (33%) discontinued due to toxicity, and 3 (8%) requested cessation of therapy. In the overall population, median survival was 26 months with a 2 and 3-year survival rate of 52% and 35%, respectively. The median survival for the 36 patients treated with sunitinib was 35 months and 2-year survival probability of 68%. In a historical control, a prior
phase II study with the same trimodality therapy (n = 43), median survival was 36 months, with a 2-year survival of 67%.

According to the news editors, the research concluded: "Initiation of adjuvant sunitinib is feasible, but poorly tolerated, with no signal of additional benefit over trimodality therapy for locally advanced esophageal cancer."

Keywords for this news article include: Toronto, Ontario, Canada, North and Central America, Clinical Trials and Studies, Tyrosine Kinase Inhibitors, VEGF - VEGFR Inhibitors, Multikinase Inhibitors, Drugs and Therapies, Clinical Research, Esophageal Cancer, VEGFR Inhibitors, Gastroenterology, Antineoplastics, Sunitinib, Oncology, Surgery, Therapy, University Health Network.

Our reports deliver fact-based news of research and discoveries from around the world. Copyright 2017, NewsRx LLC
without previous use of IFN alpha-2b) resulting in cancer death. Patients were asked to trade-off the improvement in 5-year DFS and the IFN-related side effects. Utilities for melanoma recurrence (mean 0.60) were significantly lower than for all IFN alpha-2b toxicity scenarios (mean 0.81-0.90). Patients were willing to tolerate mild-to-moderate and severe toxicity for a 50% and 75% chance of 5-year DFS, respectively. Both utilities and threshold benefits were mostly independent from patient characteristics like gender, income, and social situation. Significant impact was only observed by age and previous personal experience with cancer. On average, German patients were willing to trade even severe IFN alpha-2b toxicity for reducing the rate of melanoma recurrence. This result points out the importance of a relapse-free survival for melanoma patients."

According to the news editors, the research concluded: "The utilities measured in our study can be applied to decision-making processes in clinical trials of new adjuvant drugs."

For more information on this research see: Preferences of German melanoma patients for interferon (IFN) alpha-2b toxicities (the DeCOG "GERMELATOX survey") versus melanoma recurrence to quantify patients' relative values for adjuvant therapy. Drugs and Therapies - Toxicology and Pharmacology

Researchers from University Hospital Describe Findings in Toxicology and Pharmacology (Evaluation of the toxicokinetics and apoptotic potential of ethanol extract from Echinodorus macrophyllus leaves in vivo)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Drugs and Therapies - Toxicology and Pharmacology. According to news reporting originating from Dourados, Brazil, by NewsRx correspondents, research stated, "This study evaluates the toxicological, genotoxic, mutagenic and apoptotic potential of an in vivo assay from Echinodorus macrophyllus extract (EEM). The acute toxicity test used 02 groups (n = 5) of female Wistar rats: negative control group (saline) and experimental group (2000 mg/kg b.w.""

Our news editors obtained a quote from the research from University Hospital, "EEM), both orally administered (gavage) at single doses and monitored for 14 days. To assess the genotoxic, mutagenic and apoptotic potential, 50 male Swiss mice were divided into 5 groups (n = 10): Group I: negative control (saline solution 0.1 ml/10 g b.w.); Group II: positive
control (cyclophosphamide 100 mg/kg b.w.) intraperitoneally administered; groups III-V received EEM at 500, 1000 and 2000 mg/kg b.w., respectively. Groups I, III-V received oral administrations (gavage). The results showed that there was no acute lethality or any signs of acute toxicity, indicating that LD50 is greater than 2000 mg/kg b.w. The groups treated with EEM showed no genotoxic or mutagenic activity and did not induce apoptosis in the liver and kidney."

According to the news editors, the research concluded: "Therefore, EEM showed no acute toxicity and at doses of 500, 1000 and 2000 mg/kg b.w. absence of genotoxicity, mutagenicity and no apoptotic events were observed."

For more information on this research see: Evaluation of the toxicokinetics and apoptotic potential of ethanol extract from Echinodorus macrophyllus leaves in vivo. Regulatory Toxicology and Pharmacology, 2016:82():32-38. Regulatory Toxicology and Pharmacology can be contacted at: Academic Press Inc Elsevier Science, 525 B St, Ste 1900, San Diego, CA 92101-4495, USA. (Elsevier - www.elsevier.com; Regulatory Toxicology and Pharmacology - www.journals.elsevier.com/regulatory-toxicology-and-pharmacology/)

Oncology - Glioblastomas
Researchers from University Hospital Detail New Studies and Findings in the Area of Glioblastomas (Cilengitide in newly diagnosed glioblastoma: biomarker expression and outcome)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Oncology - Glioblastomas have been published. According to news reporting out of Zurich, Switzerland, by NewsRx editors, research stated, "Integrins avb3 and avb5 regulate angiogenesis and invasiveness in cancer, potentially by modulating activation of the transforming growth factor (TGF)-b pathway. The randomized phase III CENTRIC and phase II CORE trials explored the integrin inhibitor cilengitide in patients with newly diagnosed glioblastoma with versus without O6-methylguanine DNA methyltransferase (MGMT) promoter methylation."

Our news journalists obtained a quote from the research from University Hospital, "These trials failed to meet their primary endpoints. Immunohistochemistry was used to assess the levels of the target integrins of cilengitide, avb3 and avb5 integrins, of avb8 and of their putative target, phosphorylation of SMAD2, in tumor tissues from CENTRIC (n=274) and CORE (n=224). avb3 and avb5 expression correlated well in tumor and endothelial cells, but showed little association with avb8 or pSMAD2 levels. In CENTRIC, there was no interaction between the biomarkers and treatment for prediction of outcome. In CORE, higher avb3 levels in tumor cells were associated with improved progression-free survival by central review and with improved overall survival in patients treated with cilengitide.Integrins avb3, avb5 and avb8
are differentially expressed in glioblastoma."

According to the news editors, the research concluded: "Integrin levels do not correlate with the activation level of the canonical TGF-b pathway. avb3 integrin expression may predict benefit from integrin inhibition in patients with glioblastoma lacking MGMT promoter methylation."

For more information on this research see: Cilengitide in newly diagnosed glioblastoma: biomarker expression and outcome. Oncotarget, 2016;7(12):15018-32.

Our news journalists report that additional information may be obtained by contacting M. Weller, Dept. of Neurology, University Hospital Zurich and University of Zurich, Zurich, Switzerland. Additional authors for this research include L.B. Nabors, T. Gorlia, H. Leske, E. Rushing, P. Bady, C. Hicking, J. Perry, Y.K. Hong, P. Roth, W. Wick, S.L. Goodman, M.E. Hegi, M. Picard, H. Moch, J. Straub and R. Stupp.

Autoimmune Diseases and Conditions - Psoriatic…

Researchers from University Hospital Detail New Studies and Findings in the Area of Psoriatic Arthritis [Apremilast, an oral phosphodiesterase 4 inhibitor, in patients with psoriatic arthritis and current skin involvement: a phase III, ...]

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Autoimmune Diseases and Conditions - Psoriatic Arthritis. According to news reporting out of Southampton, United Kingdom, by NewsRx editors, research stated, "To evaluate apremilast treatment in patients with active psoriatic arthritis, including current skin involvement, despite prior therapy with conventional disease-modifying antirheumatic drugs and/or biologic agents. Patients (N=505) were randomised (1:1:1) to placebo, apremilast 20 mg twice daily, or apremilast 30 mg twice daily."

Our news journalists obtained a quote from the research from University Hospital, "Rescue therapy with apremilast was designated at week 16 for placebo patients not achieving 20% improvement in swollen and tender joint counts. At week 24, the remaining placebo patients were then randomised to apremilast 20 mg twice daily or 30 mg twice daily. The efficacy and safety of apremilast were assessed over 52 weeks. At week 16, significantly more patients receiving apremilast 20 mg twice daily (28%) and 30 mg twice daily (41%) achieved 20% improvement in American College of Rheumatology response criteria versus placebo (18%; p=0.0295 and p<0.0001, respectively), and mean decrease in the Health Assessment Questionnaire-Disability Index score was significantly greater with apremilast 30 mg twice daily (-0.20) versus placebo (-0.07; p=0.0073). In patients with baseline psoriasis body surface area involvement (>=)3%, significantly more apremilast 30 mg twice daily patients achieved 50% reduction from baseline Psoriasis Area and Severity Index score (41%) versus placebo (24%; p=0.0098) at week 16. At week 52, observed improvements in these measures demonstrated..."
sustained response with continued apremilast treatment. Most adverse events were mild to moderate in severity; the most common were diarrhoea, nausea, headache and upper respiratory tract infection. Apremilast demonstrated clinically meaningful improvements in psoriatic arthritis and psoriasis at week 16; sustained improvements were seen with continued treatment through 52 weeks."

According to the news editors, the research concluded: "Apremilast was generally well tolerated and demonstrated an acceptable safety profile."

Our news journalists report that additional information may be obtained by contacting C.J. Edwards, NIHR Wellcome Trust Clinical Research Facility, University Hospital Southampton, Southampton, UK. Additional authors for this research include F.J. Blanco, J. Crowley, C.A. Birbara, J. Jaworski, J. Aelion, R.M. Stevens, A. Vessey, X. Zhan and P. Bird.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1136/annrheumdis-2015-207963. This DOI is a link to an online electronic document that is either free or for purchase.

**Anesthesia**

**Researchers from University Hospital Provide Details of New Studies and Findings in the Area of Anesthesia (Anesthetic considerations in HELLP syndrome)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Anesthesia are presented in a new report. According to news reporting from Murcia, Spain, by NewsRx journalists, research stated, "HELLP syndrome (hemolysis, elevated liver enzymes, low platelets) is an obstetric complication with heterogenous presentation and multisystemic involvement. It is characterized by microangiopathic hemolytic anemia, elevated liver enzymes by intravascular breakdown of fibrin in hepatic sinusoids and reduction of platelet circulation by its increased consumption."

The news correspondents obtained a quote from the research from University Hospital, "In terms of these patients' anesthetic management, it is essential to consider some details: (1) effective, safe perioperative management by a multidisciplinary approach, and quick, good communication among clinical specialists to achieve correct patient management; (2) neuroaxial block, particularly spinal anesthesia, is the first choice to do the cesarean if there is only moderate, but not progressive thrombocytopenia; (3) if a general anesthesia is required, it is necessary to control the response to stress produced by intubation, especially in patients with"
either severe high blood pressure or neurological signs, or to prevent major cerebral complications; (4) invasive techniques, e.g., as tracheostomy, arterial, and deep-vein canalization, should be considered; (5) if contraindication for neuroaxial anesthesia exists, rapid sequence intubation with general anesthesia should be regarded as an emergency in patients with full stomach; (6) increased risk of difficult airways should be taken into account. Optimal patient management can be chosen after considering the risks and benefits of each anesthetic technique, and based on good knowledge of these patients' pathophysiological conditions."

According to the news reporters, the research concluded: "Later, close patient monitoring is recommended for potential development of hemorrhagic complications, disseminated intravascular coagulation (DIC), or eclampsia."

Our news journalists report that additional information may be obtained by contacting M. del-Rio-Vellosillo, Dept. of Anesthesia, University Hospital Virgen de la Arrixaca, El Palmar, Murcia, Spain.

Oncology - Gastric Cancer

Researchers from University Hospital Report Details of New Studies and Findings in the Area of Gastric Cancer (Identification of IL11RA and MELK amplification in gastric cancer by comprehensive genomic profiling of gastric cancer cell lines)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Oncology - Gastric Cancer. According to news reporting originating in Belem, Brazil, by NewsRx journalists, research stated, "To identify common copy number alterations on gastric cancer cell lines. Four gastric cancer cell lines (ACP02, ACP03, AGP01 and PG100) underwent chromosomal comparative genome hybridization and array comparative genome hybridization."

The news reporters obtained a quote from the research from University Hospital, "We also confirmed the results by fluorescence in situ hybridization analysis using the bacterial artificial chromosome clone and quantitative real time PCR analysis. The amplification of 9p13.3 was detected in all cell lines by both methodologies. An increase in the copy number of 9p13.3 was also confirmed by fluorescence in situ hybridization analysis. Moreover, the interleukin 11 receptor alpha (IL11RA) and maternal embryonic leucine zipper kinase (MELK) genes, which are present in the 9p13.3 amplicon, revealed gains of the MELK gene in all the cell lines studied. Additionally, a gain in the copy number of IL11RA and MELK was observed in 19.1% (13/68) and 55.9% (38/68) of primary gastric adenocarcinoma samples, respectively."
According to the news reporters, the research concluded: "The characterization of a small gain region at 9p13.3 in gastric cancer cell lines and primary gastric adenocarcinoma samples has revealed MELK as a candidate target gene that is possibly related to the development of gastric cancer."

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.3748/wjg.v22.i43.9506. This DOI is a link to an online electronic document that is either free or for purchase.

Skin Diseases and Conditions - Psoriasis

Researchers from University Hospital Report Details of New Studies and Findings in the Area of Psoriasis (Anti-tumor necrosis factor-alpha therapy improves endothelial function and arterial stiffness in patients with moderate to severe ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Skin Diseases and Conditions - Psoriasis have been published. According to news reporting originating from Santander, Spain, by NewsRx correspondents, research stated, "The aim of the present study was to determine if the use of the anti-tumor necrosis factor (TNF)-alpha monoclonal antibody adalimumab could improve endothelial function and arterial stiffness in patients with moderate to severe psoriasis. This was a prospective study on a series of consecutive patients with moderate to severe psoriasis who completed 6 months of therapy with adalimumab."

Financial support for this research came from Abbvie.

Our news editors obtained a quote from the research from University Hospital, "Patients with history of cardiovascular events, diabetes mellitus, kidney disease, hypertension or body mass index of 35 kg/m(2) or more were excluded. Assessment of endothelial function by brachial artery reactivity measuring flow-mediated endothelial dependent vasodilatation (FMD%), and carotid arterial stiffness by pulse wave velocity (PWV) was performed at the onset of treatment (time 0) and at month 6. Twenty-nine patients were studied. Anti-TNF-alpha adalimumab therapy yielded a significant improvement of endothelial function. The mean +/- standard deviation (SD) FMD% values increased from 6.19 +/- 2.44% at the onset of
adalimumab to 7.46 +/- 2.43% after 6 months of treatment with this biologic agent (P = 0.008). Likewise, following the use of adalimumab, PWV levels decreased from 6.28 +/- 1.04 m/s at the onset of adalimumab to 5.69 +/- 1.31 m/s at 6 months (P = 0.03)."

According to the news editors, the research concluded: "Patients with moderate to severe psoriasis exhibit improvement of endothelial function and arterial stiffness following anti-TNF-alpha therapy. These findings are of potential relevance due to increased risk of cardiovascular disease in patients with severe psoriasis."

The news editors report that additional information may be obtained by contacting M.A. Gonzalez-Gay, Hosp Univ Marques de Valdecilla, Div Rheumatol, Epidemiol Genet & Atherosclerosis Res Grp Syst In, Santander, Spain. Additional authors for this research include A. Corrales, R. Lopez-Mejias, S. Armesto, M.A. Gonzalez-Lopez, I. Gomez-Acebo, B. Ubilla, S. Remuzgo-Martinez, M.C. Gonzalez-Vela, R. Blanco, J.L. Hernandez, J. Llorca and M.A. Gonzalez-Gay.

Prostheses

Researchers from University Hospital Report Findings in Prostheses (Complete Transversal Disc Fracture in a Bjork-Shiley Delrin Mitral Valve Prosthesis 43 Years After Implantation)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Prostheses. According to news reporting from Salamanca, Spain, by NewsRx journalists, research stated, "A patient who underwent previous implantation of a mitral valve replacement with a Bjork-Shiley Delrin (BSD) mitral valve prosthesis during infancy was admitted to our institution 43 years later after an episode of syncope and cardiac arrest. Under extreme hemodynamic instability, a mitral valve prosthetic dysfunction causing massive mitral regurgitation was identified."

The news correspondents obtained a quote from the research from University
Hospital, "The patient underwent an emergent cardiac operation, and a complete disc fracture with partial disc migration was found. Exceptional cases of mechanical prosthetic heart valve fracture exist."

According to the news reporters, the research concluded: "We report the first case of complete transversal disc rupture of a BSD mitral valve prosthesis after the longest period of implantation ever reported in that position."

Our news journalists report that additional information may be obtained by contacting M.E. Arnaiz-Garcia, Univ Hosp Salamanca, Dept. of Cardiol, Intens Med Care Unit, Salamanca, Spain. Additional authors for this research include M.E. Arnaiz-Garcia, M.J. Dalmau-Sorli, J.A. Sastre-Rincon, J. Hernandez-Hernandez, M.E. Perez-Losada, V. Sagredo-Meneses and J. Lopez-Rodriguez.

**Immune System Diseases and Conditions - HIV/AIDS**

**Researchers from University Nova of Lisboa Detail New Studies and Findings in the Area of HIV/AIDS (HIV-1 Nef Impairs the Formation of Calcium Membrane Territories Controlling the Signaling Nanoarchitecture at the Immunological Synapse)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Immune System Diseases and Conditions - HIV/AIDS. According to news reporting out of Lisbon, Portugal, by NewsRx editors, research stated, "The ability of HIV-1 to replicate and to establish long-term reservoirs is strongly influenced by T cell activation. Through the use of membrane-tethered, genetically encoded calcium (Ca2+) indicators, we were able to detect for the first time, to our knowledge, the formation of Ca2+ territories and determine their role in coordinating the functional signaling nanostructure of the synaptic membrane."

Our news journalists obtained a quote from the research from the University Nova of Lisboa, "Consequently, we report a previously unknown immune subversion mechanism involving HIV-1 exploitation, through its Nef accessory protein, of the interconnectivity among three evolutionarily conserved cellular processes: vesicle traffic, signaling compartmentalization, and the second messenger Ca2+. We found that HIV-1 Nef specifically associates with the traffic regulators MAL and Rab11b compelling the vesicular accumulation of Lck. Through its association with MAL and Rab11b, Nef co-opts Lck switchlike function
driving the formation Ca2+ membrane territories, which, in turn, control the fusion of LAT-transporting Rab27 and Rab37 vesicles and the formation of LAT nanoclusters at the immunological synapse. Consequently, HIV-1 Nef disengages TCR triggering from the generation of p-LAT and p-SLP nanoclusters driving TCR signal amplification and diversification."

According to the news editors, the research concluded: "Altogether our results indicate that HIV-1 exploits the interconnectivity among vesicle traffic, Ca2+ membrane territories, and signaling nanoclusters to modulate T cell signaling and function."

For more information on this research see: HIV-1 Nef Impairs the Formation of Calcium Membrane Territories Controlling the Signaling Nanoarchitecture at the Immunological Synapse. *Journal of Immunology*, 2016;197(10):4042-4052. *Journal of Immunology* can be contacted at: Amer Assoc Immunologists, 9650 Rockville Pike, Bethesda, MD 20814, USA. **Oncology - Pancreatic Cancer**

**Researchers from University Teaching Hospital Provide Details of New Studies and Findings in the Area of Pancreatic Cancer (Second-line therapy for advanced pancreatic cancer: evaluation of prognostic factors and review of current literature)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Oncology - Pancreatic Cancer. According to news originating from Pisa, Italy, by NewsRx correspondents, research stated, "FOLFIRINOX is a standard first-line treatment for advanced pancreatic cancer (aPC) and no accepted second-line regimen exists. We enrolled 71 aPC patients progressed to modified FOLFIRINOX (mFOLFIRINOX) treated with second-line chemotherapy."

Our news journalists obtained a quote from the research from University Teaching Hospital, "Five partial responses (7.1%) and 19 (27.1%) disease stabilizations were reported. After a median follow-up of 20.1 months, median progression-free survival was 2.5 months (95% CI: 2.1-2.9 months) and median overall survival was 6.2 months (95% CI: 5.3-7.1
months). At multivariate analysis, CA19.9 level (≥) 59 upper normal limit resulted associated with worse survival (hazard ratio: 2.32; 95% CI: 1.12-4.78; p=0.023). Salvage chemotherapy could be useful for a subgroup of aPC patients.

According to the news editors, the research concluded: "Prognostic factors might be helpful to identify patients with greater benefit."

The news correspondents report that additional information may be obtained from C. Caparello, Polo Oncologico, Azienda Ospedaliero-Universitaria Pisana, Istituto Toscano Tumori, Pisa, Italy. Additional authors for this research include C. Vivaldi, L. Fornaro, G. Musettini, G. Pasquini, S. Catanese, G. Masi, M. Lencioni, A. Falcone and E. Vasile.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.2217/fon.16.16. This DOI is a link to an online electronic document that is either free or for purchase.

Drugs and Therapies - Chymotrypsin Therapy

Researchers from University of Adelaide Report New Studies and Findings in the Area of Chymotrypsin Therapy (New Peptidomimetic Boronates for Selective Inhibition of the Chymotrypsin-like Activity of the 26S Proteasome)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Drugs and Therapies - Chymotrypsin Therapy. According to news originating from Adelaide, Australia, by NewsRx correspondents, research stated, "Proteasome is a large proteinase complex that degrades proteins via its three catalytic activities. Among these activities, the 'chymotrypsin-like' activity has emerged as the focus of drug discovery in cancer therapy."

Financial support for this research came from Australian Research Council.

Our news journalists obtained a quote from the research from the University of Adelaide, "Here, we report new peptidomimetic boronates that are highly specific for the chymotrypsin-like catalytic activity of the proteasome. These new specific proteasome inhibitors were demonstrated to have higher in vitro potency and selective cytotoxicity for cancer cells compared to benchmark proteasome inhibitors: bortezomib and carfilzomib."

According to the news editors, the research concluded: "In breast cancer cell lines, treatment with la or 2a induced accumulation of the high molecular weight polyubiquitinated proteins at similar levels observed for bortezomib and carfilzomib, indicating that cancer cell death caused by la/2a is chiefly due to proteasome inhibition."

For more information on this research see: New Peptidomimetic Boronates for Selective Inhibition of the Chymotrypsin-like Activity of the 26S Proteasome. ACS Medicinal Chemistry Letters, 2016;7(12):1039-1043. ACS Medicinal Chemistry Letters can be contacted
Researchers from University of Agriculture Detail New Studies and Findings in the Area of Trimethyl Ammonium Compounds (Choline supplementation alleviates fluoride-induced testicular toxicity by restoring the NGF and MEK expression in mice)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Trimethyl Ammonium Compounds. According to news reporting originating in Shanxi, People's Republic of China, by NewsRx journalists, research stated, "Fluoride is known to cause male reproductive toxicity, and the elucidation of its underlying mechanisms is an ongoing research focus in reproductive toxicology and epidemiology. Choline, an essential nutrient, has been extensively studied for its benefits in nervous system yet was rarely discussed for its prospective effect in male reproductive system."

Financial supporters for this research include China National Natural Science Foundation, Specialized Research Fund for the Doctoral Program of Higher Education of China, Science and Technology Program of Shanxi Province, Program for Top Young Academic Leaders of Higher Institutions of Shanxi.

The news reporters obtained a quote from the research from the University of Agriculture, "This study aims to explore the potential protective role of choline against NaF-induced male reproductive toxicity via MAPK pathway. The male mice were administrated by 150 mg/L NaF in drinking water, 5.75 g/kg choline in diet, and their combination respectively from maternal gestation to postnatal 15 weeks. The results showed that fluoride exposure reduced body weight growth, lowered sperm count and survival percentages, altered testicular histology, down-regulated the mRNA expressions of NGF, Ras, Raf, and MEK genes in testes, as well as significantly decreased the expressions of both NGF and phosphor-MEK proteins in testes. Examination of data from choline-treated mice revealed that choline supplementation ameliorated these fluoride-induced changes. Taken together, our findings suggest that choline supplementation alleviates fluoride-induced testicular toxicity by restoring the NGF and phosphor-MEK expression."
According to the news reporters, the research concluded: "The suitable dosage and supplementation periods of choline await further exploration."

For more information on this research see: Choline supplementation alleviates fluoride-induced testicular toxicity by restoring the NGF and MEK expression in mice. *Toxicology and Applied Pharmacology*, 2016;310():205-214. *Toxicology and Applied Pharmacology* can be contacted at: Academic Press Inc Elsevier Science, 525 B St, Ste 1900, San Diego, CA 92101-4495, USA. (Elsevier - wwwElseviercom; Toxicology and Applied Pharmacology - wwwjournalselseviercom/toxicologyandappliedpharmacology/)

Oncology - Cancer Risk

**Researchers from University of Alabama Discuss Findings in Cancer Risk (Metabolic risk factors and mechanisms of disease in epithelial ovarian cancer: A review)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Oncology - Cancer Risk is the subject of a report. According to news reporting originating in Birmingham, Alabama, by NewsRx journalists, research stated, "Epithelial ovarian cancer continues to be the deadliest gynecologic malignancy. Patients with both diabetes mellitus and obesity have poorer outcomes, yet research correlating metabolic abnormalities, such as metabolic syndrome, to ovarian cancer risk and outcomes is lacking."

The news reporters obtained a quote from the research from the University of Alabama, "This article reviews the literature regarding metabolic derangements and their relationship to epithelial ovarian cancer, with a focus on potential mechanisms behind these associations. PubMed and Google Scholar were searched for articles in the English language regarding epithelial ovarian cancer, obesity, diabetes mellitus, and metabolic syndrome, with a focus on studies conducted since 1990. Obesity, type II diabetes mellitus, and metabolic syndrome have been associated with poor outcomes in epithelial ovarian cancer. More studies investigating the relationship between metabolic syndrome and epithelial ovarian cancer are needed. A variety of pathologic factors may contribute to cancer risk in patients with metabolic derangements, including altered adipokine and cytokine expression, altered immune responses to tumor cells, and changes in pro-tumorigenic signaling pathways."

According to the news reporters, the research concluded: "More research is needed to
examine the effects of metabolic syndrome on epithelial ovarian cancer risk and mortality, as well as the underlying pathophysiologies in patients with obesity, diabetes mellitus, and metabolic syndrome that may be targeted for therapeutic intervention."

For more information on this research see: Metabolic risk factors and mechanisms of disease in epithelial ovarian cancer: A review. Gynecologic Oncology, 2016;143(3):674-683. Gynecologic Oncology can be contacted at: Academic Press Inc Elsevier Science, 525 B St, Ste 1900, San Diego, CA 92101-4495, USA. **Drugs and Therapies - Antineoplastics**

**Researchers from University of Alexandria Describe Findings in Antineoplastics (HPLC Methods for Quantitation of Exemestane-Luteolin and Exemestane-Resveratrol Mixtures in Nanoformulations)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Drugs and Therapies - Antineoplastics. According to news reporting originating in Alexandria, Egypt, by NewsRx journalists, research stated, "Two HPLC-DAD assays for the simultaneous quantitation of exemestane (EXE) and resveratrol (RES)-Mix 1-and EXE and luteolin (LUT)-Mix 2-in novel breast cancer therapy nanoformulations were developed. Calibration curves 15-30 μg/mL and samples were injected through an Inertsil ODS-3 (250 x 4.6 mm, 5 μm) column."

The news reporters obtained a quote from the research from the University of Alexandria, "The gradient elution for Mix 1 was methanol: 0.05% (v/v) acetic acid in water (60: 40 to 80:20, linear over 2 min), and for Mix 2, it was methanol: water (60: 40 for 4 min, then ramped linearly to 90:10, over 12 min) pumped at 1.5 mL/min for 4 min, then 1 mL/min till the end of run. EXE, RES, LUT and flutamide (internal standard (IS)) were measured at 246, 307, 350 and 300 nm, respectively. For Mix 1, RES, EXE and IS eluted at 3.5, 6.8 and 7.4 min, respectively, while for Mix 2, LUT, EXE and IS eluted at 7.5, 11.4 and 12.7 min, respectively. The mean r(2) for the standard curves was >= 0.99, and percentage coefficient of variation and % error of the mean were <2. Both assays successfully quantitated Mix 1 and Mix 2 in their nanoformulations."
According to the news reporters, the research concluded: "The two developed assays were sensitive and selective for the analysis of EXE-LUT and EXE-RES mixtures in nanoformulations according to International Conference on Harmonization guidelines."

Our news correspondents report that additional information may be obtained by contacting D.A. Hamdy, University of Alexandria, Fac Pharm, Pharmaceut Analyt Chem Department, Alexandria 21521, Egypt. Additional authors for this research include A.O. Elzoghby, N.A. Elgindy and D.A. Hamdy.

Keywords for this news article include: Alexandria, Egypt, Africa, Aromatase Inhibitors, Drugs and Therapies, Exemestane Therapy, Pharmaceuticals, Antineoplastics, Hormones, University of Alexandria.

**Nursing - Clinical Nursing**

**Researchers from University of Alicante Report Recent Findings in Clinical Nursing (Comparison of menstrual disorders in hospital nursing staff according to shift work pattern)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Nursing - Clinical Nursing is the subject of a report. According to news reporting out of Alicante, Spain, by NewsRx editors, research stated, "Aim and objective. To assess the association between work in a rotating shift schedule and menstruation characteristics among nurse staff in a prospective study."

Our news journalists obtained a quote from the research from the University of Alicante, "Rotating shifts have been linked to alterations in the reproductive cycle. In the case of menstrual alterations, the conclusions are not clear. Prospective epidemiological study with follow-up over four months. All the female nurse staff (< 40 years) in a hospital were interviewed, collecting sociodemographic and employment information. They were given a menstrual diary to keep a record of their shifts and characteristics of their menstruation (duration, amount of blood, dysmenorrhoea). They had two types of shifts: (1) Rotating shift schedule (two mornings, two afternoons, one night and two days off) including morning shifts (8:00-15:00), afternoon/evening shifts (15:00-22:00) and night shifts (22:00-8:00), and (2) Day shift schedule including morning shifts (8:00-15:00) and/or afternoon/evening shifts (15:00-22:00). The crude and adjusted odds ratios with 95% confidence interval were calculated using logistic generalised estimating equations (GEE) taking into account the correlations of multiple cycles per worker. One hundred and thirteen workers on the rotating shift and 75 on the day shift participated, and information from 730 menstrual cycles were obtained. There were no differences in prolonged duration, dysmenorrhoea, prolonged duration dysmenorrhoea and excessive bleeding among nurses on rotating shift compared to those on the day shift. For prolonged duration of menstruation, workers with more than five years on the rotating shift showed a slightly lower (nonsignificant) risk compared with those with < 5 years. Nurse staff on
the rotating shift did not show increased risk of having menstrual disorders comparing with day staff. Relevance to clinical practice."

According to the news editors, the research concluded: "Shifts with short rotation cycles and a progressive sequence do not appear to cause menstrual disorders in nurse staff who work rotating shifts."

Our news journalists report that additional information may be obtained by contacting E. Ronda-Perez, University of Alicante, Dept. of Community Nursing Prevent Med & Public Hlth &. Alicante, Spain. Additional authors for this research include J.M. Martinez, V. Baste, B.E. Moen and E. Ronda-Perez.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1111/jocn.13371. This DOI is a link to an online electronic document that is either free or for purchase.

Digestive System Diseases and Conditions...

Researchers from University of Amsterdam Provide Details of New Studies and Findings in the Area of Pancreatitis (Clinical outcomes and prevalence of cancer in patients with possible groove pancreatitis)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Digestive System Diseases and Conditions - Pancreatitis. According to news reporting from Amsterdam, Netherlands, by NewsRx journalists, research stated, "Data on non-surgical treatment of groove pancreatitis (GP) and the risk of cancer are lacking. We aimed to determine the prevalence and predictors of cancer in patients in whom the diagnosis GP was considered, and to evaluate symptom improvement after treatment."

The news correspondents obtained a quote from the research from the University of Amsterdam, "Patients referred with possible GP (2001-2014) were retrospectively included. An experienced radiologist reassessed imaging. GP patients received questionnaires evaluating their symptoms. From the 38 possible GP patients, 10 had cancer (26%) and 28 GP (74%). Compared with cancer patients, GP patients more frequently had cysts (2/10 vs. 18/28, P = 0.03), less often jaundice (6/10 vs 3/27, P< 0.01), an abrupt caliber change of the CBD (5/10 vs. 2/28, P< 0.01) or suspicious cytology (5/9 vs 2/20, P = 0.02). Of the 28 GP patients, 14 patients were treated conservatively of whom 12 reported symptom improvement after a median follow-up of 45 months (range 7-127 months). All 6 patients treated endoscopically and 7/8 patients treated surgically reported symptom improvement. Surgery, performed because of treatment failure (3/8) or inability to exclude malignancy (5/8), caused mortality in 1/8 patients. Suspicion of pancreatic cancer should be high in patients presenting with possible GP."
According to the news reporters, the research concluded: "Conservative, endoscopic and surgical treatment can all lead to symptom improvement, suggesting a 'step-up approach' to GP once cancer is excluded."

Our news journalists report that additional information may be obtained by contacting M.G. Besselink, University of Amsterdam, Academy Med Center, Dept. of Surg, Amsterdam, Netherlands. Additional authors for this research include C.Y. Nio, Y. Issa, P. Fockens, J. Verheij, O.R. Busch, T.M. van Gulik, E.A. Rauws, M.A. Boermeester, J.E. van Hooft and M.G. Besselink.

Keywords for this news article include: Amsterdam, Netherlands, Europe, Digestive System Diseases and Conditions, Pancreatic Diseases and Conditions, Cancer, Risk and Prevention, Gastroenterology, Pancreatitis, Oncology, University of Amsterdam.

*Catheterization*

**Researchers from University of Ataturk Report on Findings in Catheterization (Should we change the cannulation site for right subclavian artery cannulation? An experimental study with a newly designed cannula)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Catheterization have been published. According to news reporting out of Izmir, Turkey, by NewsRx editors, research stated, "In this experimental study, we primarily aimed to show the hemodynamic effects and superiority of this newly designed cannula for perfusion compared to standard subclavian cannulation. The new cannula (Figure 1) allows bidirectional axial flow and it directly fits in the brachiocephalic trunk (innominate artery)."

Our news journalists obtained a quote from the research from the University of Ataturk, "We used a cardiopulmonary bypass roller pump, reservoir, 3/8-I/2-I/4-inch Y-connectors and tubing set. Lines were set as seen in Figures 2, 3, 4 and 5. The anatomy of the aorta (ascending, arch, branches, descending) was mimicked, using tubing sets with different sizes and the connectors yielding similar angles and configurations. In this experimental vascular system, systemic vascular resistance was created with partial clamping of the common tubing set. The cannulation sites were created in the subclavian artery and the innominate artery. Perfusion was established with the same pump rate and the same occlusion pressures (systemic vascular resistance). The pressure readings were obtained in the right carotid artery, the left carotid artery and the left subclavian artery. These experimental models of vasculature allowed us to measure pressures-in the carotid system for different cannulation set-ups, using both our newly designed double-outflow cannula, which was introduced via the innominate artery, and the standard arterial cannula, which was introduced via the subclavian artery. Higher pressure
recordings were obtained in the carotid system with the new cannula introduced through innominate artery."

According to the news editors, the research concluded: "Higher cerebral perfusion readings were obtained with our newly designed bidirectional cannula introduced via the innominate artery compared to standard cannulation through the right subclavian artery."

For more information on this research see: Should we change the cannulation site for right subclavian artery cannulation? An experimental study with a newly designed cannula. Perfusion-Uk, 2016;31(8):668-675. Perfusion-Uk can be contacted at: Sage Publications Ltd, 1 Olivers Yard, 55 City Road, London EC1Y 1SP, England.

Our news journalists report that additional information may be obtained by contacting H. Cakir, Izmir Katip Celebi Univ Ataturk Educ & Training H, Dept. of Cardiovasc Surg, Izmir, Turkey. Additional authors for this research include M. Kestelli, I. Yurekli, B. Eygi, S. Iscan, Y. Sac, K. Asar and H. Ogut.

Transplant Medicine - Kidney Transplants

Researchers from University of Barcelona Detail New Studies and Findings in the Area of Kidney Transplants (Effect of mammalian target of rapamycin inhibitors on cytomegalovirus infection in kidney transplant recipients receiving polyclonal ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Transplant Medicine - Kidney Transplants have been presented. According to news originating from Barcelona, Spain, by NewsRx correspondents, research stated, "Mammalian target of rapamycin inhibitors (mTORi) prevents cytomegalovirus (CMV) infection in kidney transplant (KT) patients. From May 2010 to December 2013, all KT recipients were retrospectively analysed."

Our news journalists obtained a quote from the research from the University of Barcelona, "Maintenance immunosuppression regimen was divided into mTORi or calcineurin inhibitors (CNI)-based regimen. Since June 2011, CMV-seropositive recipients (R+) treated with high-intensity immunosuppression and mTORi did not receive anti-CMV prophylaxis. We analysed 350 consecutive patients, of which 95 (27%) received mTORi and 255 (73%) CNI-based immunosuppression. A Cox-regression multivariate analysis showed that the use of mTORi-based immunosuppression during all follow-up reduced the risk of CMV infection (HR 0.36, 95% CI 0.15-0.89, P = 0.028) and confirmed in a propensity score-matched cohort (HR 0.4, 95% CI 0.1-0.9, P = 0.047). Early discontinuation of mTORi increased the risk of CMV infection (HR 3.2; 95% CI 1.7-6.0) in univariate analysis. The incidence of CMV infection was not higher among CMV R+ patients on mTORi and requiring high-intensity immunosuppression when CMV prophylaxis was not given. The use of mTORi protected for CMV infection in KT patients, allowing to avoid antiviral prophylaxis for R+ patients receiving high-intensity immunosuppression."

According to the news editors, the research concluded: "The increased risk of CMV

**Autoimmune Diseases and Conditions - Rheumatoid...**

**Researchers from University of Bari Report on Findings in Rheumatoid Arthritis (Early clinical response predicts low disease activity at one year in rheumatoid arthritis patients on treatment with certolizumab in real-life settings. An ...)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Autoimmune Diseases and Conditions - Rheumatoid Arthritis have been published. According to news reporting from Bari, Italy, by NewsRx journalists, research stated, "The aim of this study was to assess whether good EULAR response assessed at 3 months may predict the achievement of low disease activity (LDA) at 1 year in rheumatoid arthritis (RA) patients on treatment with certolizumab pegol (CZP). From the nationwide Italian registry, we analysed 278 RA patients (age 54.8 +/- 12 years, duration of disease 9.8 +/- 8 years, female 84%) initiating CZP as first line (68%) or >= second line (32%) of biological treatment because of their active disease."

The news correspondents obtained a quote from the research from the University of Bari, "Assessment of disease activity was based on 28 joint Disease Activity Score (DAS28). A reduction of DAS28 > 1.2 (good EULAR response) was assessed at 3 months, and the achievement of LDA (DAS28 <= 3.2) was evaluated at 1 year. Multiple regression models were used to estimate predictors of early good EULAR response or LDA. The percentages of patients attaining good EULAR response were 52% at 3, 65% at 6, and 66% at 12 months. Furthermore, 51.2% (98/192) of the patients reached LDA at 12 months. Patients taking CZP as first biological treatment had adjusted odds ratios (OR) of good EULAR response at 3 months 6 folds higher than in those with >= 1 prior biological drug (OR 6.7, 95% CI 1.97-23.1). While,
the strongest variable correlating with 12 months LDA was the achievement of good EULAR response at 3 months (OR 11.3, 95% CI 13.1-34.8)."

According to the news reporters, the research concluded: "Our findings showed that attaining good EULAR response at 3 months strongly predicted 1 year LDA in RA patients treated with CZP in real-life settings."

Our news journalists report that additional information may be obtained by contacting F. Iannone, University of Bari, Policlinico, Rheumatol Unit, I-70124 Bari, Italy. Additional authors for this research include G. Carlino, A. Marchesoni, P. Sarzi-Puttini, R. Gorla and G. Lapadula.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1016/j.jbspin.2015.12.004. This DOI is a link to an online electronic document that is either free or for purchase.

**Immunology**

**Researchers from University of Basel Discuss Findings in Immunology (T-cell metabolism governing activation, proliferation and differentiation; a modular view)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Immunology is now available. According to news reporting out of Basel, Switzerland, by NewsRx editors, research stated, "T lymphocytes are a critical component of the adaptive immune system mediating protection against infection and malignancy, but also implicated in many immune pathologies. Upon recognition of specific antigens T cells clonally expand, traffic to inflamed sites and acquire effector functions, such as the capacity to kill infected and malignantly transformed cells and secrete cytokines to coordinate the immune response."

Funders for this research include National Science Foundation, Gebert Ruf Stiftung, Swiss Cancer League.

Our news journalists obtained a quote from the research from the University of Basel, "These processes have significant bioenergetic and biosynthetic demands, which are met by dynamic changes in T-cell metabolism, specifically increases in glucose uptake and metabolism; mitochondrial function; amino acid uptake, and cholesterol and lipid synthesis. These metabolic changes are coordinate by key cellular kinases and transcription factors. Dysregulated T-cell metabolism is associated with impaired immunity in chronic infection and
cancer and conversely with excessive T-cell activity in autoimmune and inflammatory pathologies."

According to the news editors, the research concluded: "Here we review the key aspects of T-cell metabolism relevant to their immune function, and discuss evidence for the potential to therapeutically modulate T-cell metabolism in disease."

For more information on this research see: T-cell metabolism governing activation, proliferation and differentiation; a modular view. *Immunology*, 2017;150(1):35-44.

Our news journalists report that additional information may be obtained by contacting C. Hess, University of Basel, Dept. of Biomed, Immunobiol Lab, CH-4031 Basel, Switzerland. Additional authors for this research include A.V. Burgener, J. Grahlert and C. Hess.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1111/imm.12655. This DOI is a link to an online electronic document that is either free or for purchase.

**Clinical Research - Clinical Trials and Studies**

**Researchers from University of Bern Discuss Findings in Clinical Trials and Studies (Cerebral Microembolization During Aortic Valve Replacement Using Minimally Invasive or Conventional Extracorporeal Circulation: A Randomized Trial)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Clinical Research - Clinical Trials and Studies are presented in a new report. According to news originating from Bern, Switzerland, by NewsRx correspondents, research stated, "To compare intraoperative cerebral microembolic load between minimally invasive extracorporeal circulation (MiECC) and conventional extracorporeal circulation (CECC) during isolated surgical aortic valve replacement (SAVR), we conducted a randomized trial in patients undergoing primary elective SAVR at a tertiary referral hospital. The primary outcome was the procedural phase-related rate of high-intensity transient signals (HITS) on transcranial Doppler ultrasound."

Our news journalists obtained a quote from the research from the University of Bern, "HITS rate was used as a surrogate of cerebral microembolism in pre-defined procedural phases in SAVR using MiECC or CECC with (+F) or without (-F) an oxygenator with integrated arterial filter. Forty-eight patients were randomized in a 1:1 ratio to MiECC or CECC. Due to intra procedural Doppler signal loss (n=3), 45 patients were included in final analysis. MiECC perfusion regimen showed a significantly increased HITS rate compared to CECC (by a factor of 1.75; 95% confidence interval, 1.19-2.56). This was due to different HITS rates in procedural phases from aortic cross-clamping until declamping [phase 4] (P=0.01), and from aortic declamping until stop of extracorporeal perfusion [phase 5] (P=0.05). Post hoc analysis revealed
that MiECC-F generated a higher HITS rate than CECC+F (P=0.005), CECC-F (P=0.05) in phase 4, and CECC-F (P=0.03) in phase 5, respectively. In open-heart surgery, MiECC is not superior to CECC with regard to gaseous cerebral microembolism. When using MiECC for SAVR, the use of oxygenators with integrated arterial line filter appears highly advisable."

According to the news editors, the research concluded: "Only with this precaution, MiECC confers a cerebral microembolic load comparable to CECC during this type of open heart surgery."

The news correspondents report that additional information may be obtained from G. Erdoes, University of Bern, University Hospital Bern, Dept. of Anesthesiol & Pain Therapy, Inselspital, Bern, Switzerland. Additional authors for this research include F. Kroninger, E. Gygax, H. Jenni, D. Reineke, M. Stucki, N. Hagenbuch, T. Carrel, B. Eberle and G. Erdoes.

Keywords for this news article include: Bern, Switzerland, Europe, Operative Surgical Procedures, Clinical Trials and Studies, Extracorporeal Circulation, Clinical Research, Heart Surgery, Cardiology, University of Bern.

**Oncology - Multiple Myeloma**

**Researchers from University of Bologna Describe Findings in Multiple Myeloma [The genetic and genomic background of multiple myeloma patients achieving complete response after induction therapy with bortezomib, thalidomide and dexamethasone ...]**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Oncology - Multiple Myeloma. According to news reporting originating from Bologna, Italy, by NewsRx correspondents, research stated, "The prime focus of the current therapeutic strategy for Multiple Myeloma (MM) is to obtain an early and deep tumor burden reduction, up to the level of complete response (CR). To date, no description of the characteristics of the plasma cells (PC) prone to achieve CR has been reported."

Our news editors obtained a quote from the research from the University of Bologna, "This study aimed at the molecular characterization of PC obtained at baseline from MM patients in CR after bortezomib-thalidomide-dexamethasone (VTD) first line therapy. One hundred and eighteen MM primary tumours obtained from homogeneously treated patients were profiled both for gene expression and for single nucleotide polymorphism genotype. Genomic results were used to obtain a predictor of sensitivity to VTD induction therapy, as well as to describe both the transcription and the genomic profile of PC derived from MM with subsequent optimal response to primary induction therapy. By analysing the gene profiles of CR patients, we identified a 5-gene signature predicting CR with an overall median accuracy of 75% (range: 72%-85%). In addition, we highlighted the differential expression of a series of genes, whose
deregulation might explain patients' sensitivity to VTD therapy."

According to the news editors, the research concluded: "We also showed that a small copy number loss, covering 606Kb on chromosome 1p22.1 was the most significantly associated with CR patients."

For more information on this research see: The genetic and genomic background of multiple myeloma patients achieving complete response after induction therapy with bortezomib, thalidomide and dexamethasone (VTD). Oncotarget, 2016;7(9):9666-79.

The news editors report that additional information may be obtained by contacting C. Terragna, Seragnoli Institute of Hematology, Dept. of Experimental, Diagnostic and Specialty Medicine (DIMES), Bologna University School of Medicine, Bologna, Italy. Central Nervous System Diseases and Conditions - …

Researchers from University of Bonn Describe Findings in Limbic Encephalitis (Suspected antibody negative autoimmune limbic encephalitis: outcome of immunotherapy)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Central Nervous System Diseases and Conditions - Limbic Encephalitis. According to news reporting originating in Bonn, Germany, by NewsRx journalists, research stated, "Whether and when to immunologically treat epilepsy patients with suggested autoantibody (AB)-negative limbic encephalitis (LE) is clinically challenging. Therefore, we evaluated the clinical outcome and eventual outcome predictors of immunotherapy in a group of AB-negative patients with recent-onset temporal lobe epilepsy (TLE), magnetic resonance imaging (MRI) indicators of LE, subjective cognitive decline, and/or psychiatric symptoms."

The news reporters obtained a quote from the research from the University of Bonn, "This retrospective, observational, uncontrolled study monitored 28 TLE patients with suggested AB-negative LE along with methylprednisolone immunotherapy. All patients had seizures, amygdala and/or - hippocampal enlargement, subjective cognitive decline and/or behavioral problems. Eighty-six percent (24/28) were impaired in executive or memory functions, 39% (10/25) depressed, 81% were on antiepileptic drugs when pulse therapy started. After a median follow-up of 18 months, 46% (13/28) of the patients were seizure free (>2 months), 48% (13/27) showed MRI improvements (amygdala and/or hippocampal volume reduction),
cognition improved in 57% (16/28), worsened in 32% (9/28), mood improved in 14% (4/25), and deteriorated in 11% (3/25). Immunotherapy was discontinued in 75% (21/28). Clinical changes did not correlate to each other. Outcomes could not be predicted. Immunological treatment of suggested AB-negative LE showed reasonable seizure control, MRI and cognitive improvements. Treatment success was not predictable from clinical features, nor definitely attributable to immunological treatment.

According to the news reporters, the research concluded: "Lacking biomarkers for the reliable diagnosis of AB-negative LE, we suggest that in presence of mild manifestations, and after initiating antiepileptic drug therapy, negative dynamics in MRI, seizures, cognition, and behavior should be documented before immunosuppressive treatment is initiated."

Our news correspondents report that additional information may be obtained by contacting C. Helmstaedter, University of Bonn, Dept. of Epileptol, Medical Center, D-53105 Bonn, Germany. Additional authors for this research include J. Wagner, G. Widman, M.P. Malter, C.E. Elger and C. Helmstaedter.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1111/ane.12575. This DOI is a link to an online electronic document that is either free or for purchase.

Oncology - Gliomas

Researchers from University of Bonn Report New Studies and Findings in the Area of Gliomas [Temozolomide chemotherapy versus radiotherapy in high-risk low-grade glioma (EORTC 22033-26033): a randomised, open-label, phase 3 intergroup study]

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Oncology - Gliomas. According to news reporting originating in Bonn, Germany, by NewsRx journalists, research stated, "Background Outcome of low-grade glioma (WHO grade II) is highly variable, reflecting molecular heterogeneity of the disease. We compared two different, single-modality treatment strategies of standard radiotherapy versus primary temozolomide chemotherapy in patients with low-grade glioma, and assessed progression-free survival outcomes and identified predictive molecular factors."
Financial supporters for this research include Canadian Cancer Society Research Institute, National Health and MRC project grant.

The news reporters obtained a quote from the research from the University of Bonn, "For this randomised, open-label, phase 3 intergroup study (EORTC 22033-26033), undertaken in 78 clinical centres in 19 countries, we included patients aged 18 years or older who had a low-grade (WHO grade II) glioma (astrocytoma, oligoastrocytoma, or oligodendroglioma) with at least one high-risk feature (aged >40 years, progressive disease, tumour size >5 cm, tumour crossing the midline, or neurological symptoms), and without known HIV infection, chronic hepatitis B or C virus infection, or any condition that could interfere with oral drug administration. Eligible patients were randomly assigned (1:1) to receive either conformal radiotherapy (up to 50.4 Gy; 28 doses of 1.8 Gy once daily, 5 days per week for up to 6.5 weeks) or dose-dense oral temozolomide (75 mg/m(2) once daily for 21 days, repeated every 28 days [one cycle], for a maximum of 12 cycles). Random treatment allocation was done online by a minimisation technique with prospective stratification by institution, 1p deletion (absent vs present vs undetermined), contrast enhancement (yes vs no), age (<40 vs >= 40 years), and WHO performance status (0 vs >= 1). Treating physicians, and researchers were aware of the assigned intervention. A planned analysis was done after 216 progression events occurred. Our primary clinical endpoint was progression-free survival, analysed by intention-to-treat; secondary outcomes were overall survival, adverse events, neurocognitive function (will be reported separately), health-related quality of life and neurological function (reported separately), and correlative analyses of progression-free survival by molecular markers (1p/19q co-deletion, MGMT promoter methylation status, and IDH1/IDH2 mutations). This trial is closed to accrual but continuing for follow-up, and is registered at the European Trials Registry, EudraCT 2004-002714-11, and at ClinicalTrials.gov, NCT00182819. Between Sept 23, 2005, and March 26, 2010, 707 patients were registered for the study. Between Dec 6, 2005, and Dec 21, 2012, we randomly assigned 477 patients to receive either radiotherapy (n=240) or temozolomide chemotherapy (n=237). At a median follow-up of 48 months (IQR 31-56), median progression-free survival was 39 months (95% CI 35-44) in the temozolomide group and 46 months (40-56) in the radiotherapy group (unadjusted hazard ratio [HR] 1.16, 95% CI 0.9-1.5, p=0.22). Median overall survival has not been reached. Exploratory analyses in 318 molecularly-defined patients confirmed the significantly different prognosis for progression-free survival in the three recently defined molecular low-grade glioma subgroups (IDHmt, with or without 1p/19q co-deletion, IDHmt/codel, or IDH wild type [IDHwt]; p=0.013). Patients with IDHmt/non-codel tumours treated with radiotherapy had a longer progression-free survival than those treated with temozolomide (HR 1.86 [95% CI 1.21-2.87], log-rank p=0.0043), whereas there were no significant treatment-dependent differences in progression-free survival for patients with IDHmt/codel and IDHwt tumours. Grade 3-4 haematological adverse events occurred in 32 (14%) of 236 patients treated with temozolomide and in one (1%) of 228 patients treated with radiotherapy, and grade 3-4 infections occurred in eight (3%) of 236 patients treated with temozolomide and in two (1%) of 228 patients treated with radiotherapy. Moderate to severe fatigue was recorded in eight (3%) patients in the radiotherapy group (grade 2) and 16 (7%) in the temozolomide group. 119 (25%) of all 477 patients had died at database lock. Four patients died due to treatment-related causes: two in the temozolomide group and two in the radiotherapy group. Overall, there was no significant difference in progression-free survival in patients with low-grade glioma when treated with either radiotherapy alone or temozolomide chemotherapy alone."

According to the news reporters, the research concluded: "Further data maturation is needed for overall survival analyses and evaluation of the full predictive effects of different molecular subtypes for future individualised treatment choices."

Proteins - Armadillo Domain Proteins

Researchers from University of Bordeaux Provide Details of New Studies and Findings in the Area of Armadillo Domain Proteins [Fzd7 (Frizzled-7) Expressed by Endothelial Cells Controls Blood Vessel Formation Through Wnt/beta-Catenin Canonical ...]

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Proteins - Armadillo Domain Proteins. According to news reporting originating from Bordeaux, France, by NewsRx correspondents, research stated, "Vessel formation requires precise orchestration of a series of morphometric and molecular events controlled by a multitude of angiogenic factors and morphogens. Wnt/frizzled signaling is required for proper vascular formation."

Our news editors obtained a quote from the research from the University of Bordeaux, "In this study, we investigated the role of the Fzd7 (frizzled-7) receptor in retinal vascular development and its relationship with the Wnt/beta-catenin canonical pathway and Notch signaling. Approach and Results-Using transgenic mice, we demonstrated that Fzd7 is required for postnatal vascular formation. Endothelial cell (EC) deletion of fzd7 (fzd7(ECKO)) delayed retinal plexus formation because of an impairment in tip cell phenotype and a decrease in stalk cell proliferation. Dvl1 (dishevelled) proteins are a main component of Wnt signaling and play a functionally redundant role. We found that Dvl3 depletion in dvl1(-/-) mice mimicked the fzd7(ECKO) vascular phenotype and demonstrated that Fzd7 acted via beta-catenin activation by showing that LiCl treatment rescued impairment in tip and stalk cell phenotypes induced in fzd7 mutants. Deletion of fzd7 or Dvl1/3 induced a strong decrease in Wnt canonical genes and Notch partners' expression. Genetic and pharmacological rescue strategies demonstrated that Fzd7 acted via beta-catenin activation, upstream of Notch signaling to control Dll4 and Jagged1 EC expression."
According to the news editors, the research concluded: "Fzd7 expressed by EC drives postnatal angiogenesis via activation of Dvl/beta-catenin signaling and can control the integrative interaction of Wnt and Notch signaling during postnatal angiogenesis."

For more information on this research see: Fzd7 (Frizzled-7) Expressed by Endothelial Cells Controls Blood Vessel Formation Through Wnt/beta-Catenin Canonical Signaling. *Arteriosclerosis Thrombosis and Vascular Biology*, 2016;36(12):2369-2380. *Arteriosclerosis Thrombosis and Vascular Biology* can be contacted at: Lippincott Williams & Wilkins, Two Commerce Sq, 2001 Market St, Philadelphia, PA 19103, USA.

**Oncology - Cancer Genetics**

**Researchers from University of Bremen Describe Findings in Cancer Genetics (Hyperhaploid uterine mesenchymal tumors-a novel genetic subgroup?)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Oncology - Cancer Genetics is now available. According to news reporting from Bremen, Germany, by NewsRx journalists, research stated, "Hyperhaploid karyotypes have been described to occur in subsets of various solid tumors and leukemias. In these cases, monosomy is noted for most of the chromosomes while a few chromosomes still remain disomic."

The news correspondents obtained a quote from the research from the University of Bremen, "Evidence has emerged that at least in some tumor entities these remaining chromosomes are non-randomly selected. In addition, structural alterations can accompany the reduced chromosome number and secondary duplication of the chromosome complement is also a frequent finding. In this report, we describe hyperhaploidy in a case of an endometrial stromal nodule of a 50 year old woman who underwent hysterectomy because of symptomatic uterine fibroids. In addition, we review two other recently described cases of uterine mesenchymal tumors with that type of genetic alteration. Despite some histologic differences, striking similarities between these three cases exist with respect to the chromosomes were retained as disomic."

According to the news reporters, the research concluded: "Thus, the question arises if hyperhaploidy defines a novel genetic subgroup of uterine mesenchymal tumors."

Researchers from University of Brest Detail Findings in Colon Cancer
(Acquisition of anticancer drug resistance is partially associated with cancer sternness in human colon cancer cells)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Oncology - Colon Cancer have been presented. According to news reporting originating in Brest, France, by NewsRx journalists, research stated, "Colorectal cancer (CRC) is one of the most aggressive cancers worldwide. Several anticancer agents are available to treat CRC, but eventually cancer relapse occurs."

The news reporters obtained a quote from the research from the University of Brest, "One major cause of chemotherapy failure is the emergence of drug-resistant tumor cells, suspected to originate from the stem cell compartment. The aim of this study was to ask whether drug resistance was associated with the acquisition of stem cell-like properties. We isolated drug-resistant derivatives of two human CRC cell lines, HT29 and HCT116, using two anticancer drugs with distinct modes of action, oxaliplatin and docetaxel. HT29 cells resistant to oxaliplatin and both HT29 and HCT116 cells resistant to docetaxel were characterized for their expression of genes potentially involved in drug resistance, cell growth and cell division, and by surveying stem cell-like phenotypic traits, including marker genes, the ability to repair cell-wound and to form colonospheres. Among the genes involved in platinum or taxane resistance (MDR1, ABCG2, MRP2 or ATP7B), MDR1 was uniquely overexpressed in all the resistant cells. An increase in the cyclin-dependent kinase inhibitor p21, in cyclin D1 and in CD26, CD166 cancer stem cell markers, was noted in the resistant cells, together with a higher ability to form larger and more abundant colonospheres. However, many phenotypic traits were selectively altered in either HT29- or in HCT116-resistant cells. Expression of EPHB2, ITG beta-1 or Myc was specifically increased in the HT29-resistant cells, whereas only HCT116-resistant cells efficiently repaired cell-wounds. Taken together, our results show that human CRC cells selected for their resistance to anticancer drugs displayed a few stem cell characteristics, a small fraction of which was shared between cell lines."

According to the news reporters, the research concluded: "The occurrence of marked phenotypic differences between HT29- and HCT116-drug resistant cells indicates that the acquired resistance depends mostly on the parental cell characteristics, rather than on the drug type used."

Our news correspondents report that additional information may be obtained by
Researchers from University of Buckingham Report Details of New Studies and Findings in the Area of Obesity [Circulating Levels of the Adipokines Monocyte Chemotactic Protein-4 (MCP-4), Macrophage Inflammatory Protein-1 beta (MIP-1 beta), and ...]

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Nutritional and Metabolic Diseases and Conditions - Obesity. According to news reporting out of Buckingham, United Kingdom, by NewsRx editors, research stated, "The aim of the study was to investigate the involvement of the adipokines eotaxin-3, MIP-1 beta, and MCP-4 in obesity and related comorbidities and the modification of their circulating levels after bariatric surgery. Eighty severely obese subjects and 20 normal-weight controls were included in the study."

Our news journalists obtained a quote from the research from the University of Buckingham, "Circulating levels of MCP-4, MIP-1 beta, and eotaxin-3, and the main clinical, biochemical, and instrumental parameters for the evaluation of cardiovascular and metabolic profile were determined in controls and in obese subjects at baseline and 10 months after surgery. Within the obese group at baseline, eotaxin-3 levels were higher in males than females and in smokers than non-smokers and showed a positive correlation with LDL-cholesterol, apolipoprotein B, and leptin. MIP-1 beta showed a positive correlation with age and leptin and a negative correlation with adiponectin and was an independent predictor of increased carotid artery intima-media thickness. MCP-4 levels were higher in obese subjects than controls and showed a positive correlation with body mass index, eotaxin-3, and MIP-1 beta. Bariatric surgery induced a marked decrease in all the 3 adipokines. MCP-4 is a novel biomarker of severe obesity and could have an indirect role in favoring sub-clinical atherosclerosis in obese patients by influencing the circulating levels of eotaxin-3 and MIP-1 beta, which are directly related to the main atherosclerosis markers and risk factors."

According to the news editors, the research concluded: "The reduction of circulating levels of MCP-4, eotaxin-3, and MIP-1 beta could be one of the mechanisms by which bariatric surgery contributes to the reduction of cardiovascular risk in these patients."

For more information on this research see: Circulating Levels of the Adipokines Monocyte Chemotactic Protein-4 (MCP-4), Macrophage Inflammatory Protein-1 beta (MIP-1 beta), and Eotaxin-3 in Severe Obesity and Following Bariatric Surgery. Hormone and Metabolic Research, 2016;48(12):847-853. Hormone and Metabolic Research can be contacted at: Georg Thieme Verlag Kg, Rudigerstr 14, D-70469 Stuttgart, Germany. (Thieme - www.thieme.com)

Researchers from University of Cagliari Detail New Studies and Findings in the Area of G-Protein-Coupled Receptors (In vitro and in vivo pharmacological characterization of SSD114, a novel GABAB positive allosteric modulator)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Membrane Proteins - G-Protein-Coupled Receptors have been presented. According to news reporting out of Cagliari, Italy, by NewsRx editors, research stated, "Positive allosteric modulators (PAMs) of the GABA(B) receptor have emerged as a novel approach to the pharmacological manipulation of the GABA(B) receptor, enhancing the effects of receptor agonists with few side effects. Here, we identified N-cyclohexyl-4-methoxy-6-(4 (trifluoromethyl)phenyl)pyrimidin-2-amine (SSD114) as a new compound with activity as a GABA(B) PAM in in vitro and in vivo assays.

Financial supporters for this research include ERAB, Fondazione Banco di Sardegna.

Our news journalists obtained a quote from the research from the University of Cagliari, "SSD114 potentiated GABA-stimulated [S-35]GTP gamma S binding to native GABA (B) receptors, whereas it had no effect when used alone. Its effect on GTP gamma S stimulation was suppressed when GABA-induced activation was blocked with CGP54626, a competitive antagonist of the GABA(B) receptor. SSD114 failed to potentiate WIN55,212,2-, morphine- and quinpirole-induced [S-35]GTP gamma S binding to cortical and striatal membranes, respectively, indicating that it is a selective GABA(B) PAM. Increasing SSD114 fixed concentrations induced a leftward shift of the GABA concentration-response curve, enhancing the potency of GABA rather than its efficacy. SSD114 concentration-response curves in the presence of fixed concentrations of GABA (1,10, and 20 mu M) revealed a potentiating effect on GABA-stimulated binding of [S-35]GTP gamma S to rat cortical membranes, with EC50 values in the low micromolar range. Bioluminescence resonance energy transfer (BRET) experiments in Chinese Hamster Ovary (CHO)-cells expressing GABA(B) receptors showed that SSD114 potentiates the GABA inhibition of adenylyl-cyclase mediated by GABA(B) receptors. Our compound is also effective in vivo potentiating baclofen-induced
sedation/hypnosis in mice, with no effect when tested alone."

According to the news editors, the research concluded: "These findings indicate that SSD114, a molecule with a different chemical structure compared to known GABA(B) PAMs, is a novel GABA(B) PAM with potential usefulness in the GABA(B)-receptor research field."

For more information on this research see: In vitro and in vivo pharmacological characterization of SSD114, a novel GABAB positive allosteric modulator. European Journal of Pharmacology, 2016;791():115-123. European Journal of Pharmacology can be contacted at: Elsevier Science Bv, PO Box 211, 1000 Ae Amsterdam, Netherlands. (Elsevier - www.elsevier.com; European Journal of Pharmacology - www.journals.elsevier.com/european-journal-of-pharmacology/)

Researchers from University of California Describe Findings in Clinical Trials and Studies (Randomised controlled trial evaluation of Tweet2Quit: a social network quit-smoking intervention)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Clinical Research - Clinical Trials and Studies. According to news reporting from Irvine, California, by NewsRx journalists, research stated, "We evaluated a novel Twitter-delivered intervention for smoking cessation, Tweet2Quit, which sends daily, automated communications to small, private, self-help groups to encourage high-quality, online, peer-to-peer discussions. A 2-group randomised controlled trial assessed the net benefit of adding a Tweet2Quit support group to a usual care control condition of nicotine patches and a cessation website."

The news correspondents obtained a quote from the research from the University of California, "Participants were 160 smokers (4 cohorts of 40/cohort), aged 18-59 years, who intended to quit smoking, used Facebook daily, texted weekly, and had mobile phones with unlimited texting. All participants received 56 days of nicotine patches, emails with links to the smokefree.gov cessation website, and instructions to set a quit date within 7 days. Additionally, Tweet2Quit participants were enrolled in 20-person, 100-day Twitter groups, and received daily discussion topics via Twitter, and daily engagement feedback via text. The primary outcome was sustained abstinence at 7, 30 and 60 days post-quit date. Participants (mean age 35.7 years, 26.3% male, 31.2% college degree, 88.7% Caucasian) averaged 18.0 (SD=8.2) cigarettes per day and 16.8 (SD=9.8) years of smoking. Participants randomised to Tweet2Quit averaged 58.8
tweets/participant and the average tweeting duration was 47.4 days/participant. Tweet2Quit doubled sustained abstinence out to 60 days follow-up (40.0%, 26/65) versus control (20.0%, 14/70), OR=2.67, CI 1.19 to 5.99, p=0.017. Tweeting via phone predicted tweet volume, and tweet volume predicted sustained abstinence (p <0.001). The daily autocommunications caused tweeting spikes accounting for 24.0% of tweets. Tweet2Quit was engaging and doubled sustained abstinence."

According to the news reporters, the research concluded: "Its low cost and scalability makes it viable as a global cessation treatment."

For more information on this research see: Randomised controlled trial evaluation of Tweet2Quit: a social network quit-smoking intervention. Tobacco Control, 2016();. (BMJ Publishing Group - group.bmj.com; Tobacco Control - tobaccocontrol.bmj.com/)

Oncology - Breast Cancer

Researchers from University of California Detail Findings in Breast Cancer (Comparing Coordinated Versus Sequential Salpingo-Oophorectomy for BRCA1 and BRCA2 Mutation Carriers With Breast Cancer)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Oncology - Breast Cancer. According to news reporting originating from San Francisco, California, by NewsRx correspondents, research stated, "Women with breast cancer who carry BRCA mutations must also consider risk-reducing salpingo-oophorectomy (RRSO). Sixty-two patients who knew their mutation carrier status before undergoing breast cancer surgery were given the option to undergo combined breast and RRSO surgeries."

Our news editors obtained a quote from the research from the University of California, "Coordinating RRSO with breast surgery is associated with longer operating times and hospital stays without an increase in complications. Women with breast cancer who carry BRCA1 or BRCA2 mutations must also consider risk-reducing salpingo-oophorectomy (RRSO) and how to coordinate this procedure with their breast surgery. We report the factors associated with coordinated versus sequential surgery and compare the outcomes of each. Patients in our cancer risk database who had breast cancer and a known deleterious BRCA1/2 mutation before undergoing breast surgery were included. Women who chose concurrent RRSO at the time of breast surgery were compared to those who did not. Sixty-two patients knew their mutation carrier status before undergoing breast cancer surgery. Forty-three patients (69%) opted for
coordinated surgeries, and 19 (31%) underwent sequential surgeries at a median follow-up of 4.4 years. Women who underwent coordinated surgery were significantly older than those who chose sequential surgery (median age of 45 vs. 39 years; P = .025). There were no differences in comorbidities between groups. Patients who received neoadjuvant chemotherapy were more likely to undergo coordinated surgery (65% vs. 37%; P = .038). Sequential surgery patients had longer hospital stays (4.79 vs. 3.44 days, P = .01) and longer operating times (8.25 vs. 6.38 hours, P = .006) than patients who elected combined surgery. Postoperative complications were minor and were no more likely in either group (odds ratio, 4.76; 95% confidence interval, 0.56-40.6). Coordinating RRSO with breast surgery is associated with receipt of neoadjuvant chemotherapy, longer operating times, and hospital stays without an observed increase in complications."

According to the news editors, the research concluded: "In the absence of risk, surgical options can be personalized."
MDD."

Our news editors obtained a quote from the research from the University of California, "This study investigated the efficacy of ECT on long-term clinical outcome of comorbid PTSD and MDD. This retrospective nested matched case-control study is inclusive of 22,164 subjects [3,485 with comorbid MDD and PTSD (92 with ECT and 3,393 without ECT) and 18,679 without MDD and PTSD]. Using the clinical global impression scale (CGI) to assess efficacy, more-robust improvement of PTSD and MDD symptoms was observed with ECT (90%), compared to antidepressant-treatment alone (50%) (P = 0.001). During the median of 8 years of follow-up, the death-rate was 8% in subjects without PTSD and MDD, 9.7% in PTSD and MDD treated with ECT and 18% in PTSD and MDD without ECT (P < 0.05). The suicide-rate was 2.2 and 5.9% in PTSD and MDD with and without ECT-treatment, respectively (P < 0.05). Survival-analyses revealed that the relative-risk of cardiovascular and all-cause mortality is not significantly different in patients with comorbid MDD and PTSD treated with ECT, compared to a matched-cohort without PTSD and MDD (P > 0.05). The relative risk of suicidality, all-cause, and cardiovascular mortality was reduced 64, 65, and 46% in MDD and PTSD patients treated with ECT, compared to those without ECT (P < 0.05)."

According to the news editors, the research concluded: "ECT is associated with a significant reduction of symptoms of PTSD and MDD, as well as reduction in risk of suicidality, cardiovascular, and all-cause mortality in MDD and PTSD, an effect more robust than antidepressant-therapy alone."

The news editors report that additional information may be obtained by contacting N. Ahmadi, University of California, David Geffen Sch Med, Los Angeles, CA 90095, United States. Additional authors for this research include L. Moss, E. Simon, C.B. Nemeroff and N. Atre-Vaidya.

journalists, research stated, "Hematopoietic stem cells (HSCs) are capable of giving rise to all blood cell lineages throughout adulthood, and the generation of engraftable HSCs from human pluripotent stem cells is a major goal for regenerative medicine. Here, we describe a functional genome-wide RNAi screen to identify genes required for the differentiation of embryonic stem cell (ESC) into hematopoietic stem/progenitor cells (HSPCs) in vitro."

Funders for this research include National Institute of Allergy and Infectious Diseases (NIAID), National Institute on Drug Abuse (NIDA).

The news correspondents obtained a quote from the research from the University of California, "We report the discovery of novel genes important for the endothelial-to-hematopoietic transition and subsequently for HSPC specification. High-throughput sequencing and bioinformatic analyses identified twelve groups of genes, including a set of 351 novel genes required for HSPC specification. As in vivo proof of concept, four of these genes, Ap2a1, Mettl22, Lrsam1, and Hal, are selected for validation, confirmed to be essential for HSPC development in zebrafish and for maintenance of human HSCs."

According to the news reporters, the research concluded: "Taken together, our results not only identify a number of novel regulatory genes and pathways essential for HSPC development but also serve as valuable resource for directed differentiation of therapy grade HSPCs using human pluripotent stem cells."

For more information on this research see: Identification of novel genes and networks governing hematopoietic stem cell development. EMBO Reports, 2016;17(12):1814-1828. EMBO Reports can be contacted at: Wiley-Blackwell, 111 River St, Hoboken 07030-5774, NJ, USA. (Nature Publishing Group - www.nature.com/; EMBO Reports - www.nature.com/embor/)

**Nutritional and Metabolic Diseases and Conditions** …

**Researchers from University of California Report Findings in Type 2 Diabetes (Piperine’s mitigation of obesity and diabetes can be explained by its up-regulation of the metabolic rate of resting muscle)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Nutritional and Metabolic Diseases and Conditions - Type 2 Diabetes is now available. According to news reporting originating in San Francisco, California, by NewsRx journalists, research stated, "We identify a target for treating obesity and
type 2 diabetes, the consumption of calories by an increase in the metabolic rate of resting skeletal muscle. The metabolic rate of skeletal muscle can be increased by shifting myosin heads from the super-relaxed state (SRX), with a low ATPase activity, to a disordered relaxed state (DRX), with a higher ATPase activity."

The news reporters obtained a quote from the research from the University of California, "The shift of myosin heads was detected by a change in fluorescent intensity of a probe attached to the myosin regulatory light chain in skinned skeletal fibers, allowing us to perform a high-throughput screen of 2,128 compounds. The screen identified one compound, which destabilized the super-relaxed state, piperine (the main alkaloid component of black pepper). Destabilization of the SRX by piperine was confirmed by single-nucleotide turnover measurements. The effect was only observed in fast twitch skeletal fibers and not in slow twitch fibers or cardiac tissues. Piperine increased ATPase activity of skinned relaxed fibers by 66 +/- 15%. The K-d was similar to 2 mu M. Piperine had little effect on the mechanics of either fully active or resting muscle fibers. Previous work has shown that piperine can mitigate both obesity and type 2 diabetes in rodent models of these conditions. We propose that the increase in resting muscle metabolism contributes to these positive effects."

According to the news reporters, the research concluded: "The results described here show that up-regulation of resting muscle metabolism could treat obesity and type 2 diabetes and that piperine would provide a useful lead compound for the development of these therapies."

For more information on this research see: Piperine's mitigation of obesity and diabetes can be explained by its up-regulation of the metabolic rate of resting muscle. Proceedings of the National Academy of Sciences of the United States of America. 2016;113 (46):13009-13014. Musculoskeletal Diseases and Conditions - Arthritis

Researchers from University of California Report New Studies and Findings in the Area of Arthritis [Epipolymorphisms associated with the clinical outcome of autoimmune arthritis affect CD4(+) T cell activation pathways]
2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Musculoskeletal Diseases and Conditions - Arthritis. According to news reporting from Los Angeles, California, by NewsRx journalists, research stated, "Multifactorial diseases, including autoimmune juvenile idiopathic arthritis (JIA), result from a complex interplay between genetics and environment. Epigenetic mechanisms are believed to integrate such gene-environment interactions, fine-tuning gene expression, and possibly contributing to immune system dysregulation."

The news correspondents obtained a quote from the research from the University of California, "Although anti-TNF therapy has strongly increased JIA remission rates, it is not curative and up to 80% of patients flare upon treatment withdrawal. Thus, a crucial unmet medical and scientific need is to understand the immunological mechanisms associated with remission or flare to inform clinical decisions. Here, we explored the CD4(+) T-cell DNA methyolome of 68 poly-articular and extended oligo-articular JIA patients, before and after anti-TNF therapy withdrawal, to identify features associated with maintenance of inactive disease. Individual CpG sites were clustered in coherent modules without a priori knowledge of their function through network analysis. The methylation level of several CpG modules, specifically those enriched in CpG sites belonging to genes that mediate T-cell activation, uniquely correlated with clinical activity. Differences in DNA methylation were already detectable at the time of therapy discontinuation, suggesting epigenetic predisposition. RNA profiling also detected differences in T-cell activation markers (including HLA-DR) but, overall, its sensitivity was lower than epigenetic profiling. Changes to the T-cell activation signature at the protein level were detectable by flow cytometry, confirming the biological relevance of the observed alterations in methylation."

According to the news reporters, the research concluded: "Our work proposes epigenetic discrimination between clinical activity states, and reveals T-cell-related biological functions tied to, and possibly predicting or causing, clinical outcome."

Our news journalists report that additional information may be obtained by contacting R. Spreafico, University of California, Inst Quantitat & Computat Biosci, Los Angeles, CA 90095, United States. Additional authors for this research include M. Rossetti, J.W. Whitaker, W. Wang, D.J. Lovell and S. Albani.

Researchers from University of California Report New Studies and Findings in the Area of Chronic Hepatitis C Virus (Impact of gender and menopausal status on metabolic parameters in chronic hepatitis C infection)

Liver Diseases and Conditions - Chronic Hepatitis C

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Liver Diseases and Conditions - Chronic Hepatitis C Virus have been published. According to news originating from San Francisco, California, by NewsRx correspondents, research stated, "Hepatitis C infection (HCV) and menopause are associated with insulin resistance (IR), and IR accelerates HCV-induced liver disease. The relationship between menopause and IR has not been studied in this population."

Funders for this research include NIH/NCATS UCSF-CTSI, UCSF Liver Center.

Our news journalists obtained a quote from the research from the University of California, "This study aimed to assess the impact of menopause on IR and metabolic syndrome in HCV. One hundred and three (69 men, 16 premenopausal, 18 postmenopausal women) noncirrhotic, nondiabetic HCV-infected adults underwent IR measurement via steady-state plasma glucose during a 240-min insulin suppression test. Metabolic syndrome was defined by at least three of five standard laboratory/clinical criteria. The patient characteristics were as follows: mean age 48 years, waist circumference 94.4 ? 12.4 cm and 37.9% Caucasian. SSPG was higher in postmenopausal than premenopausal women or men (mean difference 18, 95% CI -41 to 76 and 35, 95% CI -3 to 72 mg/dL; respectively). After adjusting for waist circumference, female gender, nonwhite race and triglycerides were positively associated and high-density lipoprotein negatively associated with steady-state plasma glucose. Compared to men, both pre-(Coef 48, 95% CI 12-84) and postmenopausal women (Coef 49, 95% CI 17-82) had higher steady-state plasma glucose. Compared to premenopausal women, men (OR 2.0, 95% CI 0.38-10.2) and postmenopausal women (OR 2.9, 95% CI 0.46-18.8) had higher odds of metabolic syndrome, but this was statistically nonsignificant. Both liver inflammation (OR 7.9) and nonwhite race (OR 6.9) were associated with metabolic syndrome. We conclude that women are at increased risk for IR in HCV. There may also be an increased risk of metabolic syndrome postmenopause."

According to the news editors, the research concluded: "Along with lifestyle modification and weight loss, women with metabolic abnormalities represent an especially at-risk group warranting HCV treatment to prevent adverse metabolic outcomes."

The news correspondents report that additional information may be obtained from C.A. Gonzales, Dept. of Medicine, University of California San Francisco, San Francisco, CA, United States. Additional authors for this research include P. Bacchetti and M. Khalili.

Researchers from University of California Report Recent Findings in Child and Adolescent Development (Sexual Risk-Taking Among Recently Emancipated Female Foster Youth: Sexual Trauma and Failed Family Reunification Experiences)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Pediatrics - Child and Adolescent Development. According to news reporting out of Riverside, California, by NewsRx editors, research stated, "Foster youth evidence shows elevated rates of risk behaviors, including sexual risk-taking (e.g., unprotected sex). Some studies have identified child maltreatment, particularly sexual abuse, as a risk for later sexual risk-taking, but none have examined how child welfare placement experiences relate to youth's sexual risk-taking."

Financial support for this research came from William T. Grant Foundation.

Our news journalists obtained a quote from the research from the University of California, "This study investigated relations among child maltreatment, child welfare placements, and sexual risk-taking among 114 recently emancipated female foster youth. Sexual abuse and failed reunifications with parents were associated with greater sexual risk-taking. Moreover, dissociative symptoms exacerbated the relation between sexual abuse and sexual risk-taking."

According to the news editors, the research concluded: "These findings highlight the need for greater consideration of risks associated with emancipated youth's sexual risk-taking and for more research to understand how youth experience unsuccessful family reunifications."

Our news journalists report that additional information may be obtained by contacting A. Gonzalez-Blanks, University of California, Riverside, CA 92507, United States.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1111/jora.12232. This DOI is a link to an online electronic document that is either free or for purchase.

Keywords for this news article include: Riverside, California, United States, North and Central America, Child and Adolescent Development, Pediatrics, Risk and Prevention, University of California.

Researchers from University of California Report Recent Findings in Epithelial Cells (Downregulation of 26S proteasome catalytic activity promotes epithelial-mesenchymal transition)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Epithelial Cells. According to news originating from La Jolla, California, by NewsRx correspondents, research stated, "The epithelial-mesenchymal transition (EMT) endows carcinoma cells with phenotypic plasticity that can facilitate the formation of cancer stem cells (CSCs) and contribute to the metastatic cascade. While there is substantial support for the role of EMT in driving cancer cell dissemination, less is known about the intracellular molecular mechanisms that govern formation of CSCs via EMT."

Our news journalists obtained a quote from the research from the University of California, "Here we show that b2 and b5 proteasome subunit activity is downregulated during EMT in immortalized human mammary epithelial cells. Moreover, selective proteasome inhibition enabled mammary epithelial cells to acquire certain morphologic and functional characteristics reminiscent of cancer stem cells, including CD44 expression, self-renewal, and tumor formation. Transcriptomic analyses suggested that proteasome-inhibited cells share gene expression signatures with cells that have undergone EMT, in part, through modulation of the TGF-β signaling pathway. These findings suggest that selective downregulation of proteasome activity in mammary epithelial cells can initiate the EMT program and acquisition of a cancer stem cell-like phenotype."

According to the news editors, the research concluded: "As proteasome inhibitors become increasingly used in cancer treatment, our findings highlight a potential risk of these therapeutic strategies and suggest a possible mechanism by which carcinoma cells may escape from proteasome inhibitor-based therapy."

For more information on this research see: Downregulation of 26S proteasome catalytic activity promotes epithelial-mesenchymal transition. Oncotarget, 2016;7(16):21527-41.

The news correspondents report that additional information may be obtained from A. Banno, Dept. of Medicine, University of California San Diego, La Jolla, CA, United States. Researchers from University of California Report on Findings in Hypertension (White matter disease in midlife is heritable, related to hypertension, and shares some genetic influence with systolic blood pressure)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Cardiovascular Diseases and Conditions - Hypertension are discussed in a new report. According to news reporting originating in La Jolla, California, by NewsRx journalists, research stated, "White matter disease in the brain increases with age and cardiovascular disease, emerging in midlife, and these associations may be influenced by both genetic and environmental factors. We examined the frequency, distribution, and heritability of abnormal white matter and its association with hypertension in 395 middle-aged male twins (61.9 +/- 2.6 years) from the Vietnam Era Twin Study of Aging, 67% of whom were hypertensive."

Financial supporters for this research include National Institute on Aging, National Institute on Alcohol Abuse and Alcoholism.

The news reporters obtained a quote from the research from the University of California, "A multi-channel segmentation approach estimated abnormal regions within the white matter. Using multivariable regression models, we characterized the frequency distribution of abnormal white matter in midlife and investigated associations with hypertension and Apolipoprotein E-epsilon 4 status and the impact of duration and control of hypertension. Then, using the classical twin design, we estimated abnormal white matter heritability and the extent of shared genetic overlap with blood pressure. Abnormal white matter was predominantly located in periventricular and deep parietal and frontal regions; associated with age (t = 1.9, p = 0.05) and hypertension (t= 2.9, p = 0.004), but not Apolipoprotein epsilon 4 status; and was greater in those with uncontrolled hypertension relative to controlled (t= 3.0, p= 0.003) and normotensive (t = 4.0, p= 0.0001) groups, suggesting that abnormal white matter may reflect currently active cerebrovascular effects. Abnormal white matter was highly heritable (a(2) = 0.81) and shared some genetic influences with systolic blood pressure (r(A) = 0.26), although there was evidence for distinct genetic contributions and unique environmental influences."

According to the news reporters, the research concluded: "Future longitudinal research will shed light on factors impacting white matter disease presentation, progression, and potential recovery."

For more information on this research see: White matter disease in midlife is heritable, related to hypertension, and shares some genetic influence with systolic blood pressure. Neuroimage-Clinical, 2016;12():737-745. Neuroimage-Clinical can be contacted at: Elsevier Sci Ltd, The Boulevard, Langford Lane, Kidlington, Oxford OX5 1GB, Oxon, England.

Our news correspondents report that additional information may be obtained by contacting C. Fennema-Notestine, University of California, Dept. of Radiol, La Jolla, CA 92093, United States. Additional authors for this research include L.K. McEvoy, R. Notestine, M.S. Panizzon, W.Y.W. Yau, C.E. Franz, M.J. Lyons, L.T. Eyler, M.C. Neale, H. Xian, R.E. McKenzie and W.S. Kremen.

Researchers from University of Camerino Discuss Findings in Pharmacology (Pharmacological Effects of Capparis spinosa L)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Pharmacology have been published. According to news originating from Camerino, Italy, by NewsRx correspondents, research stated, "Medicinal plants have been known as one of the most important therapeutic agents since ancient times. During the last two decades, much attention has been paid to the health-promoting effects of edible medicinal plants, because of multiple beneficial effects and negligible adverse effects. Capparis spinosa L. is one of the most common medicinal plants, used widely in different parts of the world to treat numerous human diseases."

Our news journalists obtained a quote from the research from the University of Camerino, "This paper aims to critically review the available scientific literature regarding the health-promoting effects of C. spinosa, its traditional uses, cultivation protocols and phytochemical constituents. Recently, a wide range of evidence has shown that this plant possesses different biological effects, including antioxidant, anticancer and antibacterial effects. Phytochemical analysis shows that C. spinosa has high quantities of bioactive constituents, including polyphenolic compounds, which are responsible for its health-promoting effects, although many of these substances are present in low concentrations and significant changes in their content occur during processing. In addition, there is negligible scientific evidence regarding any adverse effects. Different health promotion activities, as well as tremendous diversity of active constituents, make C. spinosa a good candidate for discovering new drugs."

According to the news editors, the research concluded: "However these findings are still in its infancy and future experimental and clinical studies are needed."

The news correspondents report that additional information may be obtained from F. Maggi, University of Camerino, Sch Pharm, I-62032 Camerino, Italy. Additional authors for this research include F. Maggi, M. Daglia, S. Habtemariam, L. Rastrelli and S.M. Nabavi.

Keywords for this news article include: Camerino, Italy, Europe, Therapy, Article Review, Pharmacology, University of Camerino.

Researchers from University of Catania Detail Findings in Multiple Sclerosis (Risk factors in multiple sclerosis: a population-based case-control study in Sicily. Background and methods)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Autoimmune Diseases and Conditions - Multiple Sclerosis have been published. According to news reporting from Catania, Italy, by NewsRx journalists, research stated, "Incidence of multiple sclerosis (MS) has steeply increased over time during the last 30 years in the city of Catania. We carried out a population-based case-control study to evaluate the possible role of both environmental and genetic factors."

The news correspondents obtained a quote from the research from the University of Catania, "From 1975 to 2004 in Catania, 367 MS patients diagnosed according to the Poser's criteria had the onset of disease. A sample of MS patients was randomly selected from this incident cohort. Three controls matched by age and sex were randomly selected from the rosters of 14 GPs. Controls were proportionally selected according to the distribution by municipality of the target population using a multistage sampling methods. All cases and controls underwent a face-to-face interview to record information concerning environmental factors and a blood sample was taken for serological and genetic analysis. 164 MS patients (64 % women; mean age of 46.4 +/- 10.7) and 481 controls (69 % women; mean age of 47.7 +/- 14.8) were enrolled in the study. The distribution of the whole population and the selected controls by municipalities was similar. A blood sample was taken from 150 MS cases and from 337 controls. At the end of the enrolment, we obtained a representative sample of the MS cases and population controls avoiding possible selection bias."

According to the news reporters, the research concluded: "Participation rate was very high also concerning the collection of biological specimens."

For more information on this research see: Risk factors in multiple sclerosis: a population-based case-control study in Sicily. Background and methods. Neurological Sciences, 2016;37(12):1931-1937. Researchers from University of Catania Report Details of New Studies and Findings in the Area of Essential Tremor (Pregabalin for essential tremor)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Musculoskeletal Diseases and Conditions - Essential Tremor have been published. According to news reporting out of Catania, Italy, by NewsRx editors, research stated, "Essential tremor is one of the most common movement disorders. Treatment primarily consists of pharmacological agents."

Our news journalists obtained a quote from the research from the University of Catania, "While primidone and propranolol are well-established treatments in clinical practice, they may be ineffective in 25% to 55% of patients and can produce serious adverse events in a large percentage of them. For these reasons, it is worth evaluating the treatment alternatives for essential tremor. Some specialists have suggested that pregabalin could be a potentially useful agent, but there is uncertainty about its efficacy and safety. To assess the effects of pregabalin versus placebo or other treatment for essential tremor in adults. Search methods We performed a systematic search without language restrictions to identify all relevant trials up to December 2015. We searched the Cochrane Central Register of Controlled Trials (CENTRAL), MEDLINE, Embase, NICE, ClinicalTrials.gov, and the World Health Organization International Clinical Trials Registry Platform (ICTRP). We handsearched grey literature and examined the reference lists of identified studies and reviews. Selection criteria We included all randomised controlled trials (RCTs) of pregabalin versus placebo or any other treatments. We included studies in which the diagnosis of ET was made according to accepted and validated diagnostic criteria. We excluded studies conducted in patients presenting secondary forms of tremor or reporting only neurophysiological parameters to assess outcomes. Data collection and analysis Two reviewers independently collected and extracted data using a data collection form. We assessed the risk of bias of the body of evidence, and we used inverse variance methods to analyse continuous outcomes and measurement scales. We compared the mean difference between treatment groups, and we combined results for dichotomous outcomes using Mantel-Haenszel methods and risk differences We used Review Manager software for data management and analysis. We only found one study eligible for this review (22 participants). We assessed the risk of bias for most domains as unclear. We graded the overall quality of evidence as very low. Compared to placebo, patients treated with pregabalin showed no significant improvement of motor tasks on the 36-point subscale of the Fahn-Tolosa-Marin Tremor Rating Scale (TRS) (MD -2.15 points; 95% CI -9.16 to 4.86) or on the 32-point functional abilities subscale of the TRS (MD -0.66 points; 95% CI -2.90 to 1.58). The limited evidence showed no difference in study withdrawal (Mantel-Haenszel RD -0.09; 95% CI -0.48 to 0.30) and presentation of adverse events between pregabalin and placebo (Mantel-Haenszel RD 0.18; 95% CI -0.13 to 0.50). Authors' conclusions The effects of pregabalin for treating essential tremor are uncertain because the quality of the evidence is very low."

According to the news editors, the research concluded: "One small study did not highlight any effect of this treatment; however, the high risk of bias and the lack of other studies on this topic limit further conclusion."

For more information on this research see: Pregabalin for essential tremor. Cochrane Database of Systematic Reviews, 2016;(10):135-160. Cochrane Database of Systematic Reviews can be contacted at: Wiley-Blackwell, 111 River St, Hoboken 07030-5774,
Researchers from University of Catania Report Recent Findings in Liver Diseases (Intracellular and extracellular miRNome deregulation in cellular models of NAFLD or NASH: Clinical implications)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Liver Diseases have been presented. According to news reporting originating from Catania, Italy, by NewsRx correspondents, research stated, "Nonalcoholic fatty liver disease (NAFLD) represents the most common chronic liver disease in industrialized countries. NAFLD has the potential to progress through the inflammatory phase of nonalcoholic steatohepatitis (NASH) to fibrosis, cirrhosis, and hepatocellular carcinoma."

Our news editors obtained a quote from the research from the University of Catania, "Identifying patients at risk for this transition is a relevant clinical challenge. The complexity of these phenotypes in vivo made necessary the development of in vitro models in order to dissect the molecular signalling affected in NAFLD and NASH, but also to identify potential circulating biomarkers. We profiled the expression of 754 cellular and medium-secreted human miRNAs in HepG2 cells after lipotoxic (Palmitate, model of NASH) or not-lipotoxic stimuli (Oleate-Palmitate, model of NAFLD). Results were validated through Single TaqMan assays. We performed computational analysis of miRNA targets and pathways. Oleate-palmitate treatment induced a variation of 2.8% and 10% of total miRNAs in cells and medium, respectively; palmitate treatment caused 10% and 19% intracellular and extracellular miRNA deregulation, respectively. We validated miR-126, miR-150, miR-223, miR-483-3p, miR-1226*, and miR-1290 deregulation. Through computational analysis, we observed that targets of both intracellular and extracellular DE miRNAs were involved in processes associated with the onset and progression of NAFLD and NASH, such as fatty acid metabolism, apoptosis and inflammation."

According to the news editors, the research concluded: "These data would be useful to elucidate the role of miRNAs in the pathogenesis and progression of the NAFLD spectrum, but they also allow the identification of novel potential biomarkers for differential diagnosis to be tested in vivo."

For more information on this research see: Intracellular and extracellular miRNome deregulation in cellular models of NAFLD or NASH: Clinical implications. *Nutrition Metabolism and Cardiovascular Diseases*, 2016;26(12):1129-1139. *Nutrition Metabolism and
Researchers from University of Chicago Detail New Studies and Findings in the Area of Oncology Nursing (Interdisciplinary Pain Education: Moving From Discipline-Specific to Collaborative Practice)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Nursing - Oncology Nursing. According to news reporting originating in Chicago, Illinois, by NewsRx journalists, research stated, "Pain is a common symptom reported by hospitalized patients with cancer. Cancer pain management requires an interdisciplinary approach for quality patient care."

The news reporters obtained a quote from the research from the University of Chicago, "Although the literature suggests that most cancer pain can be managed with available treatments, many patients continue to experience pain even with opioid prescriptions. Implementation of evidence-based guidelines, such as the National Comprehensive Cancer Network's guidelines for adult cancer pain, promotes collaboration across disciplines and enhances patient care. This article reports the development, implementation, and evaluation of an interdisciplinary pain education program, Oncology Provider Pain Training (OPPT), to improve clinician knowledge and promote collaborative practice. The Kirkpatrick Model was used to design the OPPT program. A multifaceted training approach was used to accommodate the various needs of potential participants. Interdisciplinary educational sessions were held during a one-month period. Knowledge gained, learner reaction, and satisfaction were evaluated using predetermined benchmarks one month following program completion. Satisfaction benchmarks for content, teaching materials, and presenter were met. Although the knowledge gained benchmark was not met, substantial progress toward achievement was made. Additional modifications include increasing discipline-specific content and focus on pain pathophysiology and addressing time constraints."

According to the news reporters, the research concluded: "Inconsistent technology adoption across disciplines may have a negative effect on interdisciplinary educational efforts."

For more information on this research see: Interdisciplinary Pain Education: Moving From Discipline-Specific to Collaborative Practice. *Clinical Journal of Oncology Nursing,*
Researchers from University of Chicago Report Recent Findings in Obesity (The Gut Microbiota The Gateway to Improved Metabolism)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Nutritional and Metabolic Diseases and Conditions - Obesity is now available. According to news reporting out of Chicago, Illinois, by NewsRx editors, research stated, "Obesity is an emerging global epidemic with profound challenges to world health care economies and societies."

Our news journalists obtained a quote from the research from the University of Chicago, "Traditional approaches to fighting obesity have not shown promise in promoting a decline in obesity prevalence. The gut microbiota is becoming widely appreciated for its role in regulating metabolism and thus represents a target for new therapies to combat obesity and associated comorbidities."

According to the news editors, the research concluded: "This article provides an overview of altered microbial community structure in obesity, dietary impact on the gut microbiota, host-microbe interactions contributing to the disease, and improvements in microbial assemblage after bariatric surgery and with therapies targeting the gut microbiome."

Our news journalists report that additional information may be obtained by contacting E.B. Chang, University Chicago, Dept. of Med, Knapp Center Biomed Discovery, Sect Gastroenterol Hepatol & Nutr, Chicago, IL 60637, United States. Additional authors for this research include J.F. Pierre and E.B. Chang.

Researchers from University of Chile Describe Findings in Nanocarriers (Potential use of nanocarriers with pentacyclic triterpenes in cancer treatments)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Nanotechnology - Nanocarriers are presented in a new report. According to news reporting out of Santiago, Chile, by NewsRx editors, research stated, "Ursolic, oleanolic and betulinic acids are representative pentacyclic triterpenoids found in various plants and fruits."

Our news journalists obtained a quote from the research from the University of Chile, "Despite having marked antitumor potentials, the very poor water solubility of these triterpenes hinders treatment development. Nanotechnology can enhance solubility, stability, bioavailability and phytochemical delivery, improving the therapeutic efficiency of triterpenes."

According to the news editors, the research concluded: "This review focuses on the formulation, characterization and in vitro/in vivo evaluation of several delivery nanosystems used to enhance the physicochemical properties of ursolic, oleanolic and betulinic acids."

Our news journalists report that additional information may be obtained by contacting K. Valdes, University of Chile, Fac Ciencias Quim & Farmaceut, Dept. of Ciencias & Tecnol Farmaceut, Santiago, Chile. Additional authors for this research include J. Morales, L. Rodriguez and G. Gunther.

Researchers from University of Colorado Report Findings in Fatty Liver

Liver Diseases and Conditions - Fatty Liver

Sevelamer Improves Steatohepatitis, Inhibits Liver and Intestinal Farnesoid X Receptor (FXR), and Reverses Innate Immune Dysregulation in a Mouse Model of Non-alcoholic ...]
lower blood glucose and increase insulin sensitivity by altering bile acid signaling pathways."

Financial supporters for this research include U.S. Department of Veterans Affairs, National Institutes of Health.

Our news journalists obtained a quote from the research from the University of Colorado, "In this study, we assessed the efficacy of sevelamer in treating mice with non-alcoholic fatty liver disease (NAFLD). We also analyzed how sevelamer alters inflammation and bile acid signaling in NAFLD livers. Mice were fed a low-fat or Western diet for 12 weeks followed by a diet-plus-sevelamer regimen for 2 or 12 weeks. At the end of treatment, disease severity was assessed, hepatic leukocyte populations were examined, and expression of genes involved in farnesoid X receptor (FXR) signaling in the liver and intestine was analyzed. Sevelamer treatment significantly reduced liver steatosis and lobular inflammation. Sevelamer-treated NAFLD livers had notably fewer pro-inflammatory infiltrating macrophages and a significantly greater fraction of alternatively activated Kupffer cells compared with controls. Expression of genes involved in FXR signaling in the liver and intestine was significantly altered in mice with NAFLD as well as in those treated with sevelamer. In a mouse model of NAFLD, sevelamer improved disease and counteracted innate immune cell dysregulation in the liver."

According to the news editors, the research concluded: "This study also revealed a dysregulation of FXR signaling in the liver and intestine of NAFLD mice that was counteracted by sevelamer treatment."

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Drugs and Therapies - Angiotensin Converting Enzyme Inhibitors are discussed in a new report. According to news reporting originating in Concepcion, Chile, by NewsRx journalists, research stated, "Rapid stability-indicating LC methods for simultaneous analysis of quinapril and hydrochlorothiazide were developed, validated and compared using evaporative light scattering detection (ELSD) and diode array detection (DAD). For the separation of quinapril, hydrochlorothiazide and its major degradation products, a monolithic column was used and the analytes were eluted within 7 min, applying gradient mobile phase in both methods."

Financial support for this research came from FONDECYT.

The news reporters obtained a quote from the research from the University of Concepcion, "Quinapril was subjected to hydrolytic, oxidative, thermal, humidity and photolytic stress conditions. Degradation products were well resolved from main peaks and from each other, proving the stability-indicating power of the methods. The response with DAD was linear and the response with ELSD was fitted to a power function, for quinapril and hydrochlorothiazide concentrations of 20-160 and 12.5-100 µg mL(-1), respectively. DAD method achieved better precision than ELSD method, the LOQ of DAD was lower and the accuracy of the methods was similar. Quinapril degrade by hydrolysis and thermal stress, showing the formation of quinaprilat and quinapril diketopiperazine as degradants, which were identified by MS-MS. The methods were successfully applied to quantify quinapril and hydrochlorothiazide in commercial tablets."

According to the news reporters, the research concluded: "LC-DAD and LC-ELSD methods are suitable to assess the stability and routine analysis of quinapril and hydrochlorothiazide in pharmaceutical industry."

Our news correspondents report that additional information may be obtained by contacting M. de Diego, Univ Concepcion, Fac Pharm, Concepcion, Chile. Additional authors for this research include R. Godoy, S. Mennickent, C. Vergara, H. Charnock and C. Hernandez.

Oncology - Breast Cancer

Researchers from University of Connecticut Report Details of New Studies and Findings in the Area of Breast Cancer (Relationships among psychoneurological symptoms and levels of C-reactive protein over 2 years in women with early-stage breast ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Oncology - Breast Cancer are discussed in a new report. According to news reporting out of Storrs, Connecticut, by NewsRx editors, research stated, "The aim of the present study was to explore clusters of psychoneurological symptoms and inflammation (levels of C-reactive protein) over time in a cohort of women with early-stage breast cancer. Specifically, we examined the relationships among affective symptoms (depression, anxiety, fatigue, sleep disturbances, pain, and perceived stress), domains of cognitive performance, and levels of peripheral C-reactive over a period of 2 years."

Our news journalists obtained a quote from the research from the University of Connecticut, "This was a prospective, longitudinal study of 77 women diagnosed with early-stage breast cancer. Data collection, including symptom questionnaires, performance-based cognitive testing, and blood draws, took place at 5 time points: prior to initiating adjuvant chemotherapy, prior to the fourth chemotherapy treatment, and at 6, 12, and 24 months after the initiation of chemotherapy. Exploratory factor analysis with varimax orthogonal rotation was used to examine the covariance among symptoms at each visit. Using the factor scores and weighted sums, three clusters were identified: global cognition, affective symptoms, and cognitive efficiency. Peripheral levels of C-reactive protein were inversely correlated with the cognitive efficiency factor across time. The findings suggest that objectively measured domains of cognitive function occur independently of other affective symptoms that are commonly reported by women with breast cancer in long-term survivorship."

According to the news editors, the research concluded: "The cognitive efficiency symptom cluster may be amenable to interventions targeted to biological influences that reduce levels of C-reactive protein."

For more information on this research see: Relationships among psychoneurological symptoms and levels of C-reactive protein over 2 years in women with early-stage breast cancer. Researchers from University of Copenhagen Detail Findings in Heart Failure (Clinical and prognostic correlates of pulmonary congestion in coronary computed tomography angiography data sets)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Heart Disorders and Diseases - Heart Failure are discussed in a new report. According to news reporting originating from Copenhagen, Denmark, by NewsRx correspondents, research stated, "Signs of pulmonary congestion obtained from cardiac computed tomography angiographic (coronary CTA) images have not previously been related to clinical congestion or outcome and the clinical value is, therefore, unknown. Our objective was to test the hypothesis that signs of pulmonary congestion predict clinical heart failure and adverse outcome in patients with myocardial infarction."

Funders for this research include The Danish Council for Strategic Research, Research Fund of Rigshospitalet, A.P Moller and Chastine McKinney Moller Foundation.

Our news editors obtained a quote from the research from the University of Copenhagen, "Coronary CTA was performed before invasive treatment in 400 prospectively included patients with non ST segment elevation myocardial infarction in an observational study. Using a previously described chest computed tomography evaluation algorithm, patients were classified as having 'no congestion', 'mild to moderate congestion' or 'severe congestion'. Using multivariate analyses, presence of pulmonary congestion on coronary CTA images was associated with age, female gender, left ventricular ejection fraction (LVEF) and left atrial size. The diagnostic accuracy for predicting clinical heart failure, defined as Killip class >1 was: sensitivity: 83%, specificity: 69%, positive predictive value: 25%, and negative predictive value: 97%. The median follow-up time was 50 months and the study end-point of death or hospitalization due to heart failure was reached in 68 (16%) patients. In a Cox proportional hazards model with adjustments for known risk factors and Killip class, the presence of 'mild to moderate congestion' and 'severe congestion' was independently associated with adverse outcome (Hazard ratio: 2.6 (95% CI:1.3-5.0) and 3.2 (1.3-7.5))."

According to the news editors, the research concluded: "Signs of pulmonary congestion on coronary CTA images are closely correlated to cardiac dysfunction, predict clinical heart failure, and provide prognostic value independent of LVEF and Killip class."

The news reporters that additional information may be obtained by contacting J.T. Kuhl, University of Copenhagen, Rigshospitalet, Center Heart, Dept. of Cardiol, DK-1168 Copenhagen, Denmark. Additional authors for this research include T.S. Kristensen, A.F. Thomsen, L. Hindso, K.L. Hansen, O.W. Nielsen, H. Kelbaek and K.E. Kofoed.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1016/j.jcct.2016.09.002. This DOI is a link to an online electronic document that is either free or for purchase.
Researchers from University of Copenhagen Report Findings in Acute Coronary Syndrome (Depression following acute coronary syndrome: a Danish nationwide study of potential risk factors)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Heart Disorders and Diseases - Acute Coronary Syndrome is the subject of a report. According to news reporting originating from Copenhagen, Denmark, by NewsRx correspondents, research stated, "Depression is common following acute coronary syndrome, and thus, it is important to provide knowledge to improve prevention and detection of depression in this patient group. The objectives of this study were to examine: (1) whether indicators of stressors and coping resources were risk factors for developing depression early and later after an acute coronary syndrome and (2) whether prior depression modified these associations."

Funders for this research include The Danish Tryg foundation, The Danish Heart Association.

Our news editors obtained a quote from the research from the University of Copenhagen, "The study was a register-based cohort study, which includes 87,118 patients with a first time diagnosis of acute coronary syndrome during the period 2001-2009 in Denmark. Cox regression models were used to analyse hazard ratios (HRs) for depression. 1.5 and 9.5 % develop early (currency sign30 days) and later (31 days-2 years) depression after the acute coronary syndrome. Among all patients with depression, 69.2 % had first onset depression, while 30.8 % developed a recurrent depression. Most patient characteristics (demographic factors, socioeconomic status, psychosocial factors, health-related behavioural factors, somatic comorbidities, and severity of acute coronary syndrome) were significantly associated with increased HRs for both early and later depressions. Prior depression modified most of these associations in such a way that the association was attenuated in patients with a prior depression. Our results indicate that first time and recurrent depression following acute coronary syndrome have different risk profiles."

According to the news editors, the research concluded: "This is important knowledge that may be used to focus future interventions for prevention and detection."

For more information on this research see: Depression following acute coronary syndrome: a Danish nationwide study of potential risk factors. Social Psychiatry and Psychiatric Epidemiology, 2016;51(11):1509-1523. Social Psychiatry and Psychiatric Epidemiology can be contacted at: Springer Heidelberg, Tiergartenstrasse 17, D-69121 Heidelberg, Germany. Researchers from University of Copenhagen Report on Findings in Anxiolitics Sedatives and Hypnotics (Buccal absorption of diazepam is improved when administered in bioadhesive tablets-An in vivo study in conscious Gottingen mini-pigs)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Drugs and Therapies - Anxiolitics Sedatives and Hypnotics are discussed in a new report. According to news reporting out of Copenhagen, Denmark, by NewsRx editors, research stated, "Buccal delivery may be clinically beneficial for compounds with a high gastrointestinal and hepatic first pass metabolism or in situations where a fast systemic absorption is desired. The delivery of a crystalline low soluble compounds, e.g. diazepam, may be limited due to the low volume of saliva available to facilitate solvation in order to drive the permeation of drug through the buccal mucosa."

Our news journalists obtained a quote from the research from the University of Copenhagen, "Therefore, the present study investigated the potential benefits of administering diazepam either as an amorphous or as a crystalline form in mucoadhesive tablets to conscious Gottingen mini-pigs. Presentation of the compound in the amorphous form lead to a very fast absorption, however, the obtained bioavailability was at the same level observed following buccal administration of a commercially immediate release tablet. Addition of chitosan, as a mucoadhesive excipient, resulted in a higher absolute bioavailability compared to tablets without chitosan. The absorption rate for the chitosan-based tablets was significant slower, probably due to the slower diffusion of the compound out of the tablet."

According to the news editors, the research concluded: "In vitro release data was able to predict the variations in t(max), but otherwise no correlation could be found between in vitro and in vivo data."

Our news journalists report that additional information may be obtained by contacting J. Jacobsen, University of Copenhagen, Fac Hlth & Med Sci, Dept. of Pharm, DK-2100 Copenhagen, Denmark. Additional authors for this research include J. Jacobsen, A. Mullertz, E.B. Jorgensen and R. Holm.

Keywords for this news article include: Copenhagen, Denmark, Europe, Anxiolytics Sedatives and Hypnotics, Benzodiazepine Anticonvulsants, Central Nervous System Agents, Drugs and Therapies, Benzodiazepines, Diazepam, University of Copenhagen.

Oncology - Breast Cancer

Researchers from University of Crete Report New Studies and Findings in the Area of Breast Cancer (IGF-I/EGF and E2 signaling crosstalk through IGF-IR conduit point affects breast cancer cell adhesion)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Oncology - Breast Cancer are presented in a new report. According to news originating from Iraklion, Greece, by NewsRx correspondents, research stated, "Epidermal growth factor (EGF)/insulin like growth factor-I (IGF-I) and Estradiol (E2) can regulate biological functions of hormone-dependent tumor cells. Fibronectin (FN) is a large glycoprotein abundantly expressed in breast cancer extracellular matrices (ECMs) postulated to be a marker of aggressiveness during cancer pathogenesis."

Financial supporters for this research include European Social Fund, Greek National Funds.

Our news journalists obtained a quote from the research from the University of Crete, "In this study we demonstrate that IGF-I/EGF as well E2 strongly increase the adhesion of the MCF-7 breast cancer cells onto FN. Moreover, IGF-IR is necessary for the IGF-I-/EGF- and E2-induced cell adhesion. Erk1/2 inhibition abolished the IGF-I-/EGF-/E2-induced MCF-7 cell adhesion, suggesting that this regulation of cell adhesion is perpetrated through Erk1/2 downstream signaling. Erk1/2 signaling was shown to modulate IGF-IR status as its inhibition attenuates both IGF-IR expression and activation. Notably, EGF and E2 enhanced the mRNA as well as protein expression of IGF-IR in MCF-7 cells. Confocal microscopy demonstrated that treatment of MCF-7 cells with IGF-I or EGF induced actin reorganization, which was attenuated with Erk1/2 inhibition. Interestingly, IGF-I treatment induced a co-localization of IGF-IR and FAK, which was evident mostly at the cell membranes of MCF-7 cells."

According to the news editors, the research concluded: "In summary, IGF-IR was shown to be a convergence point for the IGF-/EGF- and E2-dependent MCF-7 cell adhesion onto FN."

For more information on this research see: IGF-I/EGF and E2 signaling crosstalk through IGF-IR conduit point affects breast cancer cell adhesion. Matrix Biology, 2016;56():95-113. Matrix Biology can be contacted at: Elsevier Science Bv, PO Box 211, 1000 Ae Amsterdam, Netherlands. (Elsevier - www.elsevier.com; Matrix Biology - www.journals.elsevier.com/matrix-biology/)

The news correspondents report that additional information may be obtained from G.N. Tzanakakis, University of Crete, Sch Med, Lab Anat Histol Embryol, Iraklion, Greece. Additional authors for this research include D. Nikitovic, A. Berdiaki, D. Kletsas, N.K.
Researchers from University of Exeter Detail Findings in Attention Deficit Hyperactivity Disorders (End-user involvement in a systematic review of quantitative and qualitative research of non-pharmacological interventions for attention deficit ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Developmental Diseases and Conditions - Attention Deficit Hyperactivity Disorders have been published. According to news reporting out of Exeter, United Kingdom, by NewsRx editors, research stated, "The benefits of end-user involvement in health-care research are widely recognized by research agencies. There are few published evaluations of end-user involvement in systematic reviews."

Financial supporters for this research include National Institute for Health Research, Exeter NHS Foundation Trust.

Our news journalists obtained a quote from the research from the University of Exeter, "Objectives (i) Describe end-user involvement in a complex mixed-methods systematic review of ADHD in schools, (ii) reflect on the impact of end-user involvement, (iii) highlight challenges and benefits experienced and (iv) provide suggestions to inform future involvement. End-users were involved in all stages of the project, both as authors and as members of an advisory group. In addition, several events were held with groups of relevant end-users during the project. End-user input (i) guided the direction of the research, (ii) contributed to a typology of interventions and outcomes, (iii) contributed to the direction of data analysis and (iv) contributed to the robustness of the syntheses by demonstrating the alignment of interim findings with lived experiences. Challenges included (i) managing expectations, (ii) managing the intensity of emotion, (iii) ensuring that involvement was fruitful for all not just the researcher, (iv) our capacity to communicate and manage the process and (v) engendering a sense of involvement amongst end-users. End-user involvement was an important aspect of this project."

According to the news editors, the research concluded: "To minimize challenges in future projects, a recognition by the project management team and the funding provider that end-user involvement even in evidence synthesis projects is resource intensive is essential to allow appropriate allocation of time and resources for meaningful engagement."

For more information on this research see: End-user involvement in a systematic review of quantitative and qualitative research of non-pharmacological interventions for attention deficit hyperactivity disorder delivered in school settings: reflections on the impacts and challenges. Health Expectations, 2016;19(5):1084-1097. Health Expectations can be contacted at: Wiley-Blackwell, 111 River St, Hoboken 07030-5774, NJ, USA. (Wiley-
Researchers from University of G. d'Annunzio Detail Findings in Cardiovascular Research [Lp(a) and cardiovascular risk: Investigating the hidden side of the moon]

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Cardiovascular Research are discussed in a new report. According to news originating from Chieti, Italy, by NewsRx correspondents, research stated, "This article reports current evidence on the association between Lp(a) and cardiovascular (CV) disease and on pathophysiological mechanisms. The available information on therapy for reduction of lipoprotein(a) is also discussed."

Our news journalists obtained a quote from the research from the University of G. d'Annunzio, "Data synthesis: Although some evidence is conflicting, Lp(a) seems to increase CV risk through stimulation of platelet aggregation, inhibition of tissue factor pathway inhibitor, alteration of fibrin clot structure and promotion of endothelial dysfunction and phospholipid oxidation. Lp(a) 3.5-fold higher than normal increases the risk of coronary heart disease and general CV events, particularly in those with LDL cholesterol >= 130 mg/dl. High Lp(a) values represent also an independent risk factor for ischemic stroke (more relevant in young stroke patients), peripheral artery disease (PAD) and aortic and mitral stenosis. Furthermore, high Lp(a) levels seem to be associated with increased risk of cardiovascular events in patients with chronic kidney disease, particularly in those undergoing percutaneous coronary intervention. Lipoprotein (a) (Lp[a]) seems to significantly influence the risk of cardiovascular events. The effects of statins and fibrates on Lp(a) are limited and extremely variable. Nicotinic acid was shown effective in reducing Lp(a) but, due to its side effects and serious adverse events during clinical trials, it is no longer considered a possible option for treatment. To date, the treatment of choice for high levels of Lp(a) in high CV risk patients is represented by LDL-Apheresis."

According to the news editors, the research concluded: "Thanks to innovative technologies, new selectively inhibiting LPA drugs are being developed and tested."

For more information on this research see: Lp(a) and cardiovascular risk: Investigating the hidden side of the moon. Nutrition Metabolism and Cardiovascular Diseases,
Researchers from University of Geneva Detail New Studies and Findings in the Area of Ischemia (NADPH oxidase 4 deficiency increases tubular cell death during acute ischemic reperfusion injury)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Ischemia. According to news reporting originating from Geneva, Switzerland, by NewsRx correspondents, research stated, "NADPH oxidase 4 (NOX4) is highly expressed in kidney proximal tubular cells. NOX4 constitutively produces hydrogen peroxide, which may regulate important pro-survival pathways."

Our news editors obtained a quote from the research from the University of Geneva, "Renal ischemia reperfusion injury (IRI) is a classical model mimicking human ischemic acute tubular necrosis. We hypothesized that NOX4 plays a protective role in kidney IRI. In wild type (WT) animals subjected to IRI, NOX4 protein expression increased after 24 hours. NOX4 KO (knock-out) and WT littermates mice were subjected to IRI. NOX4 KO mice displayed decreased renal function and more severe tubular apoptosis, decreased Bcl-2 expression and higher histologic damage scores compared to WT. Activation of NRF2 was decreased in NOX4 KO mice in response to IRI. This was related to decreased KEAP1 oxidation leading to decreased NRF2 stabilization. This resulted in decreased glutathione levels. In vitro silencing of NOX4 in cells showed an enhanced propensity to apoptosis, with reduced expression of NRF2, glutathione content and Bcl-2 expression, similar to cells derived from NOX4 KO mice."

According to the news editors, the research concluded: "Overexpression of a constitutively active form of NRF2 (caNRF2) in NOX4 depleted cells rescued most of this phenotype in cultured cells, implying that NRF2 regulation by ROS issued from NOX4 may play an important role in its anti-apoptotic property."

For more information on this research see: NADPH oxidase 4 deficiency increases tubular cell death during acute ischemic reperfusion injury. Scientific Reports, 2016;6():1-14. Scientific Reports can be contacted at: Nature Publishing Group, Macmillan Building, 4 Crinan St, London N1 9XW, England. Researchers from University of Gothenburg Describe Findings in Staphylococcus aureus [Being Met as marked - patients' experiences of being infected with community-acquired methicillin-resistant Staphylococcus aureus (MRSA)]

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Gram-Positive Bacteria - Staphylococcus aureus have been presented. According to news reporting out of Gothenburg, Sweden, by NewsRx editors, research stated, "It is known that patients who acquired methicillin-resistant Staphylococcus aureus (MRSA) in hospitals suffer and feel as plague. Moreover, the patient interaction with nurses and physicians is described as frightening."

Our news journalists obtained a quote from the research from the University of Gothenburg, "Little is known about patient experiences after having acquired CA-MRSA concerning care and everyday life. To reveal and interpret otherwise healthy patients' lived experiences of receiving care and their everyday life after having acquired community MRSA (CA-MRSA). A phenomenological hermeneutic approach guided by Ricouer was conducted. Interviews with twelve patients were transcribed verbatim into a text. The text was analysed in three phases: naive understanding, structural analysis and comprehensive understanding to reveal a possible being in the world. In this study, this referred to what it means to be infected with CA-MRSA. The findings indicate that patients who acquired MRSA experience a changed body image. They suffer from ignorant and frightened behavior from healthcare workers, social contacts, and also of being bullied by colleagues. Despite this, patients assume great responsibility for protecting others. However, knowledgeable staff alleviate suffering and bring peace of mind to the patients. Preventing patient's feelings of being a pest, an outsider living with fear, requires urgent education and understanding about resistant bacteria and how to meet an infected patient."

According to the news editors, the research concluded: "The results describing patients, affected with MRSA, may contribute and touch the readers to better understanding of patient's changed body image and suffering and how to mitigate these feelings."

Our news journalists report that additional information may be obtained by contacting E. Skyman, University of Gothenburg, Dept. of Infect Dis, Inst Biomed, Infect Control Unit, Gothenburg, Sweden. Additional authors for this research include B. Lindahl, I. Bergbom, H.T. Sjostrom and C. Ahren.

Cardiovascular Diseases and Conditions - Thrombosis

Researchers from University of Heidelberg Provide Details of New Studies and Findings in the Area of Thrombosis (Frequency and temporal profile of recanalization after cerebral vein and sinus thrombosis)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Cardiovascular Diseases and Conditions - Thrombosis. According to news reporting originating from Heidelberg, Germany, by NewsRx correspondents, research stated, "The temporal course of recanalization and its association with clinical outcome were analysed in our patients with cerebral sinus and/or venous thrombosis (CSVT) and follow-up magnetic resonance imaging (MRI). Between January 1998 and September 2014 all patients from our institutions with CSVT were systematically analysed."

Our news editors obtained a quote from the research from the University of Heidelberg, "Baseline data, treatment characteristics and follow-up MRI were retrospectively recorded. The status of recanalization was assessed as complete (CRec), partial (PRec) or failed recanalization. Clinical follow-up was measured with the modified Rankin Scale. Excellent outcome was defined as modified Rankin Scale 0-1. Ninety-nine patients were identified; 97% of these patients were treated with oral anticoagulation (OAC) and the median (min-max) time of OAC was 7 months (1-84). CRec was achieved in 57.6% (57/99), PRec in 29.3% (29/99) and only 13 (13.1%) patients did not recanalize. The median (min-max) time to PRec was 4 months (0.25-14) and to CRec 6 months (2-34). Median time to last clinical follow-up was 8 months (1-88); 91.8% (89/99) had an excellent outcome at last clinical follow-up and only 2.1% (2/99) died. Only thrombosis of the superior sagittal sinus was independently associated with successful recanalization (odds ratio 16, 95% confidence interval 2-138). No severe haemorrhagic complications and no recurrence of CSVT occurred within clinical follow-up. No association of outcome and recanalization status was found. The recanalization rate of CSVT under OAC was high and the median time to CRec was 6 months. Thrombosis of the superior sagittal sinus is a positive predictor of recanalization."

According to the news editors, the research concluded: "Outcome in this cohort was excellent but no significant association of outcome and recanalization status was found."

The news editors report that additional information may be obtained by contacting C. Herweh, Dept. of Neuroradiology, University of Heidelberg, Heidelberg, Germany. Additional authors for this research include M. Griebe, C. Geisbusch, K. Szabo, E. Neumaier-Probst, M.G. Hennerici, M. Bendszus, P.A. Ringleb and S. Nagel.

**Heart Disorders and Diseases - Heart Failure**

**Researchers from University of Helsinki Central Hospital Discuss Findings in Heart Failure (Contemporary management of acute right ventricular failure: a statement from the Heart Failure Association and the Working Group on Pulmonary ...)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Heart Disorders and Diseases - Heart Failure. According to news reporting originating in Helsinki, Finland, by NewsRx journalists, research stated, "Acute right ventricular (RV) failure is a complex clinical syndrome that results from many causes. Research efforts have disproportionately focused on the failing left ventricle, but recently the need has been recognized to achieve a more comprehensive understanding of RV anatomy, physiology, and pathophysiology, and of management approaches."

The news reporters obtained a quote from the research from the University of Helsinki Central Hospital, "Right ventricular mechanics and function are altered in the setting of either pressure overload or volume overload. Failure may also result from a primary reduction of myocardial contractility owing to ischaemia, cardiomyopathy, or arrhythmia. Dysfunction leads to impaired RV filling and increased right atrial pressures. As dysfunction progresses to overt RV failure, the RV chamber becomes more spherical and tricuspid regurgitation is aggravated, a cascade leading to increasing venous congestion. Ventricular interdependence results in impaired left ventricular filling, a decrease in left ventricular stroke volume, and ultimately low cardiac output and cardiogenic shock. Identification and treatment of the underlying cause of RV failure, such as acute pulmonary embolism, acute respiratory distress syndrome, acute decompensation of chronic pulmonary hypertension, RV infarction, or arrhythmia, is the primary management strategy. Judicious fluid management, use of inotropes and vasopressors, assist devices, and a strategy focusing on RV protection for mechanical ventilation if required all play a role in the clinical care of these patients."

According to the news reporters, the research concluded: "Future research should aim to address the remaining areas of uncertainty which result from the complexity of RV haemodynamics and lack of conclusive evidence regarding RV-specific treatment approaches."

Our news correspondents report that additional information may be obtained by contacting V.P. Harjola, Emergency Medicine, Helsinki University, Dept. of Emergency Medicine and Services, Helsinki University Hospital, Helsinki, Finland. Additional authors for this research include A. Mebazaa, J. Celutkiene, D. Bettex, H. Bueno, O. Chioncel, M.G. Crespo-Leiro, V. Falk, G. Filippatos, S. Gibbs, A. Leite-Moreira, J. Lassus, J. Masip, C. Mueller, W. Mullens, R. Naeije, A.V. Nordegraaf and Pari.

Central Nervous System Diseases and Conditions …

Researchers from University of Helsinki Report Details of New Studies and Findings in the Area of Brain Injuries (Peroxisome proliferator-activated receptor-g coactivator-1a mediates neuroprotection against excitotoxic brain injury in ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Central Nervous System Diseases and Conditions - Brain Injuries. According to news reporting originating from Helsinki, Finland, by NewsRx correspondents, research stated, "Peroxisome proliferator-activated receptor gamma coactivator-1a (PGC-1a) is a transcriptional coactivator involved in the regulation of mitochondrial biogenesis and cell defense. The functions of PGC-1a in physiology of brain mitochondria are, however, not fully understood."

Funders for this research include Suomen Akatemia, Sigrid Juselius, Liv och Halsa, Finska Lakaresallskapet, Svenska Kulturfonden, Magnus Ehrnroothin Saatio, Parkinson Foundation Finland, Minerva Foundation and Progetti di Ateneo, Universita degli Studi di Palermo.

Our news editors obtained a quote from the research from the University of Helsinki, "To address this we have studied wild-type and transgenic mice with a two-fold overexpression of PGC-1a in brain neurons. Data showed that the relative number and basal respiration of brain mitochondria were increased in PGC-1a transgenic mice compared with wild-type mitochondria. These changes occurred concomitantly with altered levels of proteins involved in oxidative phosphorylation (OXPHOS) as studied by proteomic analyses and immunoblottings. Cultured hippocampal neurons from PGC-1a transgenic mice were more resistant to cell degeneration induced by the glutamate receptor agonist kainic acid. In vivo kainic acid induced
excitotoxic cell death in the hippocampus at 48 h in wild-type mice but significantly less so in PGC-1α transgenic mice. However, at later time points cell degeneration was also evident in the transgenic mouse hippocampus, indicating that PGC-1α overexpression can induce a delay in cell death. Immunoblotting showed that X-linked inhibitor of apoptosis protein (XIAP) was increased in PGC-1α transgenic hippocampus with no significant changes in Bcl-2 or Bcl-X.

According to the news editors, the research concluded: "Collectively, these results show that PGC-1α overexpression contributes to enhanced neuronal viability by stimulating mitochondria number and respiration and increasing levels of OXPHOS proteins and the anti-apoptotic protein XIAP."

The news editors report that additional information may be obtained by contacting J. Makela, Medicum, Dept. of Biochemistry and Developmental Biology, Medical Faculty, University of Helsinki, P.O.B. 63, 00014, Haartmaninkatu 8, FIN-00290, Helsinki, Finland. Additional authors for this research include G. Mudo, D.D. Pham, V. Di Liberto, O. Eriksson, L. Louhivuori, C. Bruelle, R. Soliymani, M. Baumann, L. Korhonen, M. Lalowski, N. Belluardo and D. Lindholm.

**Thrombolysis**

**Researchers from University of Helsinki Report Findings in Thrombolysis (Cutting the Prehospital On-Scene Time of Stroke Thrombolysis in Helsinki A Prospective Interventional Study)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Thrombolysis. According to news originating from Helsinki, Finland, by NewsRx correspondents, research stated, "Significant portion of the prehospital delay consists of minutes spent on the scene with the patient. We implemented a training program for the emergency medical services personnel with the aim to optimize the on-scene time (OST) and to study the impact of different elements of prehospital practice to the OST duration."

Our news journalists obtained a quote from the research from the University of Helsinki, "In this prospective interventional study, key operational emergency medical service performance variables were analyzed from all thrombolysis candidates transported to the Helsinki University Hospital emergency department. The catchment period was 4 months before
and 4 months after the implementation. One hundred and forty-one patients were managed as thrombolysis candidates before and 148 patients after the training program implementation. The OST duration for the groups was 25 (20.5-31) and 22.5 (18-28.5) minutes, respectively (P < 0.001). Physicist consultations via telephone were associated with a longer (odds ratio 0.546 [0.333-0.893]) and advanced life support training with a shorter OST (odds ratio 1.760 [1.070-2.895]). Implementation of the emergency medical services training program successfully decreased the OST of thrombolysis candidates by 10%.

According to the news editors, the research concluded: "Higher expertise level of the ambulance crew was associated with shorter OST, and decisions to consult a physician via telephone were reflected by longer OST."

For more information on this research see: Cutting the Prehospital On-Scene Time of Stroke Thrombolysis in Helsinki A Prospective Interventional Study. *Stroke*, 2016;47 (12):3038-3040. *Stroke* can be contacted at: Lippincott Williams & Wilkins, Two Commerce Sq, 2001 Market St, Philadelphia, PA 19103, USA. (Lippincott Williams and Wilkins - www.lww.com; Stroke - stroke.ahajournals.org/)

The news correspondents report that additional information may be obtained from T. Puolakka, University of Helsinki, Helsinki Univ Hosp, Emergency Med Serv, Helsinki 00099, Finland. Additional authors for this research include M. Kuisma, S. Lankimaki, J. Puolakka, J. Hallikainen, K. Rantanen and P.J. Lindsberg.

Heart Disorders and Diseases - Myocarditis

Researchers from University of Helsinki Report on Findings in Myocarditis (Long-term outcome and its predictors in giant cell myocarditis)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Heart Disorders and Diseases - Myocarditis. According to news reporting originating from Helsinki, Finland, by NewsRx correspondents, research stated, "There are no studies focusing on prognostic factors in giant cell myocarditis (GCM). We aimed to identify predictors of transplant-free survival in GCM."

Our news editors obtained a quote from the research from the University of Helsinki, "We analysed the details of 46 patients with GCM (31 women, mean age 51 +/-12 years) seen at our hospital since 1991 and followed for the occurrence of cardiac death or transplantation till May 2015. The association of transplant-free survival with patient characteristics, laboratory data on admission, and myocardial histology in the 38 patients diagnosed prior to death or transplantation was examined. Altogether 26 patients died (n = 8) or underwent transplantation (n = 18) a median of 11 months following symptom onset. The 5-year estimate of transplant-free survival was 42% [95% confidence interval (CI) 35-48%]. By Cox regression analysis, the hazard ratio for death or transplantation was 0.87 (95% CI 0.75-0.99) per +5% difference in LVEF, 1.06 (95% CI 1.03-1.10) per+ 1000 ng/L difference in NT-proBNP, and 4.57 (95% CI 1.63-11.28) for cardiac troponin-T above the median of 85 ng/L at presentation. The severity of necrosis and fibrosis in myocardial biopsy, graded by the consensus of two cardiac pathologists..."
as none, mild, moderate, or severe, predicted the outcome with a hazard ratio of 7.17 (95% CI 2.29-22.40) for the presence of either necrosis or fibrosis of at least moderate extent. In GCM, the probability of transplant-free survival is 42% at 5 years from symptom onset."

According to the news editors, the research concluded: "Markers of myocyte injury and cardiac dysfunction help predict the outcome."

The news editors report that additional information may be obtained by contacting K. Ekstrom, University of Helsinki, Cent Hosp, Heart & Lung Center, Helsinki 00029, Finland. Additional authors for this research include J. Lehtonen, R. Kandolin, A. Raisanen-Sokolowski, K. Salmenkivi and M. Kupari.

Keywords for this news article include: Helsinki, Finland, Europe, Heart Disorders and Diseases, Giant Cell Myocarditis, Cardiomyopathies, Cardiovascular, Heart Disease, Giant Cells, Cardiology, University of Helsinki.

Cardiovascular Diseases

Researchers from University of Hong Kong Report Recent Findings in Cardiovascular Diseases (The smoke-free legislation in Hong Kong: its impact on mortality)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Cardiovascular Diseases have been published. According to news reporting out of Hong Kong, People's Republic of China, by NewsRx editors, research stated, "To examine trends in deaths for conditions associated with secondhand smoke exposure over the years prior to and following the implementation of a smoke-free policy in Hong Kong. Time-series study. Death registration data from Hong Kong Special Administrative Region (SAR) Government Census and Statistics Department."

Our news journalists obtained a quote from the research from the University of Hong Kong, "All deaths registered from 1 January 2001 to 31 December 2011. Deaths for conditions associated with passive smoking include cardiovascular disease (CVD), respiratory disease and other causes. There was a decline in the annual proportional change for ischaemic heart disease (IHD), acute myocardial infarction (AMI) and CVD mortality in the year after the intervention for all ages and those aged 65 years or older. There were also clear declines in the cool season peaks for these three conditions in the first postintervention year. There was a further drop in the cool season peak for AMI among all ages in the year after the exemptions ceased. No declines in annual proportional change or changes in seasonal peaks of mortality were found for any of the control conditions. The findings in this study add to the evidence base, as summarised in the Surgeon General's report, extending the impact of effective smoke-free legislation to those aged 65 years or older and to cerebrovascular events in younger age groups."

According to the news editors, the research concluded: "They also reinforced the need for comprehensive, enforced and effective smoke-free laws if the full extent of the health
gains are to be achieved."

Our news journalists report that additional information may be obtained by contacting T.Q. Thach, University of Hong Kong, Sch Public Hlth, Pokfulam 852, Hong Kong, People's Republic of China. Additional authors for this research include S.M. McGhee, J.C. So, J. Chau, E.K.P. Chan, C.M. Wong and A.J. Hedley.

**Cell Research - Cell Adhesion Molecules**

**Researchers from University of Illinois Provide Details of New Studies and Findings in the Area of Cell Adhesion Molecules (MicroRNA Regulation of Endothelial Junction Proteins and Clinical Consequence)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Cell Research - Cell Adhesion Molecules. According to news reporting from Chicago, Illinois, by NewsRx journalists, research stated, "Cellular junctions play a critical role in structural connection and signal communication between cells in various tissues. Although there are structural and functional varieties, cellular junctions include tight junctions, adherens junctions, focal adhesion junctions, and tissue specific junctions such as PECAM-1 junctions in endothelial cells (EC), desmosomes in epithelial cells, and hemidesmosomes in EC."

Financial support for this research came from National Natural Science Foundation of China.

The news correspondents obtained a quote from the research from the University of Illinois, "Cellular junction dysfunction and deterioration are indicative of clinical diseases. MicroRNAs (miRNA) are similar to 20 nucleotide, noncoding RNAs that play an important role in posttranscriptional regulation for almost all genes. Unsurprisingly, miRNAs regulate junction protein gene expression and control junction structure integrity. In contrast, abnormal miRNA regulation of junction protein gene expression results in abnormal junction structure, causing related diseases. The major components of tight junctions include zonula occluden-1 (ZO-1), claudin-1, claudin-5, and occludin. The miRNA regulation of ZO-1 has been intensively investigated. ZO-1 and other tight junction proteins such as claudin-5 and occludin were positively regulated by miR-126, miR-107, and miR21 in different models. In contrast, ZO-1, claudin-5, and occludin were negatively regulated by miR-181a, miR-98, and miR150. Abnormal tight junction miRNA regulation accompanies cerebral middle artery ischemia, brain trauma, glioma metastasis, and so forth. The major components of adherens junctions include..."
VE-cadherin, beta-catenin, plakoglobin, P120, and vinculin. VE-cadherin and beta-catenin were regulated by miR-9, miR-99b, miR-181a, and so forth. These regulations directly affect VE-cadherin-beta-catenin complex stability and further affect embryo and tumor angiogenesis, vascular development, and so forth. miR-155 and miR-126 have been shown to regulate PECAM-1 and affect neutrophil rolling and EC junction integrity. In focal adhesion junctions, the major components are integrin beta 4, paxillin, and focal adhesion kinase (FAK). Integrin beta 4 has been regulated by miR-184, miR-205, and miR-9. Paxillin has been regulated by miR-137, miR-145, and miR-218 in different models. FAK has been regulated by miR-7, miR-138, and miR-135. Deregulation of miRNAs is caused by viral infections, tumorigenesis, and so forth. By regulation of posttranscription, miRNAs manipulate junction protein expression in all cellular processes and further determine cellular fate and development.

According to the news reporters, the research concluded: "Elucidation of these regulatory mechanisms will become a new alternative therapy for many diseases, such as cancers and inflammatory diseases."

For more information on this research see: MicroRNA Regulation of Endothelial Junction Proteins and Clinical Consequence. *Meditators of Inflammation*, 2016;():1-6. *Meditators of Inflammation* can be contacted at: Hindawi Publishing Corp, 315 Madison Ave 3RD Flr, Ste 3070, New York, NY 10017, USA. (Hindawi Publishing - www.hindawi.com; Mediators of Inflammation - www.hindawi.com/journals/mi/)

Our news journalists report that additional information may be obtained by contacting W.G. Chen, University of Illinois, Coll Med, Dept. of Med, Div Pulm Crit Care Sleep & Allergy, Chicago, IL 60607, United States. Additional authors for this research include H. Peng, V. Mastej and W.G. Chen.

Oncology - Colon Cancer

Researchers from University of Kansas Report Recent Findings in Colon Cancer (RNA Binding Protein RBM3 Increases beta-Catenin Signaling to Increase Stem Cell Characteristics in Colorectal Cancer Cells)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Oncology - Colon Cancer have been presented. According to news reporting out of Kansas City, Kansas, by NewsRx editors, research stated, "Colorectal cancer (CRC) is the second leading cause of cancer deaths in the United States. It arises from loss of intestinal epithelial homeostasis and hyperproliferation of the crypt epithelium."

Our news journalists obtained a quote from the research from the University of
Kansas, "In order to further understand the pathogenesis of CRC it is important to further understand the factors regulating intestinal epithelial proliferation and more specifically, regulation of the intestinal epithelial stem cell compartment. Here, we investigated the role of the RNA binding protein RBM3 in stem cell homeostasis in colorectal cancers. Using a doxycycline (Dox) inducible RBM3 overexpressing cell lines HCT 116 and DLD-1, we measured changes in side population (SP) cells that have high xenobiotic efflux capacity and increased capacity for self-renewal. In both cell lines, RBM3 induction showed significant increases in the percentage of side population cells. Additionally, we observed increases in spheroid formation and in cells expressing DCLK1, LGR5 and CD44(Hi). As the Wnt/beta-catenin signaling pathway is important for both physiologic and cancer stem cells, we next investigated the effects of RBM3 overexpression on beta-catenin activity. RBM3 overexpression increased levels of nuclear beta-catenin as well as TCF/LEF transcriptional activity. In addition, there was inactivation of GSK3 beta leading to decreased beta-catenin phosphorylation. Pharmacologic inhibition of GSK3 beta using (20Z, 30E)-6-Bromoindirubin-30-oxime (BIO) also recapitulates the RBM3 induced beta-catenin activity."

According to the news editors, the research concluded: "We see that RNA binding protein RBM3 induces stemness in colorectal cancer cells through a mechanism involving suppression of GSK3 beta activity thereby enhancing beta-catenin signaling."

Our news journalists report that additional information may be obtained by contacting S. Anant, University of Kansas, Medical Center, Dept. of Mol & Integrat Physiol, Kansas City, KS 66103, United States. Additional authors for this research include D. Subramaniam, J. Balmaceda, B. Roy, D.A. Dixon, S. Umar, S.J. Weir and S. Anant.

**Oncology - Multiple Myeloma**

**Researchers from University of Kuopio Hospital Detail New Studies and Findings in the Area of Multiple Myeloma (A randomized phase II study of stem cell mobilization with cyclophosphamide+G-CSF or G-CSF alone after lenalidomide-based induction ...)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Oncology - Multiple Myeloma are presented in a new report. According to news reporting originating from Kuopio, Finland, by NewsRx correspondents, research stated, "The most common means of mobilizing autologous stem cells is G-CSF alone
or combined with cyclophosphamide (CY) to obtain sufficient CD34+ cells for one to two transplants. There are few prospective, randomized studies investigating mobilization regimens in multiple myeloma (MM), especially after lenalidomide-based induction."

Our news editors obtained a quote from the research from the University of Kuopio Hospital, "We designed this prospective, randomized study to compare low-dose CY 2 g/m2 +G-CSF (arm A) and G-CSF alone (arm B) after lenalidomide-based up-front induction in MM. Of the 80 initially randomized patients, 69 patients were evaluable, 34 and 35 patients in arms A and B, respectively. The primary end point was the proportion of patients achieving a yield of $\geq 3 \times 10^6$/kg CD34+ cells with 1-2 aphereses, which was achieved in 94% and 77% in arms A and B, respectively (p=0.084). The median number of aphereses needed to reach the yield of $\geq 3 \times 10^6$/kg was lower in arm A than in arm B (1 vs. 2, p=0.035). Two patients needed plerixafor in arm A and five patients in arm B (p=0.428)."

According to the news editors, the research concluded: "Although CY-based mobilization was more effective, G-CSF alone was successful in a great majority of patients to reach the defined collection target after three cycles of lenalidomide-based induction."

For more information on this research see: A randomized phase II study of stem cell mobilization with cyclophosphamide+G-CSF or G-CSF alone after lenalidomide-based induction in multiple myeloma. Bone Marrow Transplantation, 2015;51(3):372-6. Bone Marrow Transplantation can be contacted at: Nature Publishing Group, 345 Park Avenue South, New York, NY 10010-1707, USA. (Nature Publishing Group - www.nature.com/; Bone Marrow Transplantation - www.nature.com/bmt/)

The news editors report that additional information may be obtained by contacting R. Silvennoinen, Dept. of Medicine, Kuopio University Hospital, Kuopio, Finland. Cardiovascular Diseases and Conditions - Hypotension

Researchers from University of KwaZulu-Natal Detail New Studies and Findings in the Area of Hypotension (Recipes for obstetric spinal hypotension: The clinical context counts)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Cardiovascular Diseases and Conditions - Hypotension is
the subject of a report. According to news reporting from Durban, South Africa, by NewsRx journalists, research stated, "Hypotension following obstetric spinal anesthesia remains a common and important problem. While recent research advances have brought us closer to the perfect recipe for the obstetric spinal anesthesia, these advances have not been translated into practical guidelines able to reduce the unacceptable number of fatalities that occur in environments where resources are limited."

The news correspondents obtained a quote from the research from the University of KwaZulu-Natal, "In South Africa, more than half of anaesthetic deaths are still related to spinal hypotension. A gap exists between the 'perfect recipe', developed from a clinical context rooted in resource-rich research environments, and its application and performance in real-world resource-poor environments - conditions experienced by more than 75% of the world's population."

According to the news reporters, the research concluded: "This review attempts to define this knowledge gap and proposes a research agenda to address the deficiencies."

For more information on this research see: Recipes for obstetric spinal hypotension: The clinical context counts. *SAMJ South African Medical Journal*, 2016;106(9):37-40. *SAMJ South African Medical Journal* can be contacted at: Sa Medical Assoc, Block F Castle Walk Corporate Park, Nossob Street, Erasmuskloof EXT3, Pretoria, 0002, South Africa.

Our news journalists report that additional information may be obtained by contacting D.G. Bishop, University of KwaZulu Natal, Nelson R Mandela Sch Med, Sch Clin Med, Coll Hlth Sci, Durban, South Africa. Additional authors for this research include R.N. Rodseth and R.A. Dyer.

**Heart Disorders and Diseases - Heart Failure**

**Researchers from University of Leicester Detail New Studies and Findings in the Area of Heart Failure (Plasma growth hormone is a strong predictor of risk at 1 year in acute heart failure)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Heart Disorders and Diseases - Heart Failure. According to news reporting from Leicester, United Kingdom, by NewsRx journalists, research stated, "We sought to compare the prognostic utility of growth hormone (GH) with NT-proBNP) and the ADHERE score in a large cohort of acute heart failure (HF) patients, subcategorized into HF with reduced EF <50% (HFrEF) and preserved EF (≥)50% (HFpEF). GH and NTproBNP levels were measured in 537 patients (HFrEF n=415; HFpEF n=122) with acute HF recruited into this prospective cohort study."

Financial supporters for this research include John and Lucille Van Geest Foundation, National Institute for Health Research Leicester Cardiovascular Biomedical Research Unit.

The news correspondents obtained a quote from the research from the University of Leicester, "The main outcome measure was death or HF readmission at 1 year. GH levels were higher in both HFrEF [1.26 (0.54-2.62) vs. 0.8 (0.26-1.94) ng/mL, p<0.001] and HFpEF [1.04
(0.48-2.92) vs. 0.53 (0.18-1.94) ng/mL, p=0.020] patients with the outcome compared with event-free survivors. GH levels were independently predictive for the outcome at 1 year in the entire cohort [HR 1.47, 95% confidence interval (CI) 1.16-1.86, p=0.001] and those with HFrEF (HR 1.54, 95% CI 1.19-1.99, p=0.001) in multivariate Cox hazard analysis. GH improved risk classification as measured by continuous net reclassification improvement (NRI) when added to the ADHERE multivariate logistic model of age, sex, urea, heart rate, and systolic blood pressure, for all patients [NRI 29.6 (12.1-47.1), p=0.001] and HFrEF NRI 21.7 (1.9-41.6), p=0.034] patients, as well as in addition to the ADHERE model combined with NT-proBNP for all patients [NRI 25.4 (7.8-43.1), p=0.005]."

According to the news reporters, the research concluded: "GH offers incremental prognostic information over the ADHERE score clinical predictors and NT-proBNP for risk stratification of acute HF patients."

Our news journalists report that additional information may be obtained by contacting S.S. Bhandari, Dept. of Cardiovascular Sciences, University of Leicester, Leicester, UK. Additional authors for this research include H. Narayan, D.J. Jones, T. Suzuki, J. Struck, A. Bergmann, I.B. Squire and L.L Ng.

Researchers from University of Liege Provide Details of New Studies and Findings in the Area of Type 1 Diabetes Mellitus (Practical aspects of gene regulatory inference via conditional inference forests from expression data)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Nutritional and Metabolic Diseases and Conditions - Type 1 Diabetes Mellitus. According to news reporting from Sart Tilman Par Liege, Belgium, by NewsRx journalists, research stated, "Gene regulatory network (GRN) inference is an active area of research that facilitates understanding the complex interplays between biological molecules. We propose a novel framework to create such GRNs, based on Conditional Inference Forests (CIFs) as proposed by Strobl et al."

The news correspondents obtained a quote from the research from the University of Liege, "Our framework consists of using ensembles of Conditional Inference Trees (CITs) and selecting an appropriate aggregation scheme for variant selection prior to network construction. We show on synthetic microarray data that taking the original implementation of CIFs with
conditional permutation scheme (CIFcond) may lead to improved performance compared to Breiman's implementation of Random Forests (RF). Among all newly introduced CIF-based methods and five network scenarios obtained from the DREAM4 challenge, CIFcond performed best. Networks derived from well-tuned CIFs, obtained by simply averaging P-values over tree ensembles (CIFmean) are particularly attractive, because they combine adequate performance with computational efficiency. Moreover, thresholds for variable selection are based on significance levels for P-values and, hence, do not need to be tuned. From a practical point of view, our extensive simulations show the potential advantages of CIFmean-based methods. Although more work is needed to improve on speed, especially when fully exploiting the advantages of CITs in the context of heterogeneous and correlated data, we have shown that CIF methodology can be flexibly inserted in a framework to infer biological interactions.

According to the news reporters, the research concluded: "Notably, we confirmed biologically relevant interaction between IL2RA and FOXP1, linked to the IL-2 signaling pathway and to type 1 diabetes."

Our news journalists report that additional information may be obtained by contacting K. Bessonov, University of Liege, Medical Genom, GIGA R, B-4000 Sart Tilman Par Liege, Belgium.

**Peptide Proteins - Posterior Pituitary Hormones**

**Researchers from University of Liverpool Detail New Studies and Findings in the Area of Posterior Pituitary Hormones (The combination tocolytic effect of magnesium sulfate and an oxytocin receptor antagonist in myometrium from singleton and ...)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Peptide Proteins - Posterior Pituitary Hormones have been published. According to news originating from Liverpool, United Kingdom, by NewsRx correspondents, research stated, "Preterm birth at < 37 weeks of gestation is the most common and costly complication of pregnancy and remains the leading cause of neonatal morbidity, death, and reduced achievement in surviving infants. Magnesium sulfate is 1 class of tocolytics for threatened preterm labor; however, its clinical efficacy has been questioned."

Our news journalists obtained a quote from the research from the University of Liverpool, "Twin pregnancies are at increased risk of preterm delivery compared with singleton gestations, which suggests that there is twin-specific risk to preterm delivery in twins. The prevention strategies that are applied to singleton pregnancies, however, have not been shown to
be effective in twin pregnancies. The purpose of this study was to compare the relaxant effect of magnesium sulfate on spontaneous and oxytocin-augmented contractions of human myometrium from singleton and twin pregnancies and to examine whether the effect of oxytocin on magnesium sulfate's potency could be reversed with the use of the oxytocin receptor antagonist, atosiban. Myometrium was obtained at the time of prelabor cesarean section (36-40 weeks of gestation) from women with singleton (n = 23) or twin (n = 12) pregnancy. Isometric tension recordings were made on myometrial strips that were mounted in organ baths that were superfused with physiologic saline solution. Strips were exposed to rising concentrations of magnesium sulfate, and the effect on spontaneous contractions or stimulated with oxytocin (0.5 nmol/L) and in the presence or absence of atosiban (100 nmol/L) was recorded. The contractile characteristics after each application of magnesium sulfate, which included amplitude of contraction and activity integral, were measured. Concentration-response curves were fitted with the use of nonlinear regression and comparison of the negative logarithm of the 50% reduction in activity values. Magnesium sulfate exerted an equal concentration-dependent inhibitory effect on spontaneous myometrial contractions from both singleton and twin myometrium (P > .05). The application of oxytocin produced a significant rightward shift in the concentration-response curves (P < .0001), but no differences were found between pregnancy groups (P > .05). The addition of atosiban shifted concentration-response curves significantly back to the left for amplitude of contraction and activity integral in singletons (P < .0001). However, only activity integral was significantly reversed in twins (P < .01). Magnesium sulfate is equipotent in suppressing contractions in singleton and twin myometrium. Oxytocin (0.5 nmol/L) significantly reduces the tocolytic potency of magnesium sulfate, which may explain, in part, magnesium sulfate's poor efficacy in vivo; however, this can be reversed partially by the use of an oxytocin receptor antagonist.

According to the news editors, the research concluded: "Combination tocolysis that involves oxytocin receptor antagonists requires further investigation."

The news correspondents report that additional information may be obtained from S. Arrowsmith, University of Liverpool, Harris Wellbeing Preterm Birth Res Center, Dept. of Cellular & Mol Physiol, Liverpool, Merseyside, United Kingdom. Additional authors for this research include J. Neilson and S. Wray.

Researchers from University of Liverpool Provide Details of New Studies and Findings in the Area of Pneumonia (Impact of feeding and housing systems on disease incidence in dairy calves)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Lung Diseases and Conditions - Pneumonia are discussed in a new report. According to news reporting originating in Merseyside, United Kingdom, by NewsRx journalists, research stated, "Contentious issues in calf rearing include milk feeding level and single versus group housing. The current study was performed on a high-producing 170 Holstein cow dairy farm to investigate the impact of nutrition and housing on disease incidence."

The news reporters obtained a quote from the research from the University of Liverpool, "Calves (n=100) were allocated in birth order to one of two commonly used feeding strategies. Group A calves were group housed from birth and fed ad libitum milk replacer (MR) via a computerised machine using a single teat, with weaning commencing at 63 days. Group R calves were initially housed in individual pens receiving 2.5 litres of MR twice daily via a bucket until three weeks of age when they were group housed and fed 3 litres of MR twice daily via a group trough with weaning commencing at 56 days. In total, 80 (80 per cent) calves suffered from at least one incident of disease during the period from birth to 12 weeks. Group A calves had a greater risk of disease than group R calves (diarrhoea: OR 3.86 (95 per cent CI 1.67 to 8.9); pneumonia: OR 5.80 (95 per cent CI 2.33 to 14.44)). There was a 5.1 per cent incidence of failure of passive transfer of Ig assessed via measurement of plasma total protein concentrations at 48 hours of age."

According to the news reporters, the research concluded: "It is hypothesised that the increased diarrhoea risk in group A calves was most likely associated with group housing, while the increased pneumonia risk was associated with the use of a single teat allowing increased transmission of pathogens from calf to calf."

For more information on this research see: Impact of feeding and housing systems on disease incidence in dairy calves. Veterinary Record, 2016;179(20):512-50. Veterinary Record can be contacted at: Bmj Publishing Group, British Med Assoc House, Tavistock Square, London WC1H 9JR, England. Researchers from University of Lodz Report Details of New Studies and Findings in the Area of One-Carbon Group Transferases
(Pharmacological inhibition of arginine and lysine methyltransferases induces nuclear abnormalities and suppresses ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Enzymes and Coenzymes - One-Carbon Group Transferases. According to news reporting originating in Lodz, Poland, by NewsRx journalists, research stated, "Posttranslational modifications of histone tails can alter chromatin structure and regulate gene transcription. While recent studies implicate the lysine/arginine protein methyltransferases in the regulation of genes for endothelial metabolism, the role of AMI-1 and AMI-5 compounds in angiogenesis remains unknown."

Financial support for this research came from National Science Centre.

The news reporters obtained a quote from the research from the University of Lodz, "Here, we show that global inhibition of arginine and lysine histone methyltransferases (HMTs) by AMI-5 induced an angiostatic profile in human microvascular endothelial cells and human umbilical vein endothelial cells. Based on FACS analysis, we found that inhibition of HMTs significantly affects proliferation of endothelial cells, by suppressing cell cycle progression in the Go/G1 phase. Immunofluorescent studies of the endothelial cells replication pattern by 5-ethynyl-2'-deoxyuridine incorporation disclosed that AMI-5, and the arginine methyltransferase inhibitor AMI-1, induced heterochromatin formation and a number of nuclear abnormalities, such as formation of micronuclei (MNs) and nucleoplasmic bridges (NPBs), which are markers of chromosomal instability."

According to the news reporters, the research concluded: "In addition to the modification of the cell cycle machinery in response to AMI5 treatment, also endothelial cells migration and capillary-like tube formation processes were significantly inhibited, implicating a stimulatory role of HMTs in angiogenesis."

Our news correspondents report that additional information may be obtained by contacting A. Balcerczyk, University of Lodz, Dept. of Mol Biophys, Lodz, Poland. Additional authors for this research include D. Rybczék, M. Wojtala, L. Pirola, J. Okabe and A. El-Osta.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1016/j.bcp.2016.09.013. This DOI is a link to an online electronic document that is either free or for purchase.

Researchers from University of Lodz Report New Studies and Findings in the Area of Bladder Cancer (Genetic diversity of urinary bladder cancer and the risk of recurrence based on mutation analysis)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Oncology - Bladder Cancer is the subject of a report. According to news reporting from Lodz, Poland, by NewsRx journalists, research stated, "The aim of the study was to assess the genetic diversity of bladder cancer and determine the suitability of a proposed molecular marker panel to monitor the course of bladder cancer patients. The study involved 185 patients with diagnosed bladder cancer."

The news correspondents obtained a quote from the research from the University of Lodz, "The genetic diversity of the bladder cancer was evaluated by the prevalence of mutations in the TP53, HRAS, FGFR3 and WWOX genes. Mutations were detected in 62.2% of the tumor samples. The most frequently mutated genes were FGFR3 (49.7%) and TP53 (16.2%). No mutation was observed in the WWOX gene. FGFR3 mutations, contrary to TP53, correlated with lower tumor stage and grade, and the presence of multiple tumors. The risk of death was significantly higher in patients with TP53 mutant tumors (HR=3.12; 95%CI: 1.14-7.27; p=0.006) but lower in patients with FGFR3 mutations (HR=0.36; 95%CI: 0.15-0.87; p=0.002). None of the investigated genes was an independent predictor of disease-specific survival, recurrence-free survival or progression-free survival. The results confirm the existence of two alternative pathways of bladder cancer. However the presence of a high percentage of wild type variants in the higher stages of the disease suggest the existence of another pathway of molecular changes leading to the development of bladder cancer."

According to the news reporters, the research concluded: "Molecular analysis may have prognostic value and may facilitate the assignment of patients to appropriate forms of treatment - especially in the case of patients with a T1 tumor, where different mutational patterns were observed in each grade."

For more information on this research see: Genetic diversity of urinary bladder cancer and the risk of recurrence based on mutation analysis. Neoplasma, 2016;63(6):952-960. Neoplasma can be contacted at: Aepress Sro, Bajzova 7, Bratislava, 821 08, Slovakia.

Researchers from University of Louisville Describe Findings in Diabetes (Diabetic Microvascular Disease and Pulmonary Fibrosis: The Contribution of Platelets and Systemic Inflammation)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Diabetes have been published. According to news reporting originating in Louisville, Kentucky, by NewsRx journalists, research stated, "Diabetes is strongly associated with systemic inflammation and oxidative stress, but its effect on pulmonary vascular disease and lung function has often been disregarded. Several studies identified restrictive lung disease and fibrotic changes in diabetic patients and in animal models of diabetes."

The news reporters obtained a quote from the research from the University of Louisville, "While microvascular dysfunction is a well-known complication of diabetes, the mechanisms leading to diabetes-induced lung injury have largely been disregarded. We described the potential involvement of diabetes-induced platelet-endothelial interactions in perpetuating vascular inflammation and oxidative injury leading to fibrotic changes in the lung. Changes in nitric oxide synthase (NOS) activation and decreased NO bioavailability in the diabetic lung increase platelet activation and vascular injury and may account for platelet hyperreactivity reported in diabetic patients. Additionally, the Janus kinase/signal transducer and activator of transcription (JAK/STAT) pathway has been reported to mediate pancreatic islet damage, and is implicated in the onset of diabetes, inflammation and vascular injury. Many growth factors and diabetes-induced agonists act via the JAK/STAT pathway. Other studies reported the contribution of the JAK/STAT pathway to the regulation of the pulmonary fibrotic process but the role of this pathway in the development of diabetic lung fibrosis has not been considered."

According to the news reporters, the research concluded: "These observations may open new therapeutic perspectives for modulating multiple pathways to mitigate diabetes onset or its pulmonary consequences."

For more information on this research see: Diabetic Microvascular Disease and Pulmonary Fibrosis: The Contribution of Platelets and Systemic Inflammation. *International Journal of Molecular Sciences*, 2016;17(11):1398-1411. *International Journal of Molecular Sciences* can be contacted at: Mdpi Ag, St Alban-Anlage 66, Ch-4052 Basel, Switzerland.

Researchers from University of Lubeck Describe Findings in Parkinson's Disease (Genetics of Parkinson's disease)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Parkinson's disease. According to news reporting originating in Lubeck, Germany, by NewsRx editors, the research stated, "Almost two decades after the identification of SNCA as the first causative gene in Parkinson's disease (PD) and the subsequent understanding that genetic factors play a substantial role in PD development, our knowledge of the genetic architecture underlying this disease has vastly improved. Approximately 5 -10% of patients suffer from a monogenic form of PD where autosomal dominant mutations in SNCA, LRRK2, and VPS35 and autosomal recessive mutations in PINK1, DJ-1, and Parkin cause the disease with high penetrance."

The news reporters obtained a quote from the research from the University of Lubeck, "Furthermore, recent whole-exome sequencing have described autosomal recessive DNAJC6 mutations in predominately atypical, but also cases with typical PD. In addition, several other genes have been linked to atypical Parkinsonian phenotypes. However, the vast majority of PD is genetically complex, i.e. it is caused by the combined action of common genetic variants in concert with environmental factors. By the application of genome-wide association studies, 26 PD risk loci have been established to date. Similar to other genetically complex diseases, these show only moderate effects on PD risk. Increasing this etiologic complexity, many of the involved genetic and environmental risk factors likely interact in an intricate fashion."

According to the news reporters, the research concluded: "This article aims to provide a comprehensive overview of the current knowledge in PD genetics."

Our news correspondents report that additional information may be obtained by contacting C.M. Lill, University of Lubeck, Inst Neurogenet, Genet & Mol Epidemiol Grp, D-23562 Lubeck, Germany.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1016/j.mcp.2016.11.001. This DOI is a link to an online electronic document that is either free or for purchase.

Researchers from University of Lyon Discuss Findings in Toxicology and Pharmacology (Optimizing the design of a reproduction toxicity test with the pond snail Lymnaea stagnalis)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Drugs and Therapies - Toxicology and Pharmacology is the subject of a report. According to news reporting originating from Villeurbanne, France, by NewsRx correspondents, research stated, "This paper presents the results from two ring-tests addressing the feasibility, robustness and reproducibility of a reproduction toxicity test with the freshwater gastropod Lymnaea stagnalis (RENILYS strain). Sixteen laboratories (from inexperienced to expert laboratories in mollusc testing) from nine countries participated in these ring-tests."

Financial supporters for this research include Danish EPA, DEFR, INRA, ONEMA, UBA.

Our news editors obtained a quote from the research from the University of Lyon, "Survival and reproduction were evaluated in L. stagnalis exposed to cadmium, tributyltin, prochloraz and trenbolone according to an OECD draft Test Guideline. In total, 49 datasets were analysed to assess the practicability of the proposed experimental protocol, and to estimate the between-laboratory reproducibility of toxicity endpoint values. The statistical analysis of count data (number of clutches or eggs per individual-day) leading to ECx estimation was specifically developed and automated through a free web-interface. Based on a complementary statistical analysis, the optimal test duration was established and the most sensitive and cost-effective reproduction toxicity endpoint was identified, to be used as the core endpoint."

According to the news editors, the research concluded: "This validation process and the resulting optimized protocol were used to consolidate the OECD Test Guideline for the evaluation of reproductive effects of chemicals in L stagnalis."

For more information on this research see: Optimizing the design of a reproduction toxicity test with the pond snail Lymnaea stagnalis. Regulatory Toxicology and Pharmacology, 2016;81():47-56. DNA Research

Researchers from University of Malaysia Detail Findings in DNA Research (Gold nanoparticle mediated method for spatially resolved deposition of DNA on nano-gapped interdigitated electrodes, and its application to the detection of the human ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on DNA Research have been presented. According to news reporting originating in Kangar, Malaysia, by NewsRx journalists, research stated, "The authors introduce a method for spatially arranged DNA immobilization on 10-nm gold nanoparticles (GNP) deposited on a silicon substrate carrying nanogapped interdigitated electrodes. The GNPs are covalently bound to the surface via silane chemistry, and the single steps of fabrication are monitored by FTIR spectroscopy and atomic force microscopy."

Financial support for this research came from Ministry of Higher Education, Malaysia.

The news reporters obtained a quote from the research from the University of Malaysia, "This GNP deposition technique is shown to reduce the size of the nanogaps to 130 nm. FTIR also was used to monitor the immobilization of DNA on the surface of the interdigitated electrodes. This method allows DNA to be immobilized in a uniform and homogenous way. The utility of the method is demonstrated by immobilizing probe DNA on the surface and detecting target DNA specific for the human papilloma virus via fluorescence with a detection limit as low as 1 pM."

According to the news reporters, the research concluded: "In our perception, this method for GNP-mediated DNA immobilization enables high-performance sensing of a wide range of target (analyte) DNA."

For more information on this research see: Gold nanoparticle mediated method for spatially resolved deposition of DNA on nano-gapped interdigitated electrodes, and its application to the detection of the human Papillomavirus. Microchimica Acta, 2016;183 (12):3119-3126. Microchimica Acta can be contacted at: Springer Wien, Sachsenplatz 4-6, PO Box 89, A-1201 Wien, Austria. Researchers from University of Manchester Describe Findings in Pharmacology [First-in-Class Chemical Probes against Poly(ADP-ribose) Glycohydrolase (PARG) Inhibit DNA Repair with Differential Pharmacology to Olaparib]

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Pharmacology. According to news reporting originating from Manchester, United Kingdom, by NewsRx correspondents, research stated, "The enzyme poly(ADP-ribose) glycohydrolase (PARG) performs a critical role in the repair of DNA single strand breaks (SSBs). However, a detailed understanding of its mechanism of action has been hampered by a lack of credible, cell-active chemical probes."

Financial support for this research came from Cancer Research UK.

Our news editors obtained a quote from the research from the University of Manchester, "Herein, we demonstrate inhibition of PARG with a small molecule, leading to poly(ADP-ribose) (PAR) chain persistence in intact cells. Moreover, we describe two advanced, and chemically distinct, cell-active tool compounds with convincing on-target pharmacology and selectivity. Using one of these tool compounds, we demonstrate pharmacology consistent with PARG inhibition. Further, while the roles of PARG and poly(ADP-ribose) polymerase (PARP) are closely intertwined, we demonstrate that the pharmacology of a PARG inhibitor differs from that observed with the more thoroughly studied PARP inhibitor olaparib."

According to the news editors, the research concluded: "We believe that these tools will facilitate a wider understanding of this important component of DNA repair and may enable the development of novel therapeutic agents exploiting the critical dependence of tumors on the DNA damage response (DDR)."

For more information on this research see: First-in-Class Chemical Probes against Poly(ADP-ribose) Glycohydrolase (PARG) Inhibit DNA Repair with Differential Pharmacology to Olaparib. ACS Chemical Biology, 2016;11(11):3179-3190. ACS Chemical Biology can be contacted at: Amer Chemical Soc, 1155 16TH St, NW, Washington, DC 20036, USA. Researchers from University of Manchester Detail New Studies and Findings in the Area of Kidney Transplants (Renal Allograft Failure After Ipilimumab Therapy for Metastatic Melanoma: A Case Report and Review of the Literature)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Transplant Medicine - Kidney Transplants is now available. According to news reporting out of Manchester, United Kingdom, by NewsRx editors, research stated, "Transplant recipients are at an increased risk of malignant melanoma, a result of chronic immunosuppression. Ipilimumab is a newer biological agent targeting T lymphocytes to potentiate an immune response against melanoma, and the use of this agent results in a new adverse effect profile that the clinician must be aware of while a patient is on therapy."

Our news journalists obtained a quote from the research from the University of Manchester, "We report the case of a male renal transplant recipient who developed graft failure while treated with ipilimumab and minimal immunosuppressive therapy for metastatic ocular melanoma, with biopsy evidence of glomerulonephritis and acute rejection. We highlight the immunological side effects that can manifest from ipilimumab therapy and conclude that it did influence graft function in this patient."

According to the news editors, the research concluded: "Our case illustrates the importance of weighing the risks and benefits to graft function and long-term survival as well as the importance of considering other treatment modalities in this specific group of melanoma patients."

Our news journalists report that additional information may be obtained by contacting A. Jose, University of Manchester, Manchester, Lancs, United Kingdom. Additional authors for this research include P. Yiannoullou, S. Bhutani, H. Denley, M. Morton, M. Picton, A. Summers, D. van Dehen and T. Augustine.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1016/j.transproceed.2016.07.019. This DOI is a link to an online electronic document that is either free or for purchase.

Researchers from University of Manchester Provide Details of New Studies and Findings in the Area of Breast Cancer (Patient-derived Mammosphere and Xenograft Tumour Initiation Correlates with Progression to Metastasis)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Oncology - Breast Cancer have been presented. According to news reporting originating in Manchester, United Kingdom, by NewsRx journalists, research stated, "Breast cancer specific mortality results from tumour cell dissemination and metastatic colonisation. Identification of the cells and processes responsible for metastasis will enable better prevention and control of metastatic disease, thus reducing relapse and mortality."

Financial support for this research came from Breast Cancer Now.

The news reporters obtained a quote from the research from the University of Manchester, "To better understand these processes, we prospectively collected 307 patient-derived breast cancer samples (n = 195 early breast cancers (EBC) and n = 112 metastatic samples (MBC)). We assessed colony-forming activity in vitro by growing isolated cells in both primary (formation) and secondary (self-renewal) mammosphere culture, and tumour initiating activity in vivo through subcutaneous transplantation of fragments or cells into mice. Metastatic samples formed primary mammosphere colonies significantly more frequently than early breast cancers and had significantly higher primary mammosphere colony formation efficiency (0.9 % vs. 0.6 %; p< 0.0001). Tumour initiation in vivo was significantly higher in metastatic than early breast cancer samples (63 % vs. 38 %, p = 0.04). Of 144 breast cancer samples implanted in vivo, we established 20 stable patient-derived xenograft (PDX) models at passage 2 or greater. Lung metastases were detected in mice from 14 PDX models. Mammosphere colony formation in vitro significantly correlated with the ability of a tumour to metastasise to the lungs in vivo (p = 0.05), but not with subcutaneous tumour initiation. In summary, the breast cancer stem cell activities of colony formation and tumour initiation are increased in metastatic compared to early samples, and predict metastasis in vivo."

According to the news reporters, the research concluded: "These results suggest that breast stem cell activity will predict for poor outcome tumours, and therapy targeting this activity will improve outcomes for patients with metastatic disease."

The direct object identifier (DOI) for that additional information is:
Researchers from University of Manitoba Provide Details of New Studies and Findings in the Area of Phenethylamines (Reduction of blood pressure by store-operated calcium channel blockers)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Phenethylamines. According to news reporting from Winnipeg, Canada, by NewsRx journalists, research stated, "The voltage-operated Ca(2+) channels (VOCC), which allow Ca(2+) influx from the extracellular space, are inhibited by anti-hypertensive agents such as verapamil and nifedipine. The Ca(2+) entering from outside into the cell triggers Ca(2+) release from the sarcoplasmic reticulum (SR) stores."

Financial support for this research came from St. Boniface Hospital Research Foundation.

The news correspondents obtained a quote from the research from the University of Manitoba, "To refill the depleted Ca(2+) stores in the SR, another type of Ca(2+) channels in the cell membrane, known as store-operated Ca(2+) channels (SOCC), are activated. These SOCCs are verapamil and nifedipine resistant, but are SKF 96465 (SK) and gadolinium (Gd(3+)) sensitive. Both SK and Gd(3+) have been shown to reduce [Ca(2+)]i in the smooth muscle, but their effects on blood pressure have not been reported. Our results demonstrated that both SK and Gd(3+) produced a dose-dependent reduction in blood pressure in rat. The combination of SK and verapamil produced an additive action in lowering the blood pressure. Furthermore, SK, but not Gd(3+) suppressed proliferation of vascular smooth muscle cells in the absence or presence of lysophosphatidic acid (LPA). SK decreased the elevation of [Ca(2+)]i induced by LPA, endothelin-1 (ET-1) and angiotensin II (Ang II), but did not affect the norepinephrine (NE)-evoked increase in [Ca(2+)]i. On the other hand, Gd(3+) inhibited the LPA and Ang II induced change in [Ca(2+)]i, but had no effect on the ET-1 and NE induced increase in [Ca(2+)]i. The combination of verapamil and SK abolished the LPA-or adenosine-5'-triphosphate (ATP)-induced [Ca(2+)]i augmentation."

According to the news reporters, the research concluded: "These results suggest that SOCC inhibitors, like VOCC blocker, may serve as promising drugs for the treatment of hypertension."

For more information on this research see: Reduction of blood pressure by store-operated calcium channel blockers. Journal of Cellular and Molecular Medicine, 2015;19 (12):2763-70. Journal of Cellular and Molecular Medicine can be contacted at: Blackwell Publishing Inc, 350 Main St, Malden, MA 02148, USA. Gram-Negative Bacteria - Acinetobacter baumannii

Researchers from University of Maryland Provide Details of New Studies and Findings in the Area of Acinetobacter baumannii (Use of Comparative Genomics To Characterize the Diversity of Acinetobacter baumannii Surveillance Isolates in a Health ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Gram-Negative Bacteria - Acinetobacter baumannii have been published. According to news reporting originating in Baltimore, Maryland, by NewsRx journalists, research stated, "Despite the increasing prevalence of the nosocomial pathogen Acinetobacter baumannii, little is known about which genomic components contribute to clinical presentation of this important pathogen. Most whole-genome comparisons of A. baumannii have focused on specific genomic regions associated with phenotypes in a limited number of genomes."

Financial supporters for this research include National Institutes of Health, DTRA and DOD, HHS | National Institutes of Health (NIH).

The news reporters obtained a quote from the research from the University of Maryland, "In this work, we describe the results of a whole-genome comparative analysis of 254 surveillance isolates of Acinetobacter species, 203 of which were A. baumannii, isolated from perianal swabs and sputum samples collected as part of an infection control active surveillance program at the University of Maryland Medical Center. The collection of surveillance isolates includes both carbapenem-susceptible and -resistant isolates. Based on the whole-genome phylogeny, the A. baumannii isolates collected belong to two major phylogenomic lineages. Results from multilocus sequence typing indicated that one of the major phylogenetic groups of A. baumannii was comprised solely of strains from the international clonal lineage 2. The genomic content of the A. baumannii isolates was examined using large-scale BLAST score ratio analysis to identify genes that are associated with carbapenem-susceptible and -resistant isolates, as well as genes potentially associated with the source of isolation. This analysis revealed a number of genes that were exclusive or at greater frequency in each of these classifications."
According to the news reporters, the research concluded: "This study is the most comprehensive genomic comparison of Acinetobacter isolates from a surveillance study to date and provides important information that will contribute to our understanding of the success of A. baumannii as a human pathogen."

For more information on this research see: Use of Comparative Genomics To Characterize the Diversity of Acinetobacter baumannii Surveillance Isolates in a Health Care Institution. Antimicrobial Agents and Chemotherapy, 2016;60(10):5933-5941. Antimicrobial Agents and Chemotherapy can be contacted at: Amer Soc Microbiology, 1752 N St NW, Washington, DC 20036-2904, USA. Hematologic Diseases and Conditions - Anemia

Researchers from University of Maryland Report Details of New Studies and Findings in the Area of Anemia [Clinical Trypanosoma cruzi Disease after Cardiac Transplantation in a Cynomolgus Macaque (Macaca fascicularis)]

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Hematologic Diseases and Conditions - Anemia is the subject of a report. According to news reporting out of Baltimore, Maryland, by NewsRx editors, research stated, "A cynomolgus macaque received a heterotopic cardiac allograft as part of a transplant study, with monoclonal antibodies targeted to specific immune costimulation molecules (CD154, CD28) but no traditional immunosuppressive therapy after surgery. Clinical anemia was detected on postoperative day (POD) 35 and had worsened (Hgb, 2.3 g/dL; Hct = 7.3%) by POD 47, despite type-matched whole-blood transfusions."

Our news journalists obtained a quote from the research from the University of Maryland, "After a total of 4 blood transfusions, hematologic parameters were improved (Hgb, 5.9 g/dL; Hct, 18.7%). On POD 50, a peripheral blood smear revealed trypomastigotes, and qualitative RT-PCR of whole blood identified the organism as Trypanosoma cruzi. Although clinically stable initially, the macaque soon developed sufficient weight loss to necessitate euthanasia on POD 64. The final diagnosis was clinical anemia due to T. cruzi infection."

According to the news editors, the research concluded: "This study represents the first reported case of Chagas disease after heart transplant in a NHP."
For more information on this research see: Clinical Trypanosoma cruzi Disease after Cardiac Transplantation in a Cynomolgus Macaque (Macaca fascicularis). *Comparative Medicine*, 2016;66(6):494-498. *Comparative Medicine* can be contacted at: Amer Assoc Laboratory Animal Science, 9190 Crestwyn Hills Dr, Memphis, TN 38125, USA.

**Drugs and Therapies - Antiretrovirals**

**Researchers from University of Maryland Report Recent Findings in Antiretrovirals (HIV drug resistance mutations among patients failing second-line antiretroviral therapy in Rwanda)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Drugs and Therapies - Antiretrovirals. According to news originating from Baltimore, Maryland, by NewsRx correspondents, research stated, "Studies of patients failing second-line antiretroviral therapy (ART) in resource-limited settings (RLS) are few. Evidence suggests most patients who appear to be virologically failing do so not due to drug resistance but to poor adherence, which, if properly addressed, could allow continued use of less expensive first- and second-line regimens."

Our news journalists obtained a quote from the research from the University of Maryland, "Drug resistant mutations (DRMs) were characterized among patients virologically failing second-line ART in Rwanda. A total of 128 adult patients receiving second line ART for at least 6 months were invited to participate; 74 agreed and had HIV-1 viral load (VL) measured. Resistance genotypes were conducted in patients with virological failure (VF; that is, VL >= 1,000 copies/ml). In total, 35 patients met the criteria for VF. The median time on lopinavir/ritonavir-based second-line ART was 2.7 years. Of 30 successful resistance genotype analyses, 13 (43%) had nucleoside reverse transcriptase inhibitor (NRTI) mutation, 18 (60%) had at least 1 non-NRTI mutation and 5 (17%) had at least 1 major protease inhibitor mutation. Eleven (37%) had virus without significant mutations that would be fully sensitive to first-line ART; 12 (40%) had DRM to first-line ART but sensitive to second-line ART. Only 7 patients (23%) demonstrated a DRM profile requiring third-line ART. Among 30 genotyped samples of patients with VF on second-line ART, more than one-third had no significant DRMs, implicating poor adherence as the primary cause of VF. The majority of patients (77%) would not have required third-line ART."

According to the news editors, the research concluded: "These findings reinforce the need for intensive adherence assessment and counselling for patients who appear to be failing second-line ART in RLS."

For more information on this research see: HIV drug resistance mutations among

The news correspondents report that additional information may be obtained from D.J. Riedel, University of Maryland, Sch Med, Div Infect Dis, Baltimore, MD 21201, United States. **Pharmacoepidemiology**

**Researchers from University of Massachusetts Report on Findings in Pharmacoepidemiology (Probabilistic bias analysis in pharmacoepidemiology and comparative effectiveness research: a systematic review)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Pharmacoepidemiology is the subject of a report.

According to news reporting out of Worcester, Massachusetts, by NewsRx editors, research stated, "We systematically reviewed pharmacoepidemiologic and comparative effectiveness studies that use probabilistic bias analysis to quantify the effects of systematic error including confounding, misclassification, and selection bias on study results. We found articles published between 2010 and October 2015 through a citation search using Web of Science and Google Scholar and a keyword search using PubMed and Scopus."

Our news journalists obtained a quote from the research from the University of Massachusetts, "Eligibility of studies was assessed by one reviewer. Three reviewers independently abstracted data from eligible studies. Fifteen studies used probabilistic bias analysis and were eligible for data abstraction-nine simulated an unmeasured confounder and six simulated misclassification. The majority of studies simulating an unmeasured confounder did not specify the range of plausible estimates for the bias parameters. Studies simulating misclassification were in general clearer when reporting the plausible distribution of bias parameters. Regardless of the bias simulated, the probability distributions assigned to bias parameters, number of simulated iterations, sensitivity analyses, and diagnostics were not discussed in the majority of studies. Despite the prevalence and concern of bias in pharmacoepidemiologic and comparative effectiveness studies, probabilistic bias analysis to quantitatively model the effect of bias was not widely used. The quality of reporting and use of this technique varied and was often unclear."

According to the news editors, the research concluded: "Further discussion and dissemination of the technique are warranted."

For more information on this research see: Probabilistic bias analysis in

Liver Diseases and Conditions - Hepatitis C Virus

Researchers from University of Massachusetts School of Medicine Describe Findings in Hepatitis C Virus (Structural and Thermodynamic Effects of Macrocyclization in HCV NS3/4A Inhibitor MK-5172)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Liver Diseases and Conditions - Hepatitis C Virus is the subject of a report. According to news reporting from Worcester, Massachusetts, by NewsRx journalists, research stated, "Recent advances in direct-acting antivirals against Hepatitis C Virus (HCV) have led to the development of potent inhibitors, including MK-5172, that target the viral NS3/4A protease with relatively low susceptibility to resistance. MK-5172 has a P2-P4 macrocycle and a unique binding mode among current protease inhibitors where the P2 quinoxaline packs against the catalytic residues H57 and D81."

Financial supporters for this research include National Institute of Allergy and Infectious Diseases, Office of Science, National Institute of General Medical Sciences.

The news correspondents obtained a quote from the research from the University of Massachusetts School of Medicine, "However, the effect of macrocyclization on this binding mode is not clear, as is the relation between macrocyclization, thermodynamic stabilization, and susceptibility to the resistance mutation A156T. We have determined high-resolution crystal structures of linear and P1-P3 macrocyclic analogs of MK-5172 bound to WT and A156T protease and compared these structures, their molecular dynamics, and experimental binding thermodynamics to the parent compound. We find that the 'unique' binding mode of MK-5172 is conserved even when the P2-P4 macrocycle is removed or replaced with a P1-P3 macrocycle. While beneficial to decreasing the entropic penalty associated with binding, the constraint exerted by the P2-P4 macrocycle prevents efficient rearrangement to accommodate the A156T mutation, a deficit alleviated in the linear and P1-P3 analogs."

According to the news reporters, the research concluded: "Design of macrocyclic inhibitors against NS3/4A needs to achieve the best balance between exerting optimal conformational constraint for enhancing potency, fitting within the substrate envelope and allowing adaptability to be robust against resistance mutations."

For more information on this research see: Structural and Thermodynamic Effects of

Our news journalists report that additional information may be obtained by contacting D.I. Soumana, Dept. of Biochemistry and Molecular Pharmacology, University of Massachusetts Medical School, 364 Plantation Street, Worcester, Massachusetts 01605, United States. **Vascular Diseases**

**Researchers from University of Melbourne Detail Findings in Vascular Diseases (Fetuin-A-containing calciprotein particles in mineral trafficking and vascular disease)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Vascular Diseases are presented in a new report. According to news reporting out of Parkville, Australia, by NewsRx editors, research stated, "Calcium and phosphate combine to form insoluble precipitates in both inorganic and organic materials. This property is useful biologically and has been used by numerous organisms to create hard tissues, a process referred to as biomineralisation [1]."

Financial support for this research came from National Health and Medical Research Council (NHMRC).

Our news journalists obtained a quote from the research from the University of Melbourne, "In humans, calcium and phosphate combine to form useful crystal structures largely composed of calcium hydroxyapatite [Ca-10(PO4)(6)(OH)(2)] and these are essential in the growth, maintenance and strength of parts of the skeleton and other structures like teeth. However, it remains unclear how the body achieves the exquisite specificity involved in biomineralisation. In ageing and disease, these pathways are perturbed, resulting in ectopic calcium crystal deposition impairing tissue function and, interestingly, frequently accompanied by simultaneous loss of mineral from sites where it is useful (e.g. bone). One paradigm for this maladaptive situation is renal failure; a situation that we know is associated with vascular stiffening and calcification, along with mineral loss from the skeleton."

According to the news editors, the research concluded: "Mineral trafficking is a loose term used to describe the movements of calcium salts around the body, and new insights into these pathways may explain some of the problems of previous models of bone mineral disease in renal failure and point to potential future therapeutic strategies."

For more information on this research see: Fetuin-A-containing calciprotein
Researchers from University of Messina Discuss Findings in Cerebellar Ataxia [Cerebellar ataxia and severe muscle CoQ(10) deficiency in a patient with a novel mutation in ADCK3]

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Central Nervous System Diseases and Conditions - Cerebellar Ataxia have been presented. According to news reporting originating in Messina, Italy, by NewsRx journalists, research stated, "Inherited ataxias are a group of heterogeneous disorders in children or adults but their genetic definition remains still undetermined in almost half of the patients. However, CoQ(10) deficiency is a rare cause of cerebellar ataxia and ADCK3 is the most frequent gene associated with this defect."

The news reporters obtained a quote from the research from the University of Messina, "We herein report a 48 year old man, who presented with dysarthria and walking difficulties. Brain magnetic resonance imaging showed a marked cerebellar atrophy. Serum lactate was elevated. Tissues obtained by muscle and skin biopsies were studied for biochemical and genetic characterization. Skeletal muscle biochemistry revealed decreased activities of complexes I+III and II+III and a severe reduction of CoQ(10), while skin fibroblasts showed normal CoQ(10) levels. A mild loss of maximal respiration capacity was also found by high-resolution respirometry. Molecular studies identified a novel homozygous deletion (c.504del_CT) in ADCK3, causing a premature stop codon. Western blot analysis revealed marked reduction of ADCK3 protein levels. Treatment with CoQ(10) was started and, after 1 year follow-up, patient neurological condition slightly improved. This report suggests the importance of investigating mitochondrial function and, in particular, muscle CoQ(10) levels, in patients with adult-onset cerebellar ataxia."

According to the news reporters, the research concluded: "Moreover, clinical stabilization by CoQ(10) supplementation emphasizes the importance of an early diagnosis."

For more information on this research see: Cerebellar ataxia and severe muscle CoQ(10) deficiency in a patient with a novel mutation in ADCK3. Clinical Genetics, 2016;90 (2):156-160. Clinical Genetics can be contacted at: Wiley-Blackwell, 111 River St, Hoboken
Researchers from University of Michigan Detail New Studies and Findings in the Area of RNA-Directed DNA Polymerase (Structural and functional consequences of a disease mutation in the telomere protein TPP1)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Enzymes and Coenzymes - RNA-Directed DNA Polymerase. According to news originating from Ann Arbor, Michigan, by NewsRx correspondents, research stated, "Telomerase replicates chromosome ends to facilitate continued cell division. Mutations that compromise telomerase function result in stem cell failure diseases, such as dyskeratosis congenita (DC)."

Financial support for this research came from HHS | National Institutes of Health (NIH).

Our news journalists obtained a quote from the research from the University of Michigan, "One such mutation (K170 Delta), residing in the telomerase-recruitment factor TPP1, provides an excellent opportunity to structurally, biochemically, and genetically dissect the mechanism of such diseases. We show through site-directed mutagenesis and X-ray crystallography that this TPP1 disease mutation deforms the conformation of two critical amino acids of the TEL [TPP1’s glutamate (E) and leucine-rich (L)] patch, the surface of TPP1 that binds telomerase. Using CRISPR-Cas9 technology, we demonstrate that introduction of this mutation in a heterozygous manner is sufficient to shorten telomeres in human cells. Our findings rule out dominant-negative effects of the mutation. Instead, these findings implicate reduced TEL patch dosage in causing telomere shortening."

According to the news editors, the research concluded: "Our studies provide mechanistic insight into telomerase-deficiency diseases and encourage the development of gene therapies to counter such diseases."

Researchers from University of Michigan Report Details of New Studies and Findings in the Area of Basal Ganglia (An oxytocin receptor polymorphism predicts amygdala reactivity and antisocial behavior in men)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Central Nervous System - Basal Ganglia. According to news reporting from Ann Arbor, Michigan, by NewsRx journalists, research stated, "Variability in oxytocin (OXT) signaling is associated with individual differences in sex-specific social behavior across species. The effects of OXT signaling on social behavior are, in part, mediated through its modulation of amygdala function."

The news correspondents obtained a quote from the research from the University of Michigan, "Here, we use imaging genetics to examine sex-specific effects of three single-nucleotide polymorphisms in the human oxytocin receptor gene (OXTR; rs1042778, rs53576 and rs2254298) on threat-related amygdala reactivity and social behavior in 406 Caucasians. Analyses revealed that among men but not women, OXTR rs1042778 TT genotype was associated with increased right amygdala reactivity to angry facial expressions, which was uniquely related to higher levels of antisocial behavior among men. Moderated mediation analysis suggested a trending indirect effect of OXTR rs1042778 TT genotype on higher antisocial behavior via increased right amygdala reactivity to angry facial expressions in men. Our results provide evidence linking genetic variation in OXT signaling to individual differences in amygdala function."

According to the news reporters, the research concluded: "The results further suggest that these pathways may be uniquely important in shaping antisocial behavior in men."

Our news journalists report that additional information may be obtained by contacting L.W. Hyde, University of Michigan, Center Human Growth & Dev, Ann Arbor, MI 48109, United States. Additional authors for this research include N.S. Corral-Frias, B. Vannucci, R. Bogdan, A.R. Knodt, A.R. Hariri and L.W. Hyde.

Heart Disorders and Diseases - Heart Failure

Researchers from University of Michigan Report Findings in Heart Failure (Recruitment And Retention Challenges Of Examining Cognitive Dysfunction In Older Adults Hospitalized For Acute Heart Failure)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Heart Disorders and Diseases - Heart Failure. According to news reporting originating from Ann Arbor, Michigan, by NewsRx correspondents, research stated, "Barriers to recruiting and retaining acutely ill older adults in clinical research include complexity of illness, fatigue, and early discharge. To describe recruitment and retention challenges of examining cognitive dysfunction in older adults hospitalized for acute heart failure."

Our news editors obtained a quote from the research from the University of Michigan, "An examination of the reasons for recruitment and retention issues within an acute care, university-affiliated health care system. Sixty-two patients refused to participate for a variety of reasons; 11 were ineligible, and 27 participants who completed initial data collection refused to participate further because they were too tired, were being discharged on the day of data collection, or were discharged before the next data collection day. Multiple barriers to the recruitment and retention of older adults hospitalized for acute heart failure were identified."

According to the news editors, the research concluded: "Strategies are needed to augment recruitment and retention efforts, including expanding the number of data collection sites and allocating sufficient support resources."

For more information on this research see: Recruitment And Retention Challenges Of Examining Cognitive Dysfunction In Older Adults Hospitalized For Acute Heart Failure. American Journal of Critical Care, 2016;25(5):418–421. American Journal of Critical Care can be contacted at: Amer Assoc Critical Care Nurses, 101 Columbia, Aliso Viejo, CA 92656, USA.

Researchers from University of Michigan Report Findings in Plasma
[Comparative analysis of circulating tumor DNA stability In K(3)EDTA, Streck, and CellSave blood collection tubes]

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Hematology - Plasma are presented in a new report. According to news reporting originating in Ann Arbor, Michigan, by NewsRx journalists, research stated, "Optimal conditions for blood collection for circulating tumor DNA (ctDNA) are still being developed. Although both Streckic and EDTA tubes are commonly used, their ability to stabilize ctDNA as a function of time and temperature post-collection has not been thoroughly studied."

The news reporters obtained a quote from the research from the University of Michigan, "Additionally, the potential utility of CellSave tubes (commonly used for circulating tumor cell) for ctDNA measurements has not been studied. Blood was collected into Streck, EDTA, and CellSave tubes from ten patients with metastatic breast cancer enrolled in the MI-ONCOSEQ tumor sequencing program at the University of Michigan and kept either on ice or at room temperature until plasma isolation. Plasma was processed after 2, 6, and 48 h post-collection. We used droplet digital PCR (ddPCR) to quantify plasma ctDNA and wild-type DNA for six patients who had tumor tissue mutations represented in commercially available ddPCR assays. ctDNA abundance was similar and stable for up to 6 h in all tube types, and there was no effect of storage temperature on the yield for Streck and EDTA tubes. After 48 h, however, one out of four patients with detectable ctDNA showed a 50% decline in ctDNA in the EDTA tube, and three out of six patients showed a 2-3-fold increase in wild-type DNA in the EDTA tube. Streckic, EDTA, and CellSave tubes showed similar performance in preserving ctDNA for up to 6 h before plasma isolation."

According to the news reporters, the research concluded: "Streck and CellSave tubes more consistently stabilized ctDNA and wild-type DNA at 48 h than EDTA tubes."

For more information on this research see: Comparative analysis of circulating tumor DNA stability In K(3)EDTA, Streck, and CellSave blood collection tubes. Clinical Biochemistry, 2016;49(18):1354-1360. Clinical Biochemistry can be contacted at: Pergamon-Elsevier Science Ltd, The Boulevard, Langford Lane, Kidlington, Oxford OX5 1GB, England. (Elsevier - www.elsevier.com; Clinical Biochemistry - www.journals.elsevier.com/clinical-biochemistry/)

Researchers from University of Milan Report Details of New Studies and Findings in the Area of Lymphoma (Multimodal Imaging of Vitreoretinal Lymphoma)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Oncology - Lymphoma. According to news reporting originating from Milan, Italy, by NewsRx correspondents, research stated, "To assess the characteristics and prevalence of fundus abnormalities in vitreoretinal lymphoma (VRL) using multimodal imaging. We retrospectively reviewed chart and imaging studies of patients diagnosed with VRL."

Our news editors obtained a quote from the research from the University of Milan, "All 10 VRL patients (14 eyes) included in the study showed vitreitis, hyperreflective lesions on near-infrared reflectance imaging, and hypoa autofluorescent lesions on fundus autofluorescence. Other findings included hypofluorescent lesions on fluorescein angiography (79%), hypocyanescent lesions on indocyanine green angiography (77%), small retinal pigment epithelium detachments (PEDs) (71%) and large PEDs (36%) on optical coherence tomography (OCT). Outer retinal layer nodularity was identified on OCT in 93% of cases. Small PEDs corresponded to hyperreflective, hyperautofluorescent, hypofluorescent, hypocyanescent lesions. Multiple signs were present on multi modal imaging in VRL eyes. Lymphomatous infiltration created focal PEDs showing abnormal imaging signals. Outer retinal layer nodularity could represent an additional sign of infiltration."

According to the news editors, the research concluded: "Multimodal imaging may guide physicians in the early diagnosis of VRL."

The news editors report that additional information may be obtained by contacting F. Viola, University of Milan, Ophthalmol Unit, Dept. of Clin Sci & Community Hlth, Ca Granda FdnOsped Maggiore Policinico, Milan, Italy. Additional authors for this research include A. Invernizzi, G. Borteselli, M. Pellegrini, E. Tabacchi, G. Staurenghi and F. Viola.

Researchers from University of Minho Report Details of New Studies and Findings in the Area of Citrobacter freundii (Characterization and genome sequencing of a Citrobacter freundii phage CfP1 harboring a lysin active against ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Gram-Negative Bacteria - Citrobacter freundii. According to news reporting originating from Braga, Portugal, by NewsRx correspondents, research stated, "Citrobacter spp., although frequently ignored, is emerging as an important nosocomial bacterium able to cause various superficial and systemic life-threatening infections. Considered to be hard-to-treat bacterium due to its pattern of high antibiotic resistance, it is important to develop effective measures for early and efficient therapy."

Financial supporters for this research include Fundacao para a Ciencia e a Tecnologia, COMPETE 2020.

Our news editors obtained a quote from the research from the University of Minho, "In this study, the first myovirus (vB_CfrM_CfP1) lytic for Citrobacter freundii was microbiologically and genomically characterized. Its morphology, activity spectrum, burst size, and biophysical stability spectrum were determined. CfP1 specifically infects C. freundii, has broad host range (> 85 %; 21 strains tested), a burst size of 45 PFU/cell, and is very stable under different temperatures (-20 to 50 A degrees C) and pH (3 to 11) values. CfP1 demonstrated to be highly virulent against multidrug-resistant clinical isolates up to 12 antibiotics, including penicillins, cephalosporins, carbapenems, and fluoroquinolones. Genomically, CfP1 has a dsDNA molecule with 180,219 bp with average GC content of 43.1 % and codes for 273 CDSs. The genome architecture is organized into function-specific gene clusters typical for tailed phages, sharing 46 to 94 % nucleotide identity to other Citrobacter phages. The lysin gene encoding a predicted D-Ala-D-Ala carboxypeptidase was also cloned and expressed in Escherichia coli and its activity evaluated in terms of pH, ionic strength, and temperature. The lysine optimum activity was reached at 20 mM HEPES, pH 7 at 37 A degrees C, and was able to significantly reduce all C. freundii (> 2 logs) as well as Citrobacter koseri (> 4 logs) strains tested. Interestingly, the antimicrobial activity of this enzyme was performed without the need of pretreatment with outer membrane-destabilizing agents."

According to the news editors, the research concluded: "These results indicate that CfP1 lysin is a good candidate to control problematic Citrobacter infections, for which current antibiotics are no longer effective."

For more information on this research see: Characterization and genome sequencing of a Citrobacter freundii phage CfP1 harboring a lysin active against multidrug-resistant isolates. Applied Microbiology and Biotechnology, 2016;100(24):10543-10553. Applied Microbiology and Biotechnology can be contacted at: Springer, 233 Spring St, New York, NY 10013, USA.
Researchers from University of Minnesota Describe Findings in Inborn Errors of Metabolism (Inborn Errors of Metabolism Collaborative: large-scale collection of data on long-term follow-up for newborn-screened conditions)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Inborn Errors of Metabolism have been published. According to news reporting out of Minneapolis, Minnesota, by NewsRx editors, research stated, "The Inborn Errors of Metabolism Information System (IBEM-IS) collects data on the clinical history of inborn errors of metabolism (IBEMs). The IBEM-IS is accessible to metabolic clinics nationwide and seeks to (i) influence clinical management of affected individuals and (ii) provide information to support public health decision making."

Our news journalists obtained a quote from the research from the University of Minnesota, "Thirty centers in 21 states are enrolling persons with newborn-screened conditions, collecting information on diagnosis and treatment at the time of enrollment and all subsequent visits. Prospective data are collected using electronic capture forms allowing aggregation of information regarding outcomes for individuals affected with IBEMs. A total of 1,893 subjects have been enrolled in the IBEM-IS, and more than 540,000 individual data points have been collected. Data collection has been initiated for subjects with 41 of 46 conditions on the recommended uniform screening panel; 4 conditions have more than 100 subjects enrolled. Median follow-up time for subjects with more than one visit (n = 898) is 1.5 years (interquartile range = 2.2 years). Subjects with critical conditions are more likely to have emergency letters and sick-day plans. Mortality was exclusive to children with critical conditions."

According to the news editors, the research concluded: "Large-scale prospective data can be collected for individuals with rare conditions, permitting enhanced decision making for clinical management and supporting decision making in public health newborn screening programs."

For more information on this research see: Inborn Errors of Metabolism Collaborative: large-scale collection of data on long-term follow-up for newborn-screened
Researchers from University of Minnesota Detail Findings in Medicinal Chemistry (Eeyarestatin I derivatives with improved aqueous solubility)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Health and Medicine - Medicinal Chemistry. According to news reporting out of Minneapolis, Minnesota, by NewsRx editors, research stated, "Inhibition of p97 (also known as valosin-containing protein (VCP)), has been validated as a promising strategy for cancer therapy. Eeyarestatin I (EerI) blocks p97 through a novel mechanism of action and has favorable anti-cancer activities against cultured cancer cells."

Financial support for this research came from University of Minnesota.

Our news journalists obtained a quote from the research from the University of Minnesota, "However, its poor aqueous solubility severely limits its in vivo applications. To circumvent this problem, we have identified EerI derivatives that possess improved aqueous solubility by introducing a single solubilizing group."

According to the news editors, the research concluded: "These modified compounds preserved endoplasmic reticulum (ER) stress-inducing and antiproliferative activities as well as generally good in vitro metabolic properties, suggesting that these Eerl derivatives could serve as candidates for further optimization."

Our news journalists report that additional information may be obtained by contacting L.Q. Chen, University of Minnesota, Academy Hlth Center, Center Drug Design, Minneapolis, MN 55455, United States. Additional authors for this research include T. Zhang,
Researchers from University of Miyazaki Report Findings in Lymphoma
(New-onset haematoproteinuria in a 63-year-old man with intraperitoneal lymph node enlargement)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Oncology - Lymphoma have been published. According to news originating from Miyazaki, Japan, by NewsRx correspondents, research stated, "A 63-year-old man was referred to our hospital because of renal dysfunction with haematoproteinuria. Intraperitoneal lymph node enlargement was also noted."

Our news journalists obtained a quote from the research from the University of Miyazaki, "M protein was not detected by electrophoresis of his serum and urine; however, an increase in the k/l ratio was detected by free light-chain assay. Percutaneous kidney biopsy was performed, and the patient was diagnosed with proliferative glomerulonephritis with monoclonal immunoglobulin deposits. Lymph node biopsy showed follicular lymphoma. Urinalysis findings improved after treatment of the lymphoma. Proliferative glomerulonephritis with monoclonal immunoglobulin deposits is rarely considered to be associated with haematological disease."

According to the news editors, the research concluded: "We report a case of lymphoma-associated proliferative glomerulonephritis with monoclonal immunoglobulin deposits with light-chain abnormality detected by free light-chain assay, but not by electrophoresis."

For more information on this research see: New-onset haematoproteinuria in a 63-year-old man with intraperitoneal lymph node enlargement. *Bmj Case Reports*, 2016;2016(). (BMJ Publishing Group - group.bmj.com/; Bmj Case Reports - casereports.bmj.com/)

The news correspondents report that additional information may be obtained from A. Minakawa, Dept. of Internal Medicine, Division of Circulatory and Body Fluid Regulation, Faculty of Medicine, University of Miyazaki, Miyazaki-City, Miyazaki, Japan. Additional authors for this research include S. Hisanaga, Y. Sato and S. Fujimoto.

Researchers from University of Montpellier Report New Studies and Findings in the Area of Mixed Connective Tissue Disease (Clinical association of mixed connective tissue disease and granulomatosis with polyangiitis: a case report and ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Connective Tissue Diseases and Conditions - Mixed Connective Tissue Disease are presented in a new report. According to news reporting originating from Montpellier, France, by NewsRx correspondents, research stated, "We report here the case of a 50-years-old man treated for mixed connective tissue disease (MCTD) positive for anti-U1 ribonucleoprotein (U1RNP) antibodies who secondarily developed a granulomatosis with polyangiitis (GPA) associated with anti-proteinase 3 anti-neutrophil cytoplasmic antibodies (PR3-ANCA). We then evaluated the frequency of the association between anti-U1RNP and anti-PR3-ANCA antibodies by a systematic retrospective study in ten European hospitals."

Our news editors obtained a quote from the research from the University of Montpellier, "Overall, out of 11,921 samples analyzed for both auto-antibodies, 18 cases of anti-U1RNP and anti-PR3-ANCA double positivity were found and only one patient presented with both MCTD and GPA symptoms. Our retrospective analysis indicates that anti-U1RNP and anti-PR3-ANCA antibodies double positivity is infrequent and very rarely associated with both MCTD and GPA. Our observation describes for the first time the coexistence of MCTD and severe GPA in a Caucasian patient. Association of anti-U1RNP and ANCA antibodies was rarely reported in the literature. Eleven cases of MCTD and ANCA vasculitis have been reported to date, with only two cases with anti-PR3-ANCA association, and only one vasculitis."

According to the news editors, the research concluded: "The seven other cases reported in the literature presented with an association of MCTD and microscopic polyangiitis which appears to be a more frequent presentation than MCTD associated with GPA."

For more information on this research see: Clinical association of mixed connective tissue disease and granulomatosis with polyangiitis: a case report and systematic screening of anti-U1RNP and anti-PR3 auto-antibody double positivity in ten European hospitals. *Immunologic Research*, 2016;64(5-6):1243-1246. *Immunologic Research* can be contacted at: Humana Press Inc, 999 Riverview Drive Suite 208, Totowa, NJ 07512, USA. Researchers from University of Munich Describe Findings in Cushing Syndrome (Pasireotide can induce sustained decreases in urinary cortisol and provide clinical benefit in patients with Cushing's disease: results from an open-ended, open-label ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Adrenal Gland Diseases and Conditions - Cushing Syndrome have been published. According to news reporting from Munich, Germany, by NewsRx journalists, research stated, "Report the efficacy and safety of pasireotide sc in patients with Cushing's disease during an open-ended, open-label extension to a randomized, double-blind, 12-month, Phase III study. 162 patients entered the core study. 58 patients who had mean UFC (<=) ULN at month 12 or were benefiting clinically from pasireotide entered the extension."

The news correspondents obtained a quote from the research from the University of Munich, "Patients received the same dose of pasireotide as at the end of the core study (300-1,200 mg bid). Dose titration was permitted according to efficacy or drug-related adverse events. 40 patients completed 24 months' treatment. Of the patients who entered the extension, 50.0% (29/58) and 34.5% (20/58) had controlled UFC (UFC (<=) ULN) at months 12 and 24, respectively. The mean percentage decrease in UFC was 57.3% (95% CI 40.7-73.9; n=52) and 62.1% (50.8-73.5; n=33) after 12 and 24 months' treatment, respectively. Improvements in clinical signs of Cushing's disease were sustained up to month 24. The most frequent drug-related adverse events in patients who received (>=)1 dose of pasireotide (n=162) from core baseline until the 24-month cut-off were diarrhea (55.6%), nausea (48.1%), hyperglycemia (38.9%), and cholelithiasis (31.5%). No new safety issues were identified during the extension. Reductions in mean UFC and improvements in clinical signs of Cushing's disease were maintained over 24 months of pasireotide treatment. The safety profile of pasireotide is typical for a somatostatin analogue, except for the frequency and degree of hyperglycemia; patients should be monitored for changes in glucose homeostasis."

According to the news reporters, the research concluded: "Pasireotide represents the first approved pituitary-targeted treatment for patients with Cushing's disease."

For more information on this research see: Pasireotide can induce sustained decreases in urinary cortisol and provide clinical benefit in patients with Cushing's disease: results from an open-ended, open-label extension trial. Pituitary, 2015;18(5):604-12. Pituitary can be contacted at: Springer, 233 Spring Street, New York, NY 10013, USA. (Springer - www.springer.com; Pituitary - www.springerlink.com/content/1386-341x/)

Researchers from University of Naples Discuss Findings in Electrolytes (Diseases associated with electrolyte imbalance in the ED: age-related differences)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Electrolytes have been published. According to news reporting out of Naples, Italy, by NewsRx editors, research stated, "The objective of the study is to investigate the prevalence of electrolyte imbalance (EI) in the emergency department (ED) with systemic diseases in different decades of life. We enrolled patients admitted to the ED."

Our news journalists obtained a quote from the research from the University of Naples, "The population study included 7941 patients, subdivided in 3 groups: young group (Y), middle-aged group (MA), and elderly group (E). We observed EI in 13.7% of the whole population. Hyponatremia (hNa\(^+\)) is the most frequent EI (44%) followed by hypokalemia (hK\(^+\)) (39%), hyperkalemia (HK\(^+\)) (13%), and hypernatremia (HNa\(^+\)) (4.4%). In the Y group, the EI occurred in 7.1% of all patients (P<.05 vs MA and E), whereas in the MA group, they were shown in 11.5% of patients and in the E group in 22% of all patients group (P < .05 vs MA and Y). In the Y group, gastrointestinal diseases are the most frequently associated disease (24.6%; P< .05 vs MA and E). In the MA group, the most frequently associated disease was a current cardiovascular disease (29.7%; P< .05 vs Y and E). In the E group, the frequently associated diseases are cardiovascular (22.8%; P< .05 vs Y) and lung diseases (16.7%; P<.05 vs MA and Y). In our study, 13.7% of all patients showed an EI, and only 2% of cases were alone without any associated systemic disease. Most EIs are associated to other systemic diseases."

According to the news editors, the research concluded: "The present data also depict different age-related and disease-associated prevalence patterns of EI, thus highlighting a complex clinical scenario."

Our news journalists report that additional information may be obtained by
Researchers from University of New Hampshire Report Details of New Studies and Findings in the Area of Infectious Diseases (Microbial Genomics of Ancient Plagues and Outbreaks)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Infectious Diseases have been published. According to news reporting originating in Durham, New Hampshire, by NewsRx journalists, research stated, "The recent use of next-generation sequencing methods to investigate historical disease outbreaks has provided us with an unprecedented ability to address important and long-standing questions in epidemiology, pathogen evolution, and human history."

The news reporters obtained a quote from the research from the University of New Hampshire, "In this review, we present major findings that illustrate how microbial genomics has provided new insights into the nature and etiology of infectious diseases of historical importance, such as plague, tuberculosis, and leprosy. Sequenced isolates collected from archaeological remains also provide evidence for the timing of historical evolutionary events as well as geographic spread of these pathogens."

According to the news reporters, the research concluded: "Elucidating the genomic basis of virulence in historical diseases can provide relevant information on how we can effectively understand the emergence and re-emergence of infectious diseases today and in the future."

Our news correspondents report that additional information may be obtained by contacting C.P. Andam, University of New Hampshire, Dept. of Mol Cellular & Biomed Sci, Durham, NH 03824, United States. Additional authors for this research include C.J. Worby, Q.Z. Chang and M.G. Campana.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1016/j.tim.2016.08.004. This DOI is a link to an online electronic document that is either free or for purchase.

Researchers from University of Nice Sophia-Antipolis Report New Studies and Findings in the Area of Vitamin A Deficiency (Oral tolerance is inefficient in neonatal mice due to a physiological vitamin A deficiency)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Nutritional and Metabolic Diseases and Conditions - Vitamin A Deficiency. According to news reporting originating in Nice, France, by NewsRx journalists, research stated, "Increased risk of allergy during early life indicates deficient immune regulation in this period of life. To date, the cause for inefficient neonatal immune regulation has never been elucidated."

The news reporters obtained a quote from the research from the University of Nice Sophia-Antipolis, "We aimed to define the ontogeny of oral tolerance and to identify necessary conditions specific for this stage of life. Ovalbumin (OVA) was administered orally to mice through breast milk and efficiency of systemic tolerance to OVA was assessed in adulthood using a model of allergic airway inflammation. Oral tolerance induction was fully efficient starting third week of life. Inefficiency in neonates was a consequence of abnormal antigen transfer across the gut barrier and retinaldehyde dehydrogenase expression by mesenteric lymph node CD103(+) neonatal dendritic cells, resulting in inefficient T-cell activation. Neonates' serum retinol levels were three times lower than in adult mice, and vitamin A supplementation was sufficient to rescue neonatal defects and allow tolerance induction from birth. The establishment of oral tolerance required the differentiation of Th1 lymphocytes in both vitamin A-supplemented neonates and 3-week-old unsupplemented mice."

According to the news reporters, the research concluded: "This knowledge should guide the design of interventions for allergy prevention that are adapted to the neonatal stage of life such as vitamin A supplementation."

For more information on this research see: Oral tolerance is inefficient in neonatal mice due to a physiological vitamin A deficiency. *Mucosal Immunology*, 2015;9(2):479-91. *Mucosal Immunology* can be contacted at: Nature Publishing Group, 345 Park Avenue South, New York, NY 10010-1707, USA. Researchers from University of Niigata Detail Findings in Chemotherapy (Structural and Mutagenic Analysis of Metallo-beta-Lactamase IMP-18)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Drugs and Therapies - Chemotherapy have been published. According to news reporting from Niigata, Japan, by NewsRx journalists, research stated, "IMP-type metallo-beta-lactamases (MBLs) are exogenous zinc metalloenzymes that hydrolyze a broad range of beta-lactams, including carbapenems. Here we report the crystal structure of IMP-18, an MBL cloned from Pseudomonas aeruginosa, at 2.0-angstrom resolution."

The news correspondents obtained a quote from the research from the University of Niigata, "The overall structure of IMP-18 resembles that of IMP-1, with an alpha beta/beta alpha 'folded sandwich' configuration, but the loop that covers the active site has a distinct conformation. The relationship between IMP-18's loop conformation and its kinetic properties was investigated by replacing the amino acid residues that can affect the loop conformation (Lys44, Thr50, and Ile69) in IMP-18 with those occupying the corresponding positions in the well-described enzyme IMP-1. The replacement of Thr50 with Pro considerably modified IMP-18's kinetic properties, specifically those pertaining to meropenem, with the k(cat)/K-m value increased by an order of magnitude."

According to the news reporters, the research concluded: "The results indicate that this is a key residue that defines the kinetic properties of IMP-type beta-lactamases."

Our news journalists report that additional information may be obtained by contacting A. Shimizu-Ibuka, Niigata University of Pharmacy & Applied Life Sciences, Fac Appl Life Sci, Akiha Ku, Niigata, Japan. Additional authors for this research include H. Nonomura, Y. Ishii, N.D. Hanson and A. Shimizu-Ibuka.

Researchers from University of Niigata Detail Findings in RNA-Directed DNA Polymerase (A Combination of delta-Tocotrienol and Ferulic Acid Synergistically Inhibits Telomerase Activity in DLD-1 Human Colorectal Adenocarcinoma Cells)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Enzymes and Coenzymes - RNA-Directed DNA Polymerase. According to news reporting originating in Niigata, Japan, by NewsRx journalists, research stated, "Rice bran is a rich source of functional compounds, including tocotrienol (T3) and ferulic acid (FA). We previously investigated the anti-cancer properties of T3, and reported on the potent inhibitory effects of delta-T3 on angiogenesis and telomerase activity."

The news reporters obtained a quote from the research from the University of Niigata, "In this study, we examined the synergistic suppressive effects of the combination of delta-T3 and FA on telomerase activity in DLD-1 human colorectal adenocarcinoma cells. Co-treatment with delta-T3 and FA significantly decreased cellular telomerase activity compared to treatment with delta-T3 alone, whereas FA alone had no inhibitory effect. Co-treatment with delta-T3 and FA also synergistically down-regulated the expression of human telomerase reverse transcriptase (hTERT), the catalytic subunit of telomerase, indicating that the enzymatic activity of telomerase is controlled at the transcriptional level. FA significantly increased the intracellular concentration of delta-T3, suggesting that FA improved the bioavailability of delta-T3 on telomerase."

According to the news reporters, the research concluded: "FA may be a promising candidate for augmenting the anti-cancer activity of delta-T3."

For more information on this research see: A Combination of delta-Tocotrienol and Ferulic Acid Synergistically Inhibits Telomerase Activity in DLD-1 Human Colorectal Adenocarcinoma Cells. *Journal of Nutritional Science and Vitaminology*, 2016;62(5):281-287. *Journal of Nutritional Science and Vitaminology* can be contacted at: Center Academic Publ Japan, 2-4-16 Yayoi, Bunkyo-Ku, Tokyo, 113-0032, Japan.

Researchers from University of North Carolina Describe Findings in Antiretrovirals (Time Preferences Predict Mortality among HIV-Infected Adults Receiving Antiretroviral Therapy in Kenya)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Drugs and Therapies - Antiretrovirals. According to news reporting from Chapel Hill, North Carolina, by NewsRx journalists, research stated, "Identifying characteristics of HIV-infected adults likely to have poor treatment outcomes can be useful for targeting interventions efficiently. Research in economics and psychology suggests that individuals' intertemporal time preferences, which indicate the extent to which they trade-off immediate vs. future cost and benefits, can influence various health behaviors."

The news correspondents obtained a quote from the research from the University of North Carolina, "While there is empirical support for the association between time preferences and various non-HIV health behaviors and outcomes, the extent to which time preferences predict outcomes of those receiving antiretroviral therapy (ART) has not been examined previously. HIV-infected adults initiating ART were enrolled at a health facility in Kenya. Participants' time preferences were measured at enrollment and used to classify them as having either a low or high discount rate for future benefits. At 48 weeks, we assessed mortality and ART adherence, as measured by Medication Event Monitoring System (MEMS). Logistic regression models adjusting for socio-economic characteristics and risk factors were used to determine the association between time preferences and mortality as well as MEMS adherence (>=90%). Overall, 44% (96/220) of participants were classified as having high discount rates. Participants with high discount rates had significantly higher 48-week mortality than participants with low discount rates (9.3% vs. 3.1%; adjusted odds ratio 3.84; 95% CI 1.03, 14.50). MEMS adherence (>=90%) was similar for participants with high vs. low discount rates (42.3% vs. 49.6%, AOR 0.70; 95% CI 0.40, 1.25). High discount rates were associated with significantly higher risk of mortality among HIV-infected patients initiating ART. Greater use of time preference measures may improve identification of patients at risk of poor clinical outcomes."

According to the news reporters, the research concluded: "More research is needed to further identify mechanisms of action and also to build upon and test the generalizability of this finding."

For more information on this research see: Time Preferences Predict Mortality among HIV-Infected Adults Receiving Antiretroviral Therapy in Kenya. Plos One, 2015;10 (12):e0145245. (Public Library of Science - www.plos.org; Plos One - www.plosone.org)

Researchers from University of North Carolina Detail New Studies and Findings in the Area of Antiretrovirals (Neurocognition with maraviroc compared with tenofovir in HIV)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Drugs and Therapies - Antiretrovirals. According to news originating from Chapel Hill, North Carolina, by NewsRx correspondents, research stated, "The objective was to determine whether maraviroc (MVC) has unique neurocognitive benefits in the context of initial antiretroviral therapy (ART). Randomized, double-blind, placebo-controlled, 48-week trial."

Our news journalists obtained a quote from the research from the University of North Carolina, "Participants were enrolled in US AIDS Clinical Trials Group clinical trial sites. Total 262 ART-naive, chemokine coreceptor 5 tropic HIV, and HIV RNA greater than 1000 copies/ml participants were randomized, 230 participants completed the study. Participants received MVC 150 mg or tenofovir disoproxil fumarate (TDF) 300mg on a background of ritonavir-boosted darunavir and emtricitabine. Main outcome measure(s): The neuropsychological battery of 15 tests done at baseline, week 24 and week 48 assessed seven domains, and were standardized into z-scores then converted into deficit scores and a global deficit score. The 48-week changes from baseline in the neuropsychological scores and the global deficit score were compared by Wilcoxon or Kruskal-Wallis test between arms, and among baseline impairment groups [classified as normal, mild (2 deficit scores >= 1) and moderate (2 deficit scores >= 2)]. It was hypothesized that the MVC arm would have improved neuropsychological performance over TDF. In this double-blind, randomized, placebo-controlled trial, there were no differences in neuropsychological performance between MVC and TDF. Those with moderate neuropsychological impairment at baseline experienced greater ART-mediated neuropsychological improvement than those with mild or no neuropsychological impairment."

According to the news editors, the research concluded: "Improvement in neurocognitive functioning was greater with more baseline impairment but was comparable with MVC or TDF."

For more information on this research see: Neurocognition with maraviroc compared with tenofovir in HIV. *Aids*, 2016;30(15):2315-2321. *Aids* can be contacted at: Lippincott Williams & Wilkins, Two Commerce Sq, 2001 Market St, Philadelphia, PA 19103, USA. Researchers from University of Nottingham Describe Findings in Congenital Heart Defects (Cardiac troponin T is necessary for normal development in the embryonic chick heart)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Congenital Diseases and Conditions - Congenital Heart Defects is the subject of a report. According to news reporting out of Nottingham, United Kingdom, by NewsRx editors, research stated, "The heart is the first functioning organ to develop during embryogenesis. The formation of the heart is a tightly regulated and complex process, and alterations to its development can result in congenital heart defects."

Our news journalists obtained a quote from the research from the University of Nottingham, "Mutations in sarcomeric proteins, such as alpha myosin heavy chain and cardiac alpha actin, have now been associated with congenital heart defects in humans, often with atrial septal defects. However, cardiac troponin T (cTNT encoded by gene TNNT2) has not. Using gene-specific antisense oligonucleotides, we have investigated the role of cTNT in chick cardiogenesis. TNNT2 is expressed throughout heart development and in the postnatal heart. TNNT2-morpholino treatment resulted in abnormal atrial septal growth and a reduction in the number of trabeculae in the developing primitive ventricular chamber. External analysis revealed the development of diverticula from the ventricular myocardial wall which showed no evidence of fibrosis and still retained a myocardial phenotype. Sarcomeric assembly appeared normal in these treated hearts. In humans, congenital ventricular diverticulum is a rare condition, which has not yet been genetically associated. However, abnormal haemodynamics is known to cause structural defects in the heart. Further, structural defects, including atrial septal defects and congenital diverticula, have previously been associated with conduction anomalies. Therefore, to provide mechanistic insights into the effect that cTNT knockdown has on the developing heart, quantitative PCR was performed to determine the expression of the shear stress responsive gene NOS3 and the conduction gene TBX3. Both genes were differentially expressed compared to controls. Therefore, a reduction in cTNT in the developing heart results in abnormal atrial septal formation and aberrant ventricular morphogenesis. We hypothesize that alterations to the haemodynamics, indicated by differential NOS3 expression, causes these abnormalities in growth in cTNT knockdown hearts. In addition, the muscular diverticula reported here suggest a novel role for mutations of structural sarcomeric proteins in the pathogenesis of congenital cardiac diverticula."

According to the news editors, the research concluded: "From these studies, we suggest TNNT2 is a gene worthy of screening for those with a congenital heart defect, particularly atrial septal defects and ventricular diverticula."

For more information on this research see: Cardiac troponin T is necessary for normal development in the embryonic chick heart. Journal of Anatomy, 2016;229(3):436-449.
Researchers from University of Occupational and Environmental Health Describe Findings in Hypertrophic Cardiomyopathy (Cumulative Burden of Myocardial Dysfunction in Cardiac Amyloidosis Assessed Using Four-Chamber Cardiac Strain)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Heart Disorders and Diseases - Hypertrophic Cardiomyopathy are presented in a new report. According to news reporting out of Kitakyushu, Japan, by NewsRx editors, research stated, "The aim of this study was to test the hypothesis that prognosis in patients with cardiac amyloidosis is closely coupled with amyloid burden in all four cardiac chambers. The goal was to evaluate longitudinal strain (LS) in each cardiac chamber and to determine whether LS in specific cardiac chambers is preferentially associated with prognosis over conventional two-dimensional echocardiographic parameters in patients with cardiac amyloidosis."

Our news journalists obtained a quote from the research from the University of Occupational and Environmental Health, "Patients with two phenotypes of left ventricular (LV) hypertrophy (cardiac amyloidosis in 55 patients and nonobstructive hypertrophic cardiomyopathy in 40 patients) and 55 healthy subjects were retrospectively enrolled for the simultaneous assessment of LS of all four cardiac chambers in the apical four-chamber view. Patients with cardiac amyloidosis were followed up to record major adverse cardiovascular events, including cardiac death, heart transplantation, nonfatal myocardial infarction, ventricular tachyarrhythmia, and exacerbation of heart failure requiring hospitalization. LS in each chamber was significantly depressed in patients with both LV hypertrophy phenotypes compared with healthy subjects. Right atrial LS was significantly lower in patients with cardiac amyloidosis than those with nonobstructive hypertrophic cardiomyopathy after adjusting for LV ejection fraction and LV mass index. During a median follow-up period of 10 months, major adverse cardiovascular events developed in 22 patients with cardiac amyloidosis. Four-chamber LS were significantly associated with major adverse cardiovascular events, with incremental value over traditional echocardiographic parameters."

According to the news editors, the research concluded: "Cardiac amyloidosis
involves all cardiac chambers, and thus, chamber-specific strain analysis may be useful to assess the total cumulative burden of cardiac dysfunction."

Our news journalists report that additional information may be obtained by contacting M. Takeuchi, University of Occupational & Environmental Health, Sch Med, Dept. of Lab & Transfus Med, Kitakyushu, Fukuoka 8078555, Japan. Additional authors for this research include M. Obokata, Y. Nagata, T. Ishizu, K. Addetia, K. Aonuma, M. Kurabayashi, R.M. Lang, M. Takeuchi and Y. Otsuji.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1016/j.echo.2016.07.017. This DOI is a link to an online electronic document that is either free or for purchase.

**Oncology - Cervical Cancer**

Researchers from University of Oklahoma Detail New Studies and Findings in the Area of Cervical Cancer (Is age a prognostic biomarker for survival among women with locally advanced cervical cancer treated with chemoradiation? An NRG ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Oncology - Cervical Cancer are presented in a new report. According to news reporting originating from Oklahoma City, Oklahoma, by NewsRx correspondents, research stated, "To determine the effect of age on completion of and toxicities following treatment of local regionally advanced cervical cancer (LACC) on Gynecologic Oncology Group (GOG) Phase I-HI trials. An ancillary data analysis of GOG protocols 113, 120, 165, 219 data was performed."

Our news editors obtained a quote from the research from the University of Oklahoma, "Wilcoxon, Pearson, and Kruskal-Wallis tests were used for univariate and multivariate analysis. Log rank tests were used to compare survival lengths. One-thousand-three-hundred-nineteen women were included; 60.7% were Caucasian, 15% were age 60-70 years and an additional 5% were >70; 87% had squamous histology, 55% had stage IIB disease and 34% had IIB disease. Performance status declined with age (p = 0.006). Histology and tumor stage did not significantly differ. Number of cycles of chemotherapy received, radiation treatment time, nor dose modifications varied with age. Notably, radiation protocol deviations..."
and failure to complete brachytherapy (BT) did increase with age (p = 0.022 and p < 0.001 respectively). Only all grade lymphatic (p = 0.006) and grade >= 3 cardiovascular toxicities (p = 0.019) were found to vary with age. A 2% increase in the risk of death for every year increase > 50 for all-cause mortality (HR 1.02; 95% CI, 1.01-1.04) was found, but no association between age and disease specific mortality was found. This represents a large analysis of patients treated for LACC with chemo/radiation, approximately 20% of whom were >60 years of age. Older patients, had higher rates of incomplete brachytherapy which is not explained by collected toxicity data."

According to the news editors, the research concluded: "Age did not adversely impact completion of chemotherapy and radiation or toxicities."

The news editors report that additional information may be obtained by contacting K.N. Moore, University of Oklahoma, Stephenson Oklahoma Canc Center, Div Gynecol Oncol, Oklahoma City, OK 73121, United States. Additional authors for this research include J.J. Java, K.N. Slaughter, P.G. Rose, R. Lanciano, P.A. DiSilvestro, J.T. Thigpen, Y.C. Lee, K.S. Tewari, J. Chino, S.M. Seward, D.S. Miller, R. Salani, D.H. Moore and F.B. Stehman.

**Adolescence**

**Researchers from University of Oslo Report Details of New Studies and Findings in the Area of Adolescence (Associations Between Sibling Relationship Quality and Friendship Quality in Early Adolescence: Looking at the Case of Twins)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Adolescence have been presented. According to news reporting originating in Oslo, Norway, by NewsRx journalists, research stated, "Bidirectional pathways between twin relationship quality and friendship quality were investigated in a large longitudinal twin cohort. We examined negative and positive relationship features in 313 monozygotic (MZ) twins and 238 same-sex dizygotic (DZ) twins from ages 13 to 14 years, using latent structural modeling."

The news reporters obtained a quote from the research from the University of Oslo, "Results showed stronger stability of the twin relationship quality compared to friendship..."
quality. Positive features in the sibling relationship were associated with increased positive features in the relationship with the best friend a year later. In contrast, no significant association between negative sibling relationship features and change in negative friendship quality features was found."

According to the news reporters, the research concluded: "These findings speak to the important role of the sibling relationship in the development of good quality friendship relations in twins."

For more information on this research see: Associations Between Sibling Relationship Quality and Friendship Quality in Early Adolescence: Looking at the Case of Twins. Twin Research and Human Genetics, 2016;19(2):125-35. (Cambridge University Press - www.cambridge.org; Twin Research and Human Genetics - journals.cambridge.org/action/displayJournal?jid=THG)

Parotid Diseases and Conditions - Mumps

Researchers from University of Ottawa Report Details of New Studies and Findings in the Area of Mumps (Mechanisms of temperature sensitivity of attenuated Urabe mumps virus)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Parotid Diseases and Conditions - Mumps. According to news originating from Ottawa, Canada, by NewsRx correspondents, research stated, "Temperature sensitivity is a phenotype often associated with attenuation of viruses. Previously, we purified several mumps variants from an incompletely attenuated Urabe strain live attenuated vaccine."

Financial supporters for this research include National Sciences and Engineering Research Council of Canada, Erica Langley and Daniel Ngo for technical support with sequencing and western blots.

Our news journalists obtained a quote from the research from the University of Ottawa, "Here we characterize one isolate that is sensitive to growth at high temperature. This virus was attenuated in a small animal model of mumps virulence, and we identified unique coding substitutions in the hemagglutinin-neuraminidase (HN), the viral polymerase (L) gene, and a non-coding substitution close to the anti-genome promoter sequences. At the non-permissive temperature, transcription of viral mRNAs and production of the replication intermediate were reduced compared to events at the permissive temperature and to a non-ts virulent Urabe virus. As well, synthesis of viral proteins was also reduced at the higher
According to the news editors, the research concluded: "While the actual sequence substitutions in the virus were unique, the pattern of substitutions in HN, L and genome end sequences is similar to another attenuated Urabe virus previously described by us."

For more information on this research see: Mechanisms of temperature sensitivity of attenuated Urabe mumps virus. *Virus Research*, 2017;227():104-109. *Virus Research* can be contacted at: Elsevier Science Bv, PO Box 211, 1000 Ae Amsterdam, Netherlands. (Elsevier - www.elsevier.com; Virus Research - www.journals.elsevier.com/virus-research/)

The news correspondents report that additional information may be obtained from S.C.B. Schinkel, University of Ottawa, Dept. of Biochem Microbiol & Immunol, Ottawa, ON K1H 8M5, Canada. Additional authors for this research include S. Rubin and K.E. Wright.

**Drugs and Therapies - Glucagon Therapy**

**Researchers from University of Palermo Report Findings in Glucagon Therapy (Influence of glucagon-like peptide 2 on energy homeostasis)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Drugs and Therapies - Glucagon Therapy have been published. According to news reporting from Palermo, Italy, by NewsRx journalists, research stated, "Glucagon like peptide-2 (GLP-2) is a gastrointestinal hormone released from enteroendocrine L-type cells together with glucagon like peptide-1 in response to dietary nutrients. GLP-2 acts through a specific receptor, the GLP-2 receptor, mainly located in the gut and in the brain."

The news correspondents obtained a quote from the research from the University of Palermo, "Classically, GLP-2 is considered a trophic hormone involved in the maintenance of intestinal epithelial morphology and function. This role has been targeted for therapies promoting repair and adaptive growth of the intestinal mucosa. Recently, GLP-2 has been shown to exert beneficial effects on glucose metabolism specially in conditions related to increased uptake of energy, such as obesity. Several actions of GLP-2 are related to a positive energy balance: GLP-2 increases not only the absorptive surface, but also expression and activity of epithelial brush-border nutrient transporters and digestive enzymes, intestinal blood flow, postprandial chylomicron secretion and it inhibits gastrointestinal motility, providing the opportunity to increase absorption of nutrients. Other actions, including anorexigenic effects, appear in opposition to the energy intake. In this review, we discuss the GLP-2 functions related to energy homeostasis."

According to the news reporters, the research concluded: "GLP-2 could be
considered an hormone causing positive energy balance, which, however has the role to mitigate the metabolic dysfunctions associated with hyper-adiposity."

For more information on this research see: Influence of glucagon-like peptide 2 on energy homeostasis. Peptides, 2016;86():1-5. Peptides can be contacted at: Elsevier Science Inc, 360 Park Ave South, New York, NY 10010-1710, USA. (Elsevier - www.elsevier.com; Peptides - www.journals.elsevier.com/peptides/)

Our news journalists report that additional information may be obtained by contacting F. Mule, University of Palermo, Dipartimento Sci & Tecnol Biol Chim & Farmaceut S, I-90128 Palermo, Italy. Additional authors for this research include A. Amato and F. Mule.

Oncology

Researchers from University of Palermo Report on Findings in Oncology (What links BRAF to the heart function? New insights from the cardiotoxicity of BRAF inhibitors in cancer treatment)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Oncology. According to news reporting out of Palermo, Italy, by NewsRx editors, research stated, "The RAS-related signalling cascade has a fundamental role in cell. It activates differentiation and survival."

Our news journalists obtained a quote from the research from the University of Palermo, "It is particularly important one of its molecules, B-RAF. B-RAF has been a central point for research, especially in melanoma. Indeed, it lacked effective therapeutic weapons since the early years of its study. Molecules targeting B-RAF have been developed. Nowadays, two classes of molecules are approved by FDA. Multi-target molecules, such as Sorafenib and Regorafenib, and selective molecules, such as Vemurafenib and Dabrafenib. Many other molecules are still under investigation. Most of them are studied in phase 1 trials. Clinical studies correlate B-RAF inhibitors and QT prolongation. Though this cardiovascular side effect is not common using these drugs, it must be noticed early and recognize its signals. Indeed, Oncologists and Cardiologists should work in cooperation to prevent lethal events, such as fatal arrhythmias or sudden cardiac death."

According to the news editors, the research concluded: "These events could originate from an uncontrolled QT prolongation."

For more information on this research see: What links BRAF to the heart function? New insights from the cardiotoxicity of BRAF inhibitors in cancer treatment. Oncotarget, 2015;6(34):35589-601.

Researchers from University of Paris Discuss Findings in Arsenic (Exposure assessment of arsenic speciation in different rice types depending on the cooking mode)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Arsenic have been published. According to news reporting originating from Maisons Alfort, France, by NewsRx correspondents, research stated, "Total (Ass), inorganic arsenic (As-i=As(III)+As(V)) and dimethylarsonic acid (DMA) were determined in 37 commercial rice samples collected in France. As-t was measured by inductively coupled plasma-mass spectrometry (ICP-MS) whereas anion-exchange chromatography - ICP-MS was used for As; and DMA determination."

Financial support for this research came from French Ministry of Food, Agriculture and Fisheries.

Our news editors obtained a quote from the research from the University of Paris, "Ast in raw rice varied from 0.041 to 0.535 mg kg(-1) whereas As; varied from 0.025 mg kg(-1) (polished Basmati rice) up to 0.471 mg kg(-1) (organic rice duo). The daily intake and associated health risk for different population groups as a function of age and gender was also assessed. The intake varied between 0.002 and 0.184 µg kg(-1) body weight for Ast and 0.002 and 0.153 µg kg(-1) body weight for As;, which do not pose a chronic toxicity risk. Organic wholegrain rice may entail a risk for children in the case of sole consumption at the expense of polished rice. The impact of rice cooking/boiling in terms of the overall toxicological risk related to As species was also investigated."

According to the news editors, the research concluded: "Pre-rinsing and boiling the raw rice by using an excess of water is the most efficient mode to obtain a significant As; removal and further reduction of the toxicological risk for children, particularly for white rice varieties."

For more information on this research see: Exposure assessment of arsenic speciation in different rice types depending on the cooking mode. *Journal of Food Composition and Analysis*, 2016;54():37-47. *Journal of Food Composition and Analysis* can be contacted at: Academic Press Inc Elsevier Science, 525 B St, Ste 1900, San Diego, CA 92101-4495, USA. (Elsevier - www.elsevier.com; Journal of Food Composition and Analysis - www.journals.elsevier.com/journal-of-food-composition-and-analysis/)

The news editors report that additional information may be obtained by contacting T.
Researchers from University of Paris-Sud Report Recent Findings in Dynamic Light Scattering (Size of monodispersed nanomaterials evaluated by dynamic light scattering: Protocol validated for measurements of 60 and 203 nm diameter nanomaterials ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Dynamic Light Scattering is the subject of a report. According to news reporting originating from Chatenay Malabry, France, by NewsRx correspondents, research stated, "In vivo fate of nanomaterials is influenced by the particle size among other parameters. Thus, Health Agencies have identified the size of nanomaterial as an essential physicochemical property to characterize."

Our news editors obtained a quote from the research from the University of Paris-Sud, "This parameter can be explored by dynamic light scattering (DLS) that is described in the ISO standard 22412: 2008(E) and is one of the methods recognized by Health Agencies. However, no protocol of DLS size measurement has been validated over a large range of size so far. In this work, we propose an extension of validation of a protocol of size measurement by DLS previously validated with certified reference materials (CRM) at 60 and 203 nm. The present work reports robustness, precision and trueness of this protocol that were investigated using CRM at 100 and 400 nm. The protocol was robust, accurate and consistent with the ISO standard over the whole range of size that were considered. Expanded uncertainties were 4.4 and 3.6% for CRM at 100 and 400 nm respectively indicating the reliability of the protocol."

According to the news editors, the research concluded: "The range of application of the protocol previously applied to the size measurement of liposomes and polymer nanoparticles was extended to inorganic nanomaterial including silica nanoparticles."

For more information on this research see: Size of monodispersed nanomaterials evaluated by dynamic light scattering: Protocol validated for measurements of 60 and 203 nm diameter nanomaterials is now extended to 100 and 400 nm. *International Journal of Pharmaceutics*, 2016;515(1-2):245-253. *International Journal of Pharmaceutics* can be contacted at: Elsevier Science Bv, PO Box 211, 1000 Ae Amsterdam, Netherlands. (Elsevier - www.elsevier.com; International Journal of Pharmaceutics - www.journals.elsevier.com/international-journal-of-pharmaceutics/)

The news editors report that additional information may be obtained by contacting C. Vauthier, Univ Paris Saclay, Univ Paris Sud, CNRS, Inst Galien Paris Sud, Chatenay Malabry, France. Additional authors for this research include J. Botton, C. Merlet, H. Hillaireau, F.X. Legrand, G. Barratt and C. Vauthier.
Researchers from University of Parma Detail Findings in Oxidoreductases (Catalysis and Structure of Zebrafish Urate Oxidase Provide Insights into the Origin of Hyperuricemia in Hominoids)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Enzymes and Coenzymes - Oxidoreductases. According to news originating from Parma, Italy, by NewsRx correspondents, research stated, "Urate oxidase (Uox) catalyses the first reaction of oxidative uricolysis, a three-step enzymatic pathway that allows some animals to eliminate purine nitrogen through a water-soluble compound. Inactivation of the pathway in hominoids leads to elevated levels of sparingly soluble urate and puts humans at risk of hyperuricemia and gout."

Our news journalists obtained a quote from the research from the University of Parma, "The uricolytic activities lost during evolution can be replaced by enzyme therapy. Here we report on the functional and structural characterization of Uox from zebrafish and the effects on the enzyme of the missense mutation (F216S) that preceded Uox pseudogenization in hominoids. Using a kinetic assay based on the enzymatic suppression of the spectroscopic interference of the Uox reaction product, we found that the F216S mutant has the same turnover number of the wild-type enzyme but a much-reduced affinity for the urate substrate and xanthine inhibitor. Our results indicate that the last functioning Uox in hominoid evolution had an increased Michaelis constant, possibly near to upper end of the normal range of urate in the human serum (similar to 300 μM)."

According to the news editors, the research concluded: "Changes in the renal handling of urate during primate evolution can explain the genetic modification of uricolytic activities in the hominoid lineage without the need of assuming fixation of deleterious mutations."

The news correspondents report that additional information may be obtained from R. Percudani, University of Parma, Dept. of Life Sci, I-43124 Parma, Italy. Additional authors for this research include A. Liuzzi, B. Fermi, R. Corsini, C. Folli, V. Speranzini, F. Gandolfi, S. Bettati, L. Ronda, L. Cendron, R. Berni, G. Zanotti and R. Percudani.

Researchers from University of Pennsylvania Describe Findings in Obesity (Primary Care Interventions to Reduce Childhood Obesity in Latino Families)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Nutritional and Metabolic Diseases and Conditions - Obesity. According to news reporting from Philadelphia, Pennsylvania, by NewsRx editors, the research stated, "Increasing rates of obesity in Latino children call for culturally sensitive primary care interventions. Despite recent efforts to address this growing disparity, little is known about cultural variables that influence obesity management programs in Latino children."

The news correspondents obtained a quote from the research from the University of Pennsylvania, "A literature search was conducted using CINHAL, Scopus, PubMed, and PsycINFO to review the state of the science regarding primary care interventions to decrease obesity in Latino children. The author analyzed the effects of several cultural practices on obesity and made recommendations based on their clinical implications for weight reduction management programs. Obesity in Latino children is a multifactorial problem influenced by family behaviors, cultural perceptions of weight and health, traditional dietary norms, and socioeconomic status. Current practice lags behind national obesity management recommendations and is further hindered by a lack of consideration of the roles of key cultural differences in Latino families. It is imperative to recognize the importance of family preferences and culture when developing weight reduction programs so as to foster long-term behavior changes."

According to the news reporters, the research concluded: "More research assessing the efficacy of culturally competent interventions is necessary to guide national efforts to address this increasing disparity."

Our news journalists report that additional information may be obtained by contacting G. Gonzalez, University of Pennsylvania, Sch Nursing, Dept. of Pediat Primary Care, Philadelphia, PA 19104, United States.

Researchers from University of Pennsylvania Report Findings in Pulmonary Embolism (Risk of pulmonary embolism after a prior negative CT pulmonary angiogram)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Lung Diseases and Conditions - Pulmonary Embolism are discussed in a new report. According to news reporting originating from Philadelphia, Pennsylvania, by NewsRx correspondents, research stated, "With increasing utilization of computed tomography pulmonary angiography (CTPA) for the diagnosis of pulmonary embolism (PE), many patients undergo repeat CTs. The aim of this study is to identify the rate of positive subsequent CTPAs after an initial negative CTPA and whether there is a risk-free period after a negative CTPA."

Our news editors obtained a quote from the research from the University of Pennsylvania, "We evaluated 318 patients with at least 1 subsequent CTPA after an initial negative CTPA, with 786 total CTPAs. We also evaluated a control group of 200 unselected CTPAs. The positive rate in the repeat group was 7% at the first repeat CTPA and 10% per-patient within 1000 days. The positive rate in the control group was 9%(P-not significant). No risk-free period was seen, with a positive rate of 5% within 2 weeks after a negative CTPA. The number of prior negative CTPAs showed a trend towards decreasing rate of the subsequent CTPA being positive, but this did not meet statistical significance. There is no risk-free period after an initial negative CTPA, and therefore, patients with clinical suspicion of PE should be rescanned even after a recent negative study. Even patients with multiple negative prior CTPAs have a measurable risk of subsequent PE."

According to the news editors, the research concluded: "Established clinical prediction scoring systems must be used to triage the patients who need CTPAs."

The news editors report that additional information may be obtained by contacting H.I. Litt, University of Pennsylvania, Dept. of Radiol, Perelman Sch Med, Philadelphia, PA 19104, United States.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1016/j.ajem.2016.07.002. This DOI is a link to an online electronic document that is either free or for purchase.

Keywords for this news article include: Philadelphia, Pennsylvania, United States, North and Central America, Respiratory Tract Diseases and Conditions, Cardiovascular Diseases and Conditions, Vascular Diseases and Conditions, Lung Diseases and Conditions, Embolism and Thrombosis, Risk and Prevention, Pulmonary Embolism, University of Pennsylvania.

Researchers from University of Pittsburgh Report Findings in Attention Deficit Hyperactivity Disorders (Gestational weight gain, prepregnancy body mass index and offspring attention-deficit hyperactivity disorder symptoms and behaviour at age 10)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Developmental Diseases and Conditions - Attention Deficit Hyperactivity Disorders. According to news originating from Pittsburgh, Pennsylvania, by NewsRx correspondents, research stated, "To assess offspring attention-deficit hyperactivity disorder (ADHD) symptoms and emotional/behavioural impairments at age 10 years in relation to maternal gestational weight gain (GWG) and prepregnancy body mass index (BMI). Longitudinal birth cohort from Magee-Womens Hospital, Pittsburgh, Pennsylvania (enrolled 1983-86)."

Financial support for this research came from National Institutes of Health.

Our news journalists obtained a quote from the research from the University of Pittsburgh, "Mother-infant dyads (n=511) were followed through pregnancy to 10 years. Self-reported total GWG was converted to gestational-age-standardised z-scores. Multivariable linear and negative binomial regressions were used to estimate effects of GWG and BMI on outcomes. Child ADHD symptoms were assessed with the Conners' Continuous Performance Test. Child behaviour was assessed by parent and teacher ratings on the Child Behaviour Checklist (CBCL) and Teacher Report Form, respectively. The mean (SD) total GWG (kg) was 14.5 (5.9), and 10% of women had a pregravid BMI (>=)30 kg/m. Prepregnancy obesity (BMI of 30 kg/m²) was associated with increased offspring problem behaviours including internalising behaviours (adjusted b 3.3 points, 95% CI 1.7-4.9), externalising behaviours (adjusted b 2.9 points, 95% CI 1.4-4.6), and attention problems (adjusted b 2.3 points, 95% CI 1.1-3.4) on the CBCL, compared with normal weight mothers (BMI of 22 kg/m²). There were nonsignificant trends towards increased offspring impulsivity with low GWG among lean mothers (adjusted incidence rate ratio 1.2, 95% CI 0.9-1.5) and high GWG among overweight mothers (adjusted incidence rate ratio 1.7, 95% CI 0.9-2.8), but additional outcomes did not differ by GWG z-score. Results were not meaningfully different after excluding high-substance users. In a low-income and high-risk sample, we observed a small increase in child behaviour problems among children of obese mothers, which could have an impact on child behaviour in the population."

According to the news editors, the research concluded: "Maternal obesity is associated with a small increase in child behaviour problems."

The news correspondents report that additional information may be obtained from S.J. Pugh, Dept. of Epidemiology, Graduate School of Public Health, University of Pittsburgh, Pittsburgh, PA, United States. Additional authors for this research include J.A. Hutcheon, G.A. Richardson, M.M. Brooks, K.P. Himes, N.L. Day and L.M Bodnar.

Researchers from University of Pittsburgh Report on Findings in Genetic Epidemiology (A Pipeline for Classifying Relationships Using Dense SNP/SNV Data and Putative Pedigree Information)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Genetics - Genetic Epidemiology. According to news reporting originating in Pittsburgh, Pennsylvania, by NewsRx journalists, research stated, "When genome-wide association studies (GWAS) or sequencing studies are performed on family-based datasets, the genotype data can be used to check the structure of putative pedigrees. Even in datasets of putatively unrelated people, close relationships can often be detected using dense single-nucleotide polymorphism/variant (SNP/SNV) data."

Financial support for this research came from COHRA (US) and GENEVA (Guatemala) datasets.

The news reporters obtained a quote from the research from the University of Pittsburgh, "A number of methods for finding relationships using dense genetic data exist, but they all have certain limitations, including that they typically use average genetic sharing, which is only a subset of the available information. Here, we present a set of approaches for classifying relationships in GWAS datasets or large-scale sequencing datasets. We first propose an empirical method for detecting identity by descent segments in close relative pairs using un-phased dense SNP data and demonstrate how that information can assist in building a relationship classifier. We then develop a strategy to take advantage of putative pedigree information to enhance classification accuracy. Our methods are tested and illustrated with two datasets from two distinct populations."

According to the news reporters, the research concluded: "Finally, we propose classification pipelines for checking and identifying relationships in datasets containing a large number of small pedigrees."

Our news correspondents report that additional information may be obtained by contacting Z. Zeng, Dept. of Biostatistics, Graduate School of Public Health, University of Pittsburgh, Pittsburgh, Pennsylvania, United States. Additional authors for this research include D.E. Weeks, W. Chen, N. Mukhopadhyay and E. Feingold.

Researchers from University of Pittsburgh Report on Findings in Type 1 Diabetes Mellitus (Are Regulatory T Cells Defective in Type 1 Diabetes and Can We Fix Them?)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Nutritional and Metabolic Diseases and Conditions - Type 1 Diabetes Mellitus. According to news reporting originating from Pittsburgh, Pennsylvania, by NewsRx correspondents, research stated, "Regulatory T cells (Tregs) are critical regulators of peripheral immune tolerance. Treg insufficiency can lead to autoimmune disorders, including type 1 diabetes (T1D)."

Our news editors obtained a quote from the research from the University of Pittsburgh, "Increasing evidence in mouse models of T1D, as well as other autoimmune disorders, suggests that there are defects in Treg-mediated suppression. Indeed, whereas Treg frequency in the peripheral blood of T1D patients is unaltered, their suppressive abilities are diminished compared with Tregs in healthy controls. Although expression of the transcription factor Foxp3 is a prerequisite for Treg development and function, there are many additional factors that can alter their stability, survival, and function. Much has been learned in other model systems, such as tumors, about the mechanism and pathways that control Treg stability and function."

According to the news editors, the research concluded: "This review poses the question of whether we can use these findings to develop new therapeutic approaches that might boost Treg stability, survival, and/or function in T1D and possibly other autoimmune disorders."

For more information on this research see: Are Regulatory T Cells Defective in Type 1 Diabetes and Can We Fix Them? Journal of Immunology, 2016;197(10):3762-3770.

Researchers from University of Pretoria Describe Findings in Tuberculosis (Antimycobacterial Activity and Low Cytotoxicity of Leaf Extracts of Some African Anacardiaceae Tree Species)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Mycobacterium Infections - Tuberculosis have been published. According to news reporting from Onderstepoort, South Africa, by NewsRx journalists, research stated, "Treatment of tuberculosis (TB) is a challenge because of multidrug-resistant and extremely drug-resistant strains of Mycobacterium tuberculosis. Plant species contain antimicrobial compounds that may lead to new anti-TB drugs."

The news correspondents obtained a quote from the research from the University of Pretoria, "Previous screening of some tree species from the Anacardiaceae family revealed the presence of antimicrobial activity, justifying further investigations. Leaf extracts of 15 Anacardiaceae tree species were screened for antimycobacterial activity using a twofold serial microdilution assay against the pathogenic Mycobacterium bovis and multidrug resistant M. tuberculosis and rapidly growing mycobacteria, Mycobacterium smegmatis, Mycobacterium fortuitum and Mycobacterium aurum. The vaccine strain, M. bovis and an avirulent strain, H37Ra M. tuberculosis, were also used. Cytotoxicity was assessed using a colorimetric assay against Vero kidney, human hepatoma and murine macrophage cells. Four out of 15 crude acetone extracts showed significant antimycobacterial activity with minimum inhibitory concentration varying from 50 to 100 μg/mL. Searsia undulata had the highest activity against most mycobacteria, followed by Protorhus longifolia. M. fortuitum was the strongest predictor of activity against multidrug-resistant TB (correlation coefficient = 0.65). Bioautography against M. aurum and M. fortuitum worked well as indicators of the Rf values of active compounds yielding strong zones of inhibition."

According to the news reporters, the research concluded: "The leaf extracts of S. undulata and P. longifolia had more than ten different antimycobacterial compounds and had low cytotoxicity with LC50 values above 100 μg/mL."

Our news journalists report that additional information may be obtained by contacting P.N. Kabongo-Kayoka, University of Pretoria, Fac Vet Sci, Dept. of Paraclin Sci, Phytomed Programme, ZA-0110 Onderstepoort, South Africa. Additional authors for this research include J.N. Eloff, C.L. Obi and L.J. Mcgaw.

Researchers from University of Queensland Describe Findings in Oral Cancer (Knowledge of oral cancer risk factors amongst high-risk Australians: findings from the LESIONS programme)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Oncology - Oral Cancer. According to news originating from Herston, Australia, by NewsRx correspondents, research stated, "Patient awareness of risk factors associated with cancer has been shown to increase patient presentation for screening and early detection. This study aimed to identify the level of awareness of oral cancer risk factors in a high risk Australian population."

Financial support for this research came from Queensland Government.

Our news journalists obtained a quote from the research from the University of Queensland, "Participants were recruited from the LESIONS programme between April 2012 and April 2014. Demographics were collected via semi-structured interview. A self-administered questionnaire was provided, listing a number of possible oral cancer risk factors. Participants were requested to indicate their level of agreement on a three-point scale. Bivariate and multivariable analysis was performed. A total of 1498 participants took part in the LESIONS programme and were invited to complete the questionnaire. The most common risk factors thought to be associated with oral cancer were smoking (87.5%), poor oral hygiene (67.9%) and family history (61.1%). Only 50.2% of respondents were aware of alcohol consumption as a risk factor. While most participants were aware of the association between smoking and oral cancer, only half were aware of the significant risk alcohol consumption poses. A significant portion of participants also held a number of inaccurate beliefs in relation to oral cancer risk."

According to the news editors, the research concluded: "These findings can benefit both clinicians and public health policy makers in targeting oral cancer education."

The news correspondents report that additional information may be obtained from F. Dost, The University of Queensland Centre for Clinical Research, Herston, Queensland, Australia. Additional authors for this research include L. Do and C.S Farah.

Researchers from University of Rennes Report Recent Findings in Biotheoretics (Recursive Model Identification for the Evaluation of Baroreflex Sensitivity)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Life Science Research - Biotheoretics. According to news reporting out of Rennes, France, by NewsRx editors, research stated, "A method for the recursive identification of physiological models of the cardiovascular baroreflex is proposed and applied to the time-varying analysis of vagal and sympathetic activities."

Financial support for this research came from Canada Research Chair in Neonatal Respiratory Physiology.

Our news journalists obtained a quote from the research from the University of Rennes, "The proposed method was evaluated with data from five newborn lambs, which were acquired during injection of vasodilator and vasoconstrictors and the results show a close match between experimental and simulated signals. The model-based estimation of vagal and sympathetic contributions were consistent with physiological knowledge and the obtained estimators of vagal and sympathetic activities were compared to traditional markers associated with baroreflex sensitivity."

According to the news editors, the research concluded: "High correlations were observed between traditional markers and model-based indices."

Our news journalists report that additional information may be obtained by contacting V. Le Rolle, University of Rennes, LTSI, F-35000 Rennes, France. Additional authors for this research include A. Beuchee, J.P. Praud, N. Samson, P. Pladys and A. Hernandez.

The direct object identifier (DOI) for that additional information is: http://dx.doi.org/10.1007/s10441-016-9295-y. This DOI is a link to an online electronic document that is either free or for purchase.

Researchers from University of Rome Describe Findings in Epithelial Ovarian Cancer [Brain metastases in patients with EOC: Clinico-pathological and prognostic factors. A multicentric retrospective analysis from the MITO group (MITO 19)]

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Oncology - Epithelial Ovarian Cancer. According to news reporting originating from Rome, Italy, by NewsRx correspondents, research stated, "Brain metastases (BM) from epithelial ovarian cancer (EOC) are considered a rare and unfavourable event. There is no consensus regarding the best management of these patients."

Our news editors obtained a quote from the research from the University of Rome, "A multicenter retrospective analysis of patients with BM from EOC treated between 1997 and 2014 in 18 institutions of the MITO (Multicenter Italian Trials in Ovarian cancer) group was conducted. Univariate and multivariate analysis were performed. A total of 174 women were identified as having BM from EOC. The median time interval between primary diagnosis of EOC and occurrence of BM was 26 months (range 2-129 months). The median overall survival from primary EOC diagnosis was 48 months (95% CI 39.5-56.4 months) and from diagnosis of BM was 12 months (95% CI 9.6-14.3 months). The majority of enrolled women (81.7%) were classified as sensitive to platinum-based chemotherapy. Four variables were significantly associated with poor overall survival in multivariate analysis: multiple BM [HR: 1.86 (95% CI: 1.22-2.84)], presence of extracranial disease [HR: 1.77 (95% CI: 1.11-2.83)] age [HR: 1.74 (95% CI: 1.17-2.59)], and monotherapy [HR: 2.57 (95% CI: 1.64-3.86)]. On the contrary, residual tumor at primary surgery, FIGO stage at primary diagnosis and platinum sensitivity were found to have no significant impact on survival from diagnosis of brain lesions. Our results suggest that BM is a rare and late manifestation of EOC, with a 12-month life-span expectation."

According to the news editors, the research concluded: "Multiple approach is a positive independent prognostic factor and should be proposed to carefully selected patients."

For more information on this research see: Brain metastases in patients with EOC: Clinico-pathological and prognostic factors. A multicentric retrospective analysis from the MITO group (MITO 19). Researchers from University of Rome Detail Findings in Membrane Transport Proteins (Two molecular assays for the rapid and inexpensive detection of GJB2 and GJB6 mutations)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Carrier Proteins - Membrane Transport Proteins have been published. According to news reporting originating from Rome, Italy, by NewsRx correspondents, research stated, "The hypoacusia can be classified in two clinical forms: Syndromic (SHL) and Nonsyndromic (NSHL). In particular, the NSHL describes the 70-80% of hypoacusia cases and it is mainly due to genetic factors, which are causative of the deafness at the birth."

Our news editors obtained a quote from the research from the University of Rome, "The genetic hypoacusia presents different inheritance patterns: autosomal dominant (20%), autosomal recessive (80%), X-linked (1%), and mitochondrial (1%), respectively. To date, about 35 deafness-causative genes have been identified and most of them codify for connexin transmembrane proteins. Approximately 1:2500 children with NSHL carries mutations in the GJB2 and GJB6 (13q12) genes, which code for connexin 26 (Cx26) and connexin 30 (C30), respectively. In the Caucasian population, the most common mutations are 35delG, M34T and 167delT, and D13S1830. Given the frequency distribution of the four mutations in the Caucasian population and the pathogenic connection with NSHL, the development of accurate, rapid, and 'low-cost' molecular assays should be strongly encouraged. To this purpose, we set up two different molecular assays (namely the Cx26 and Cx26-30 molecular assays) for the fast and inexpensive detection of 35delG, M34T, 167delT, and D13S1830 mutations. Both the molecular approaches showed to be accurate, sensitive, reproducible, and 'low-cost' alternatives for the proper evaluation of the GJB2 and GJB6 genes, which are causative of NSHL."

According to the news editors, the research concluded: "The Cx26 and Cx26-30 molecular assays can be applied to individual, preconception, prenatal, or postnatal screening for the causative-mutations of NSHL."

The news editors report that additional information may be obtained by contacting R. Cascella, Dept. of Biomedicine and Prevention, School of Medicine, University of Rome Tor Vergata, Rome, Italy. Additional authors for this research include C. Strafella, S. Gambardella, G. Longo, P. Borgiani, F. Sangiuluo, G. Novelli and E. Giardina.

Researchers from University of Saarland Describe Findings in Alzheimer Disease (Tocotrienol Affects Oxidative Stress, Cholesterol Homeostasis and the Amyloidogenic Pathway in Neuroblastoma Cells: Consequences for Alzheimer's Disease)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Neurodegenerative Diseases and Conditions - Alzheimer Disease have been published. According to news reporting out of Homburg, Germany, by NewsRx editors, research stated, "One of the characteristics of Alzheimer's disease (AD) is an increased amyloid load and an enhanced level of reactive oxidative species (ROS). Vitamin E has known beneficial neuroprotective effects, and previously, some studies suggested that vitamin E is associated with a reduced risk of AD due to its antioxidative properties."

Our news journalists obtained a quote from the research from the University of Saarland, "However, epidemiological studies and nutritional approaches of vitamin E treatment are controversial. Here, we investigate the effect of alpha-tocotrienol, which belongs to the group of vitamin E, on AD-relevant processes in neuronal cell lines. In line with the literature, alpha-tocotrienol reduced the ROS level in SH-SY5Y cells. In the presence of tocotrienols, cholesterol and cholesterol esters, which have been shown to be risk factors in AD, were decreased. Besides the unambiguous positive effects of tocotrienol, amyloid-beta (A beta) levels were increased accompanied by an increase in the activity of enzymes responsible for A beta production. Proteins and gene expression of the secretases and their components remained unchanged, whereas tocotrienol accelerates enzyme activity in cell-free assays. Besides enhanced A beta production, tocotrienols inhibited A beta degradation in neuro 2a (N2a)-cells."

According to the news editors, the research concluded: "Our results might help to understand the controversial findings of vitamin E studies and demonstrate that besides the known positive neuroprotective properties, tocotrienols also have negative characteristics with respect to AD."

For more information on this research see: Tocotrienol Affects Oxidative Stress, Cholesterol Homeostasis and the Amyloidogenic Pathway in Neuroblastoma Cells: Consequences for Alzheimer's Disease. *International Journal of Molecular Sciences, 2016;17 (11):752-769. Researchers from University of Saarland Discuss Findings in Myeloid Cells [Induction of Glucocorticoid-induced Leucine Zipper (GILZ) Contributes to Anti-inflammatory Effects of the Natural Product Curcumin in Macrophages]

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Myeloid Cells. According to news reporting originating from Saarbrucken, Germany, by NewsRx correspondents, research stated, "GILZ (glucocorticoid-induced leucine zipper) is inducible by glucocorticoids and plays a key role in their mode of action. GILZ attenuates inflammation mainly by inhibition of NF-kappa B and mitogen-activated protein kinase activation but does not seem to be involved in the severe side effects observed after glucocorticoid treatment."

Financial support for this research came from Deutsche Forschungsgemeinschaft.

Our news editors obtained a quote from the research from the University of Saarland, "Therefore, GILZ might be a promising target for new therapeutic approaches. The present work focuses on the natural product curcumin, which has previously been reported to inhibit NF-kappa B. GILZ was inducible by curcumin in macrophage cell lines, primary human monocyte-derived macrophages, and murine bone marrow-derived macrophages. The up-regulation of GILZ was neither associated with glucocorticoid receptor activation nor with transcriptional induction or mRNA or protein stabilization but was a result of enhanced translation. Because the GILZ 3'-UTR contains AU-rich elements (AREs), we analyzed the role of the mRNA-binding protein HuR, which has been shown to promote the translation of ARE-containing mRNAs. Our results suggest that curcumin treatment induces HuR expression. An RNA immunoprecipitation assay confirmed that HuR can bind GILZ mRNA. In accordance, HuR overexpression led to increased GILZ protein levels but had no effect on GILZ mRNA expression. Our data employing siRNA in LPS-activated RAW264.7 macrophages show that curcumin facilitates its anti-inflammatory action by induction of GILZ in macrophages. Experiments with LPS-activated bone marrow-derived macrophages from wild-type and GILZ knock-out mice demonstrated that curcumin inhibits the activity of inflammatory regulators, such as NF-kappa B or ERK, and subsequent TNF-kappa production via GILZ."

According to the news editors, the research concluded: "In summary, our data indicate that HuR-dependent GILZ induction contributes to the anti-inflammatory properties of curcumin."

The news editors report that additional information may be obtained by contacting A.K. Kiemer, University of Saarland, Dept. of Pharm, Pharmaceut Biol, D-66041 Saarbrucken, Germany. Additional authors for this research include N. Hachenthal, J.V. Valbuena-Perez, S.
Researchers from University of Sao Paulo Discuss Findings in Human Genetics (Twinning and Multiple Birth Rates According to Maternal Age in the City of Sao Paulo, Brazil: 2003-2014)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Genetics - Human Genetics.

According to news reporting originating in Sao Paulo, Brazil, by NewsRx journalists, research stated, "The present study investigates the twinning rates in the city of Sao Paulo, Brazil, during the years 2003-2014. The data were drawn from the Brazilian Health Department database of Sistema de Informacoes de Nascidos Vivos de Sao Paulo-SINASC (Live Births Information System of Sao Paulo)."

The news reporters obtained a quote from the research from the University of Sao Paulo, "In general, more information is available on the incidence of twinning in developed countries than in developing ones. A total of 24,589 twin deliveries and 736 multiple deliveries were registered in 140 hospitals of Sao Paulo out of a total of 2,056,016 deliveries during the studied time period. The overall average rates of singleton, twin, and multiple births per 1,000 maternities (%) were 987.43, 11.96 (dizygotic (DZ) rate was 7.15 and monozygotic (MZ) 4.42), and 0.36, respectively. We further regressed maternal age and historical time period on percentage of singleton, twin, and multiple birth rates. Our results indicated that maternal age strongly positively predicted twin and multiple birth rates, and negatively predicted singleton birth rates. The historical time period also positively, although weakly, predicted twin birth rates, and had no effect on singleton or multiple birth rates. Further, after applying Weinberg's differential method, we computed regressions separately for the estimated frequencies of DZ and MZ twin rates. DZ twinning was strongly positively predicted by maternal age and, to a smaller degree, by time period, while MZ twinning increased marginally only with higher maternal age. Factors such as increasing body mass index or air pollution can lead to the slight historical increase in DZ twinning rates. Importantly, consistent with previous cross-cultural and historical research, our results support the existence of an age-dependent physiological mechanism that leads to a strong increase in twinning and multiple births, but not singleton births, among mothers of higher age categories."

According to the news reporters, the research concluded: "From the ultimate
perspective, twinning and multiple births in later age can lead to higher individual reproductive success near the end of the reproductive career of the mother."

Our news correspondents report that additional information may be obtained by contacting J.V. Valentova, University of Sao Paulo, Inst Psychol, Dept. of Expt Psychol, BR-05508030 Sao Paulo, Brazil. **Oncology - Pituitary Cancer**

**Researchers from University of Sao Paulo Report New Studies and Findings in the Area of Pituitary Cancer (P27/CDKN1B Translational Regulators in Pituitary Tumorigenesis)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Oncology - Pituitary Cancer have been presented. According to news reporting originating in Sao Paulo, Brazil, by NewsRx journalists, research stated, "In pituitary tumors, P27(CDKN1B) is underexpressed. We aimed to clarify whether translational regulation underlies this phenomenon."

The news reporters obtained a quote from the research from the University of Sao Paulo, "This study evaluated the expression of P27/CDKN1B, its targets (CCNE1, CDK2) and translational regulators (DKC1, RPS13, miR221, miR222) and screened for DKC1 variants in sporadic pituitary adenomas. Samples were obtained during transsphenoidal surgery from 48 patients with pituitary adenomas: 10 ACTH-, 17 GH-secreting, and 21 nonfunctioning (NFPA). The control group comprised 7 normal pituitaries (NP) obtained during autopsies. Gene expression was assessed by RT-PCR and protein expression by immunohistochemistry. The 15 exons of DKC1 were sequenced. P27 protein underexpression was observed in all adenomas subtypes (p = 0.001). CCNE1 mRNA (p = 0.01) overexpression, but not protein, was observed in NFPA. No differential gene expression among groups was observed in CDKN1B regulators RPS13 (p = 0.23) and DKC1 (p = 0.34). The expression of miR221 and miR222 was similar among tumors and NP. Frequent DKC1 variants (SNPs) were found in exon 14 and in the 3'-UTR in similar frequency to NCBI-dsSNP databases. We also observed rare DKC1 variants in 11% of the studied tumor samples, indicating a high prevalence in pituitary adenomas, however, in silico studies failed to indicate deleterious effects. The high frequency of DKC1 variants may influence, in some extent, pituitary tumors development, without clear role in its tumorigenesis."

According to the news reporters, the research concluded: "Our data reinforce the P27 underexpression in pituitary adenomas and provide further evidence of the post-translational
machinery involvement, although this phenomenon cannot be explained either by mis-expression of P27 translational regulators - DKC1, RPS13, miR221, miR222 - or directly by DKC1 mutations."

For more information on this research see: P27/CDKN1B Translational Regulators in Pituitary Tumorigenesis. *Hormone and Metabolic Research*, 2016;48(12):840-846. *Hormone and Metabolic Research* can be contacted at: Georg Thieme Verlag Kg, Rudigerstr 14, D-70469 Stuttgart, Germany. **Drug Administration Routes**

**Researchers from University of Seoul Report Details of New Studies and Findings in the Area of Drug Administration Routes [Induction of Flavin-Containing Monooxygenase in Mice by Oral Administration of Phellinus baumii (Agaricomycetes) Extract]**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Drug Administration Routes. According to news reporting originating from Seoul, South Korea, by NewsRx correspondents, research stated, "Phellinus baumii is a yellow mushroom long used in alternative medicine in Korea and other central Asian countries. To identify genes affected by a single or 7-day oral administration of a water extract of Ph.

Our news editors obtained a quote from the research from the University of Seoul, "Baumii, mouse liver tissue was analyzed using microarrays. The results showed that 8 and 23 genes were upregulated and 3 and 11 genes downregulated more than 3-fold by single and multiple oral administrations of 100 mg/kg PBE, respectively. Among the upregulated genes, the expression of 3 flavin-containing monooxygenase (Fmo) family genes, Fmo2-4, was upregulated in a concentration-dependent manner. The microarray analysis also showed that single and multiple administrations of PBE increased Fmo3 expression in the mouse liver by 5.1- and 17.6-fold, respectively. To validate the Fmo expression microarray data, polymerase chain reaction was used to confirm the induction of Fmo subclass genes. Mice were orally administered Ph. Baumii extract (PBE), Ph. Baumii water, or Ph. Baumii beta-glucan fraction (PBG) for 7 days, and induction of the expression of the Fmo subclasses in the liver, lung, and kidney was investigated. Fmo2, Fmo3, and Fmo4 expression was induced by both PBE and PBG in the lung, liver, and kidney, respectively. However, no induction of Fmo1 and Fmo5 was detected. To investigate the metabolic acceleration of xenobiotic by PBE, carbendazim was orally administered to mice and its clearance from the blood analyzed. High-performance liquid
chromatography analysis showed accelerated clearance of serum carbendazim by oral administration of PBE for 7 days, as evidenced by the reduced peak plasma concentration, time to reach the peak plasma concentration, and area under the curve values. Moreover, PBE increased the carbendazim clearance rate at the higher concentration. These data indicate that oral administration of PBE resulted in modulation of gene expression: PBE was responsible for the induction of Fmo2, Fmo3, and Fmo4 expression.

According to the news editors, the research concluded: "PBE also accelerated the metabolic clearance of carbendazim in vivo and so could be applied to the detoxification of xenobiotics such as drugs, pesticides, and nicotine."

For more information on this research see: Induction of Flavin-Containing Monooxygenase in Mice by Oral Administration of Phellinus baumii (Agaricomycetes) Extract. *International Journal of Medicinal Mushrooms*, 2016;18(9):793-806. *International Journal of Medicinal Mushrooms* can be contacted at: Begell House Inc, 50 North St, Danbury, CT 06810, USA.

The news editors report that additional information may be obtained by contacting H.W. Kim, Univ Seoul, Dept. of Life Sci, Seoul 02504, South Korea. Additional authors for this research include B.S. Park and H.W. Kim.

**Researchers from University of Shandong Describe Findings in Biological Tumor Markers (Reference Intervals of Alpha-Fetoprotein and Carcinoembryonic Antigen in the Apparently Healthy Population)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Biological Factors - Biological Tumor Markers is the subject of a report. According to news reporting originating from Shandong, People's Republic of China, by NewsRx correspondents, research stated, "The aim of this study was to calculate 95% reference intervals and double-sided limits of serum alpha-fetoprotein (AFP) and carcinoembryonic antigen (CEA) according to the CLSI EP28-A3 guideline. Serum AFP and CEA values were measured in samples from 26 000 healthy subjects in the Shuyang area receiving general health checkups."

Our news editors obtained a quote from the research from the University of Shandong, "The 95% reference intervals and upper limits were calculated by using MedCalc. We provided continuous reference intervals from 20 years old to 90 years old for AFP and CEA. The reference intervals were: AFP, 1.31-7.89 ng/ml (males) and 1.01-7.10 ng/ml (females); CEA, 0.51-4.86 ng/ml (males) and 0.35-3.45ng/ml (females). AFP and CEA were significantly positively correlated with age in both males (r=0.196 and r=0.198) and females (r=0.121 and r=0.197). Different races or populations and different detection systems may result in different
According to the news editors, the research concluded: "Continuous reference intervals of age changes are more accurate than age groups."

For more information on this research see: Reference Intervals of Alpha-Fetoprotein and Carcinoembryonic Antigen in the Apparently Healthy Population. *Medical Science Monitor*, 2016;22():4875-4880. *Medical Science Monitor* can be contacted at: Int Scientific Literature, Inc, 361 Forest Lane, Smithtown, NY 11787, USA.

The news editors report that additional information may be obtained by contacting X.X. Guo, Shandong Univ Tradit Chinese Med, Affiliated Hosp, Dept. of Lab Med, Jinan, Shandong, People's Republic of China. Additional authors for this research include X.X. Guo, X.B. Ma and G.M. Zhang.

**Immunology - Lymphoid Tissue**

**Researchers from University of South Australia Describe Findings in Lymphoid Tissue (Toward Intraoperative Detection of Disseminated Tumor Cells in Lymph Nodes with Silicon Nanowire Field Effect Transistors)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Immunology - Lymphoid Tissue have been published. According to news reporting from Mawson Lakes, Australia, by NewsRx journalists, research stated, "Within an hour, as little as one disseminated tumor cell (DTC) per lymph node can be quantitatively detected using an intraoperative biosensing platform based on silicon nanowire field-effect transistors (SiNW FET). It is also demonstrated that the integrated biosensing platform is able to detect the presence of circulating tumor cells (CTCs) in the blood of colorectal cancer patients."

Funders for this research include German Academic Exchange Service, National Health and Medical Research Council, Australian Technology Network of Universities.

The news correspondents obtained a quote from the research from the University of South Australia, "The presence of DTCs in lymph nodes and CTCs in peripheral blood is highly significant as it is strongly associated with poor patient prognosis. The SiNW FET sensing platform out-performed in both sensitivity and rapidity not only the current standard method based on pathological examination of tissue sections but also the emerging clinical gold standard based on molecular assays. The possibility to achieve accurate and highly sensitive analysis of the presence of DTCs in the lymphatics within the surgery time frame has the potential to spare cancer patients from an unnecessary secondary surgery, leading to reduced..."
patient morbidity, improving their psychological wellbeing and reducing time spent in hospital."

According to the news reporters, the research concluded: "This study demonstrates the potential of nanoscale field-effect technology in clinical cancer diagnostics."

Our news journalists report that additional information may be obtained by contacting D.P. Tran, Future Industries Institute, University of South Australia, Mawson Lakes Campus, Mawson Lakes, South Australia 5095, Australia. Additional authors for this research include M.A. Winter, B. Wolfrum, R. Stockmann, C.T. Yang, M. Pourhassan-Moghaddam, A. Offenhausser and B. Thierry.

**Drugs and Therapies - Clinical Pharmacology**

**Researchers from University of South Florida Describe Findings in Clinical Pharmacology (Addressing potential role of magnesium dyshomeostasis to improve treatment efficacy for epilepsy: A reexamination of the literature)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Drugs and Therapies - Clinical Pharmacology are discussed in a new report. According to news reporting from Tampa, Florida, by NewsRx journalists, research stated, "Magnesium (Mg(2+)) is an abundant mineral in the body serving many biochemical functions. Magnesium supplementation has been shown to raise seizure threshold in animal and human studies, but the etiological contribution of magnesium deficiency to the onset and maintenance of epilepsy, as well as the degree to which it impacts antiepileptic drug efficacy, remains poorly understood."

The news correspondents obtained a quote from the research from the University of South Florida, "This may be due, at least in part, to the inherent limitations of commonly used serum levels as a measure of functional magnesium status, as well as insufficient data regarding relative bioavailabilities of various magnesium salts and chelates for use with humans. To date, 1 randomized clinical trial has been conducted assessing Mg(2+) supplementation in epilepsy, and findings yielded promising results. Yet a notable dearth in the literature remains, and more studies are needed. To better understand the potential role of magnesium deficiency as a causal factor in epilepsy, more convenient and accurate measurement methods should to be developed and employed in randomized, controlled trials of oral magnesium supplementation in epilepsy."

According to the news reporters, the research concluded: "Findings from such studies have the potential to facilitate far-reaching clinical and economic improvements in
epilepsy treatment standards."

For more information on this research see: Addressing potential role of magnesium dyshomeostasis to improve treatment efficacy for epilepsy: A reexamination of the literature. Journal of Clinical Pharmacology, 2015;56(3):260-5. Journal of Clinical Pharmacology can be contacted at: SAGE Publications, USA, 2455 Teller Road, Thousand Oaks, CA 91320, USA. Genetics - Human Genetics

Researchers from University of Southern Denmark Report Recent Findings in Human Genetics (Change in Depression Symptomatology and Cognitive Function in Twins: A 10-Year Follow-Up Study)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Genetics - Human Genetics is now available. According to news reporting originating in Odense, Denmark, by NewsRx journalists, research stated, "A complex interrelation exists between change in depression symptomatology and cognitive decline. Studies indicate either that depression is a direct risk factor for cognitive change over time, or vice versa."

The news reporters obtained a quote from the research from the University of Southern Denmark, "Longitudinal twin studies provide the possibility to unravel cause and effect of correlated traits. Here, we have applied twin modeling approaches to shed light on the genetic correlation between both level and change of depression symptomatology and cognitive functioning, and to further explore the bidirectionality of any such correlation using assessments of both phenotypes at two occasions 10 years apart. The study included 2,866 Danish twins with a mean age of 56.8 years at intake (range: 45-68 years). Of these, 1,267 were intact pairs. A total number of 1,582 twins (55%), of whom 557 were intact pairs, participated in the follow-up survey. We found stable cross-sectional heritability estimates of approximately 60% for general cognitive abilities and 30% for affective depressive symptoms. There was a considerable decline in the mean cognitive performance over 10 years, whereas the mean affective depression symptoms score was stable and with no genetic contribution to any individual change. Additionally, we saw a small but significant cross-trait correlation at both occasions (-0.11 and -0.09, respectively), but cross-trait cross-occasion analysis revealed no evidence that either of the
According to the news reporters, the research concluded: "Thus, our study was not able to detect any causal association between change in depressive symptomatology and cognitive decline in middle-aged and elderly people over a 10-year interval."

Our news correspondents report that additional information may be obtained by contacting I. Petersen, The Danish Twin Registry, Unit of Epidemiology, Biostatistics and Biodemography, Institute of Public Health, University of Southern Denmark, Odense, Denmark. Additional authors for this research include M. McGue, Q. Tan, K. Christensen and L. Christiansen.

**Stem Cell Research - Hematopoietic Stem Cells**

**Researchers from University of Strasbourg Report Findings in Hematopoietic Stem Cells (Origin of the hematopoietic system in the human embryo)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Stem Cell Research - Hematopoietic Stem Cells have been presented. According to news reporting originating in Strasbourg, France, by NewsRx journalists, research stated, "The continuous generation of blood cells throughout life relies on the existence of hematopoietic stem cells (HSC) generated during embryogenesis. Given the importance of HSC transplantation in cell-based therapeutic approaches, considerable efforts have been made toward understanding the developmental origins of embryonic HSC."

Financial supporters for this research include Etablissement Francais du Sang, Institut National de la Sante et de la Recherche Medicale, Agence Nationale de la Recherche, Fondation ARC pour la Recherche sur le Cancer.

The news reporters obtained a quote from the research from the University of Strasbourg, "Adult-type HSC are first generated in the aorta-gonad-mesonephros (AGM) region between days 27 and 40 of human embryonic development, but an elusive blood-forming potential is present earlier in the underlying splanchnopleura. It is relatively well accepted that the HSC emerge in the AGM through a hemogenic endothelium, but the direct precursor of this cell type remains to be clearly identified. This review is intended to summarize the recent advances made to understand the origins of hematopoietic stem cells in the early human embryo."

According to the news reporters, the research concluded: "In addition, we discuss in detail the discovery of the angiotensin-converting enzyme (ACE) as a novel marker of human
HSC and of prehematopoietic precursors inside the embryo."

Our news correspondents report that additional information may be obtained by contacting M. Tavian, Univ Strasbourg, Etab Francais Sang ALCA, INSERM, UMR S949, F-67065 Strasbourg, France. Additional authors for this research include R. El Omar and M. Tavian.

Materials Research - Applied Materials & Interfaces

Researchers from University of Sydney Detail Findings in Applied Materials & Interfaces (Fabrication of Semiordered Nanopatterned Diamond-like Carbon and Titania Films for Blood Contacting Applications)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Materials Research - Applied Materials & Interfaces are discussed in a new report. According to news reporting from Sydney, Australia, by NewsRx journalists, research stated, "Biomaterials with the ability to interface with, but not activate, blood components are essential for a multitude of medical devices. Diamond-like carbon (DLC) and titania (TiO2) have shown promise for these applications; however, both support platelet adhesion and activation."

Financial support for this research came from Australian Research Council.

The news correspondents obtained a quote from the research from the University of Sydney, "This study explored the fabrication of nanostructured DLC and TiO2 thin film coatings using a block copolymer deposition technique that produced semiordered nanopatterns with low surface roughness (5-8 nm Rrms). These surfaces supported fibrinogen and plasma protein adsorption that predominantly adsorbed between the nanofeatures and reduced the overall surface roughness. The conformation of the adsorbed fibrinogen was altered on the nanopatterned surfaces as compared with the planar surfaces to reveal higher levels of the platelet binding region. Planar DLC and TiO2 coatings supported less platelet adhesion than nanopatterned DLC and TiO2. However, platelets on the nanopatterned DLC coatings were less spread indicating a lower level of platelet activation on the nanostructured DLC coatings compared with the planar DLC coatings."

According to the news reporters, the research concluded: "These data indicated that nanostructured DLC coatings may find application in blood contacting medical devices in the

Our news journalists report that additional information may be obtained by contacting D. Nandakumar, Biomedical Engineering, School of AMME, University of Sydney, Sydney, New South Wales 2007, Australia. Additional authors for this research include A. Bendavid, P.J. Martin, K.D. Harris, A.J. Ruys and M.S Lord.

Heart Disorders and Diseases - Sinus Tachycardia

Researchers from University of Sydney Detail Findings in Sinus Tachycardia (Inappropriate sinus tachycardia: focus on ivabradine)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Heart Disorders and Diseases - Sinus Tachycardia are discussed in a new report. According to news reporting originating in Sydney, Australia, by NewsRx journalists, research stated, "Inappropriate sinus tachycardia (IST) is an incompletely understood condition, characterised by an elevation in heart rate (HR) accompanied by wide ranging symptoms in the absence of an underlying physiological stimulus. The condition often takes a chronic course with significant adverse effects on quality of life."

The news reporters obtained a quote from the research from the University of Sydney, "Currently, there is no effective treatment for IST. Beta-blockers, generally considered the cornerstone of treatment, are often ineffective and poorly tolerated. Ivabradine is a novel sinus node I-f funny current' inhibitor, which reduces the HR. It has been approved for the treatment of beta-blocker refractory chronic systolic heart failure and chronic stable angina but more recently has shown promise in the treatment of IST."

According to the news reporters, the research concluded: "This review provides an overview of IST prevalence and mechanisms followed by an examination of the evidence for the role and efficacy of ivabradine in the treatment of IST."

Our news correspondents report that additional information may be obtained by contacting A.C. Keech, University of Sydney, NHMRC Clin Trials Center, Sydney, NSW 2006, Australia. Additional authors for this research include J.R. Fulcher, M.J. Kilborn and A.C. Keech.
Researchers from University of Sydney Provide Details of New Studies and Findings in the Area of Mental Health (The Mental Health of British Adults with Intellectual Impairments Living in General Households)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Mental Health have been presented. According to news reporting from Sydney, Australia, by NewsRx journalists, research stated, "People with intellectual disability or borderline intellectual functioning may have poorer mental health than their peers. The present authors sought to (i) estimate the risk of poorer mental health among British adults with and without intellectual impairments and (ii) estimate the extent to which any between-group differences in mental health may reflect between-group differences in rates of exposure to common social determinants of poorer health."

Financial support for this research came from Public Health England.

The news correspondents obtained a quote from the research from the University of Sydney, "The present authors undertook secondary analysis of confidentialized unit records collected in Wave 3 of Understanding Society. British adults with intellectual impairments living in general households are at significantly increased risk of potential mental health problems than their non-disabled peers (e.g. GHQ Caseness OR = 1.77, 95% CI (1.25-2.52), P< 0.001). Adjusting for between-group differences in age, gender and indicators of socio-economic position eliminated this increased risk [GHQ Caseness adjusted OR = 1.06, 95% CI (0.73-1.52), n.s]. Our analyses are consistent with the hypothesis that the increased risk of poor mental health among people with intellectual impairments may be attributable to their poorer living conditions rather than their intellectual impairments per se."

According to the news reporters, the research concluded: "Greater attention should be given to understanding and addressing the impact of exposure to common social determinants of mental health among marginalized or vulnerable groups."

Our news journalists report that additional information may be obtained by contacting E. Emerson, University of Sydney, Center Disabil Res & Policy, Sydney, NSW, Australia. Additional authors for this research include E. Emerson, J. Robertson and S. Baines.

Researchers from University of Sydney Report Details of New Studies and Findings in the Area of Type 2 Diabetes (Impact of Perturbed Pancreatic beta-Cell Cholesterol Homeostasis on Adipose Tissue and Skeletal Muscle Metabolism)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Nutritional and Metabolic Diseases and Conditions - Type 2 Diabetes are presented in a new report. According to news originating from Sydney, Australia, by NewsRx correspondents, research stated, "Elevated pancreatic beta-cell cholesterol levels impair insulin secretion and reduce plasma insulin levels. This study establishes that low plasma insulin levels have a detrimental effect on two major insulin target tissues: adipose tissue and skeletal muscle."

Our news journalists obtained a quote from the research from the University of Sydney, "Mice with increased beta-cell cholesterol levels were generated by conditional deletion of the ATP-binding cassette transporters, ABCA1 and ABCG1, in beta-cells (beta-DKO mice). Insulin secretion was impaired in these mice under basal and high-glucose conditions, and glucose disposal was shifted from skeletal muscle to adipose tissue. The beta-DKO mice also had increased body fat and adipose tissue macrophage content, elevated plasma interleukin-6 and MCP-1 levels, and decreased skeletal muscle mass. They were not, however, insulin resistant. The adipose tissue expansion and reduced skeletal muscle mass, but not the systemic inflammation or increased adipose tissue macrophage content, were reversed when plasma insulin levels were normalized by insulin supplementation. These studies identify a mechanism by which perturbation of beta-cell cholesterol homeostasis and impaired insulin secretion increase adiposity, reduce skeletal muscle mass, and cause systemic inflammation."

According to the news editors, the research concluded: "They further identify beta-cell dysfunction as a potential therapeutic target in people at increased risk of developing type 2 diabetes."

For more information on this research see: Impact of Perturbed Pancreatic beta-Cell Cholesterol Homeostasis on Adipose Tissue and Skeletal Muscle Metabolism. Diabetes, 2016;65(12):3610-3620. Diabetes can be contacted at: Amer Diabetes Assoc, 1701 N Beauregard St, Alexandria, VA 22311-1717, USA. Researchers from University of Tartu Report Findings in Escherichia coli (Plasmid with Colistin Resistance Gene mcr-1 in Extended-Spectrum-beta-Lactamase-Producing Escherichia coli Strains Isolated from Pig Slurry in Estonia)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Gram-Negative Bacteria - Escherichia coli. According to news reporting from Tartu, Estonia, by NewsRx journalists, research stated, "A plasmid carrying the colistin resistance gene mcr-1 was isolated from a pig slurry sample in Estonia."

The news correspondents obtained a quote from the research from the University of Tartu, "The gene was present on a 33,311-bp plasmid of the IncX4 group. mcr-1 is the only antibiotic resistance gene on the plasmid, with the other genes mainly coding for proteins involved in conjugative DNA transfer (taxA, taxB, taxC, trbM, and the pilX operon)."

According to the news reporters, the research concluded: "The plasmid pESTMCR was present in three phylogenetically very different Escherichia coli strains, suggesting that it has high potential for horizontal transfer."

Our news journalists report that additional information may be obtained by contacting T. Tenson, University of Tartu, Inst Technol, Tartu, Estonia. Additional authors for this research include K. Telling, M. Laht, P. Kalmus, I. Lutsar, M. Remm, V. Kisand and T. Tenson.

Researchers from University of Tehran Detail New Studies and Findings in the Area of Clinical Trials and Studies (Minocycline combination therapy with fluvoxamine in moderate-to-severe obsessive-compulsive disorder: A placebo-controlled, ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Clinical Research - Clinical Trials and Studies. According to news reporting out of Tehran, Iran, by NewsRx editors, research stated, "Several lines of evidence implicate glutamatergic dysfunction in the pathophysiology of obsessive-compulsive disorder (OCD), presenting this neurotransmitter as a target for the development of novel pharmacotherapy. The objective of this study was to assess the efficacy of minocycline as an augmentative agent to fluvoxamine in the treatment of patients with OCD."

Our news journalists obtained a quote from the research from the University of Tehran, "One hundred and two patients with the diagnosis of moderate-to-severe OCD were recruited to this study. A randomized double-blind trial was designed and patients received either L-carnosine or placebo as adjuvant to fluvoxamine for 10 weeks. The patients randomly received either minocycline 100 mg twice per day or placebo for 10 weeks. All patients received fluvoxamine (100 mg/day) for the first 4 weeks, followed by 200 mg/day for the rest of the trial, regardless of their treatment groups. Participants were evaluated using the Yale-Brown Obsessive Compulsive Scale (Y-BOCS). The main outcome measure was to assess the efficacy of minocycline in improving the OCD symptoms. General linear model repeated measures demonstrated significant effect for time x treatment interaction on the Y-BOCS total scores, F (1.49, 137.93) = 7.1, P = 0.003, and Y-BOCS Obsession subscale score, F(1.54, 141.94) = 9.72, P = 0.001, and near significant effect for the Y-BOCS Compulsion subscale score, F(1.27, 117.47) = 2.92, P = 0.08. A significantly greater rate of partial and complete response was observed in the minocycline group (P < 0.001). The frequency of side-effects was not significantly different between the treatment arms."

According to the news editors, the research concluded: "The results of this study suggest that minocycline could be a tolerable and effective adjuvant in the management of patients with OCD."

Our news journalists report that additional information may be obtained by contacting S. Akhondzadeh, Univ Tehran Med Sci, Roozbeh Hosp, Psychiat Res Center, Tehran, Iran. Additional authors for this research include Z. Abrishami, A. Zeinoddini, F. Rahiminejad, M. Sadeghi, M.R. Najjarzadegan, M.R. Shalbafan and S. Akhondzadeh.

Keywords for this news article include: Tehran, Iran, Asia, Selective Serotonin Reuptake Inhibitors, Obsessive-Compulsive Disorder, Clinical Trials and Studies, Psychotherapeutic Agents, Drugs and Therapies, Combination Therapy, Fluvoxamine Therapy, Clinical Research, Antidepressants, Antinfectives, Mental Health, Tetracyclines, Minocycline, Antibiotics, Antianxiety, Oximes, University of Tehran.
Researchers from University of Tehran Report on Findings in Acute Lymphoblastic Leukemia (Inhibition of tachykinin NK1 receptor using aprepitant induces apoptotic cell death and G1 arrest through Aktp53 axis in pre-B acute lymphoblastic ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Oncology - Acute Lymphoblastic Leukemia are discussed in a new report. According to news originating from Tehran, Iran, by NewsRx correspondents, research stated, "Increasing number of genetic and cancer biology studies indicated a prominent role for tachykinin NK1 receptor (Will) in cancer cell growth and survival. Considering the fact that neoplastic lymphoid precursors in acute lymphoblastic leukemia (ALL) carry a three- to four-fold NK1R expression as compared to normal lymphocytes, using Will antagonist seems to be noteworthy in the treatment of ALL patients."

Our news journalists obtained a quote from the research from the University of Tehran, "In this study, we found that inhibition of Will with aprepitant, a selective high-affinity antagonist of the human NKiR, exerts cytotoxic and anti-proliferative effects against pre-B ALL-derived Nalm-6 cells either as single drug or in combination with doxorubicin. Our data showed that treatment of the cells with the inhibitor resulted in apoptotic cell death, at least partly, through abrogation of PI3K/Akt pathway, as revealed by the reduction of phospho/total Akt ratio. In agreement with the inhibitory effect on Akt, we also found that aprepitant increased the expression level of p21 and p27, which in turn leads to the induction of G1 cell cycle arrest."

According to the news editors, the research concluded: "Overall, this study recommends mechanistic pathways by which inhibition of Will can augment apoptotic cell death through a plausible p53-dependent pathway rather than NF-kappa B-dependened mechanism in pre-B ALL cells; however, further studies are needed to better characterize the application of NK1R inhibition in clinical cancer treatment."

For more information on this research see: Inhibition of tachykinin NK1 receptor using aprepitant induces apoptotic cell death and G1 arrest through Aktp53 axis in pre-B acute lymphoblastic leukemia cells. Researchers from University of Tennessee Report Findings in Aneurysm (The first North American use of the Pipeline Flex flow diverter)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Cardiovascular Diseases and Conditions - Aneurysm are discussed in a new report. According to news reporting out of Memphis, Tennessee, by NewsRx editors, research stated, "Flow diversion for the management of intracranial aneurysms represents a paradigm shift in how aneurysms are managed. The Pipeline embolization device (PED) is, to date, the only flow diverter approved for use in the USA by the Food and Drug Administration."

Our news journalists obtained a quote from the research from the University of Tennessee, "Limitations and complications with new treatment strategies are inevitable, and with the PED there have been reports of complications, most commonly with challenging deployments. Once deployment has been initiated, the device is 'one-way'; it can only be deployed further or removed. Yet, situations arise in which the ability to recapture or reposition the device would be advantageous. A second-generation Pipeline has been developed that addresses these concerns. We report the first use in North America of this second-generation Pipeline device: the Pipeline Flex."

According to the news editors, the research concluded: "We discuss our rationale for using the device, our impressions of its operation, and the relevant literature concerning the current state of flow diversion."

Our news journalists report that additional information may be obtained by contacting A.S. Arthur, University of Tennessee, Center Hlth Sci, Dept. of Neurosurg, Memphis, TN 38163, United States. Additional authors for this research include C. Nickele, D. Hoit, A. Belayev, C.J. Moran and A.S. Arthur.

Keywords for this news article include: Memphis, Tennessee, United States, North and Central America, Cardiovascular Diseases and Conditions, Aneurysm, University of Tennessee.

Researchers from University of Texas Describe Findings in Glioblastomas (Epigenetic Activation of WNT5A Drives Glioblastoma Stem Cell Differentiation and Invasive Growth)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Oncology - Glioblastomas. According to news originating from Houston, Texas, by NewsRx correspondents, research stated, "Glioblastoma stem cells (GSCs) are implicated in tumor neovascularization, invasiveness, and therapeutic resistance. To illuminate mechanisms governing these hallmark features, we developed a de novo glioblastoma multiforme (GBM) model derived from immortalized human neural stem/progenitor cells (hNSCs) to enable precise system-level comparisons of pre-malignant and oncogene-induced malignant states of NSCs."

Financial supporters for this research include UCSF Brain Tumor SPORE Tissue Bank, NIH, The Ben and Catherine Ivy Foundation Research Award, Clayton Foundation.

Our news journalists obtained a quote from the research from the University of Texas, "Integrated transcriptomic and epigenomic analyses uncovered a PAX6/DLX5 transcriptional program driving WNT5A-mediated GSC differentiation into endothelial-like cells (GdECs). GdECs recruit existing endothelial cells to promote peritumoral satellite lesions, which serve as a niche supporting the growth of invasive glioma cells away from the primary tumor. Clinical data reveal higher WNT5A and GdECs expression in peritumoral and recurrent GBMs relative to matched intratumoral and primary GBMs, respectively, supporting WNT5A-mediated GSC differentiation and invasive growth in disease recurrence."

According to the news editors, the research concluded: "Thus, the PAX6/DLX5-WNT5A axis governs the diffuse spread of glioma cells throughout the brain parenchyma, contributing to the lethality of GBM."

For more information on this research see: Epigenetic Activation of WNT5A Drives Glioblastoma Stem Cell Differentiation and Invasive Growth. Cell, 2016;167(5):1281-1295,270-286. Researchers from University of Texas Medical Branch Detail Findings in Prostaglandin-Endoperoxide Synthases (Bortezomib Effects on Human Microvascular Endothelium in vitro)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Enzymes and Coenzymes - Prostaglandin-Endoperoxide Synthases. According to news originating from Galveston, Texas, by NewsRx correspondents, research stated, "Cellular oxidative stress in the endothelium of blood vessels leads to several pathophysiological sequelae, including vascular damage and dysfunction, inflammation and atherosclerosis. Heme oxygenase-1 (HO-1) provides protection against oxidative stress-induced cell death and plays a crucial role in the regulation of cyclooxygenase-2 (COX-2) in endothelial cells."

Our news journalists obtained a quote from the research from the University of Texas Medical Branch, "In the present study, we have investigated the effects of bortezomib, a clinically used proteasome inhibitor, on the regulation of HO-1 and COX-2 in cultured human microvascular endothelial cells (HMECs). Bortezomib treatment of HMECS induced dose-and time-dependent expression of HO-1 and COX-2 mRNA and protein, and triggered nuclear translocation of nuclear factor erythroid 2-related transcription factor (Nrf2)."

According to the news editors, the research concluded: "These findings suggest that HO-1/COX-2-mediated induction of antioxidant mechanisms via Nrf2 activation may contribute to the cytoprotective effects of bortezomib in microvascular endothelium."

The news correspondents report that additional information may be obtained from S.K. Sahni, Univ Texas Med Branch, Inst Human Infect & Immun, Galveston, TX 77555, United States. Additional authors for this research include E.D. Thomasson, R. Shah and S.K. Sahni.

Researchers from University of Texas Southwestern Discuss Findings in Cardiology (Healthy aging does not compromise the augmentation of cardiac function during heat stress)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Cardiology have been published. According to news reporting out of Dallas, Texas, by NewsRx editors, research stated, "During heat stress, stroke volume is maintained in young adults despite reductions in cardiac filling pressures. This is achieved by a general augmentation of cardiac function, highlighted by a left and upward shift of the Frank-Starling relation."

Financial supporters for this research include HHS | National Institutes of Health (NIH), U.S. Department of Defense (DOD), American College of Sports Medicine Foundation.

Our news journalists obtained a quote from the research from the University of Texas Southwestern, "In contrast, healthy aged adults are unable to maintain stroke volume during heat stress. We hypothesized that this would be associated with a lack of shift in the Frank-Starling relation. Frank-Starling relations were examined in 11 aged [69 +/- 4 (SD) yr, 4 men/7 women] and 12 young (26 +/- 5 yr, 6 men/6 women) adults during normothermic and heat stress (1.5 degrees C increase in core temperature) conditions. During heat stress, increases in cardiac output were attenuated in aged adults (+ 2.5 +/- 0.3 (95% CI) vs. young: +4.5 +/- 0.5 l/min, P< 0.01) because of an attenuated chronotropic response (+ 30 +/- 4 vs. young: + 42 +/- 5 beats/min, P< 0.01). In contrast to our hypothesis, a leftward shift of the Frank-Starling relation maintained stroke volume during heat stress in aged adults (76 +/- 8 vs. normothermic: 74 +/- 8 ml, P = 0.38) despite reductions in cardiac filling pressure (6.6 +/- 1.1 mmHg, P< 0.01). In a subset of participants, volume loading was used to return cardiac filling pressure during heat stress to normothermic values, which resulted in a greater stroke volume for a given cardiac filling pressure in both groups."

According to the news editors, the research concluded: "These results demonstrate that the Frank-Starling relation shifts during heat stress in healthy young and aged adults, thereby preserving stroke volume despite reductions in cardiac filling pressures."

For more information on this research see: Healthy aging does not compromise the augmentation of cardiac function during heat stress. Journal of Applied Physiology, 2016;121 (4):885-892. Journal of Applied Physiology can be contacted at: Amer Physiological Soc, 9650 Rockville Pike, Bethesda, MD 20814, USA.

Researchers from University of Texas Southwestern Medical Center Report Recent Findings in Hypertension (Mechanisms and Treatment of Intradialytic Hypertension)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- New research on Cardiovascular Diseases and Conditions - Hypertension is the subject of a report. According to news reporting originating in Dallas, Texas, by NewsRx journalists, research stated, "Intradialytic hypertension is a condition where there is an increase in blood pressure (BP) from pre-to post-hemodialysis; this condition has been recently identified as an independent mortality risk factor in hypertensive hemodialysis patients. The mechanisms and management of intradialytic hypertension have been explored in numerous research studies over the past few years."

The news reporters obtained a quote from the research from the University of Texas Southwestern Medical Center, "Patients with intradialytic hypertension have been found to be more chronically volume overloaded compared to other hemodialysis patients, although no causal role has been established. Patients with intradialytic hypertension have intradialytic vascular resistance surges that likely explain the BP increase during dialysis. Acute intradialytic changes in endothelial cell function have been proposed as etiologies for the increase in vascular resistance, although it is unclear if endothelin-1 or some other vasoconstrictive peptide is responsible. There is an association between dialysate to serum sodium gradients and BP increase during dialysis in patients with intradialytic hypertension, although it is unclear if this is related to endothelial cell activity or acute osmolar changes. In addition to probing the dry weight of patients with intradialytic hypertension, other management strategies include lowering dialysate sodium and changing antihypertensives to include carvedilol or other poorly dialyzed antihypertensives. Hemodialysis patients with intradialytic hypertension have an increased mortality risk compared to patients with modest decreases in BP during dialysis. Intradialytic hypertension is associated with extracellular volume overload in addition to acute increases in vascular resistance during dialysis."

According to the news reporters, the research concluded: "Management strategies should include reevaluation of dry weight and modification of both the dialysate prescription and medication prescription."

Our news correspondents report that additional information may be obtained by contacting P.N. Van Buren, University of Texas Southwestern Medical Center, Dept. of Internal Medicine and Division of Nephrology, Dallas, TX, United States.

Researchers from University of Tokushima Report on Findings in Science (Novel human mutation and CRISPR/Cas genome-edited mice reveal the importance of C-terminal domain of MSX1 in tooth and palate development)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Science. According to news reporting originating in Tokushima, Japan, by NewsRx journalists, research stated, "Several mutations, located mainly in the MSX1 homeodomain, have been identified in non-syndromic tooth agenesis predominantly affecting premolars and third molars. We identified a novel frameshift mutation of the highly conserved C-terminal domain of MSX1, known as Msx homology domain 6 (MH6), in a Japanese family with non-syndromic tooth agenesis."

The news reporters obtained a quote from the research from the University of Tokushima, "To investigate the importance of MH6 in tooth development, Msx1 was targeted in mice with CRISPR/Cas system. Although heterozygous MH6 disruption did not alter craniofacial development, homozygous mice exhibited agenesis of lower incisors with or without cleft palate at E16.5. In addition, agenesis of the upper third molars and the lower second and third molars were observed in 4-week-old mutant mice. Although the upper second molars were present, they were abnormally small."

According to the news reporters, the research concluded: "These results suggest that the C-terminal domain of MSX1 is important for tooth and palate development, and demonstrate that CRISPR/Cas system can be used as a tool to assess causality of human disorders in vivo and to study the importance of conserved domains in genes."

For more information on this research see: Novel human mutation and CRISPR/Cas genome-edited mice reveal the importance of C-terminal domain of MSX1 in tooth and palate development. Scientific Reports, 2016;6():1-8. Scientific Reports can be contacted at: Nature Publishing Group, Macmillan Building, 4 Crinan St, London N1 9XW, England. Researchers from University of Tokyo Report Details of New Studies and Findings in the Area of Endometriosis (Resveratrol Enhances Apoptosis in Endometriotic Stromal Cells)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Fresh data on Uterine Diseases and Conditions - Endometriosis are presented in a new report. According to news originating from Bunkyo ku, Japan, by NewsRx correspondents, research stated, "Resistance to apoptosis, together with inflammatory and invasive activity, contributes to the pathogenesis of endometriosis; therefore, approaches that can safely enhance apoptosis in endometriotic tissue are highly sought after as a means of managing the disease. Although resveratrol (RVT) is known to induce apoptosis or increase sensitivity to apoptotic stimuli in various cancer cell types, its effect on human endometriosis has remained uncertain."

Funders for this research include Ministry of Health, Labor and Welfare, Ministry of Education, Culture, Sports, Science, and Technology.

Our news journalists obtained a quote from the research from the University of Tokyo, "This study aimed to investigate whether RVT induces or enhances apoptosis in human endometriotic stromal cells (ESCs). Endometriotic tissues were collected, during laparoscopies, from women affected by ovarian endometriosis. ESCs were prepared, cultured, and treated with RVT. Apoptosis was assessed by annexin V-PI staining. Survivin mRNA expression in ESCs was examined using RT-PCR. ESCs were pre-treated with or without RVT and then incubated with TNF-a-related-apoptosis-inducing ligand (TRAIL), which is a known pro-apoptotic molecule. RVT alone did not induce apoptosis in ESCs. RVT significantly reduced survivin mRNA expression (p <0.05). Pre-treatment with RVT significantly enhanced TRAIL-induced apoptosis (8.13 ? 0.83% (control) versus 29.19 ? 7.39% (pre-treated with RVT), p<0.05)."

According to the news editors, the research concluded: "This study indicates that RVT suppresses survivin expression and enhances TRAIL-induced apoptosis in ESCs."

The news correspondents report that additional information may be obtained from A. Taguchi, Dept. of Obstetrics and Gynecology, Faculty of Medicine, The University of Tokyo, Bunkyo-ku, Tokyo, Japan. Additional authors for this research include K. Koga, K. Kawana, T. Makabe, F. Sue, M. Miyashita, M. Yoshida, Y. Urata, G. Izumi, M. Tkamura, M. Harada, T. Hirata, Y. Hirota, O. Wada-Hiraike, T. Fujii and Y. Osuga.

Researchers from University of Tokyo Report Recent Findings in Science (Osmotic stress induces the phosphorylation of WNK4 Ser575 via the p38MAPK-MK pathway)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Data detailed on Science have been presented. According to news reporting from Bunkyo ku, Japan, by NewsRx journalists, research stated, "The With No lysine [K] (WNK)-Ste20-related proline/alanine-rich kinase (SPAK)/oxidative stress-responsive kinase 1 (OSR1) pathway has been reported to be a crucial signaling pathway for triggering pseudohypoaldosteronism type II (PHAII), an autosomal dominant hereditary disease that is characterized by hypertension. However, the molecular mechanism(s) by which the WNK-SPAK/OSR1 pathway is regulated remain unclear."

The news correspondents obtained a quote from the research from the University of Tokyo, "In this report, we identified WNK4 as an interacting partner of a recently identified MAP3K, apoptosis signal-regulating kinase 3 (ASK3). We found that WNK4 is phosphorylated in an ASK3 kinase activity-dependent manner. By exploring the ASK3-dependent phosphorylation sites, we identified Ser575 as a novel phosphorylation site in WNK4 by LC-MS/MS analysis. ASK3-dependent WNK4 Ser575 phosphorylation was mediated by the p38MAPK-MAPK-activated protein kinase (MK) pathway. Osmotic stress, as well as hypotonic low-chloride stimulation, increased WNK4 Ser575 phosphorylation via the p38MAPK-MK pathway. ASK3 was required for the p38MAPK activation induced by hypotonic stimulation but was not required for that induced by hypertonic stimulation or hypotonic low-chloride stimulation."

According to the news reporters, the research concluded: "Our results suggest that the p38MAPK-MK pathway might regulate WNK4 in an osmotic stress-dependent manner but its upstream regulators might be divergent depending on the types of osmotic stimuli."

For more information on this research see: Osmotic stress induces the phosphorylation of WNK4 Ser575 via the p38MAPK-MK pathway. Scientific Reports, 2016;6 ():18710. (Nature Publishing Group - www.nature.com/; Scientific Reports - www.nature.com/srep/)

Our news journalists report that additional information may be obtained by contacting J. Researchers from University of Tokyo School of Medicine Describe Findings in Blood Coagulation Factor Inhibitors (Fli1 deficiency contributes to the downregulation of endothelial protein C receptor in systemic sclerosis: a possible role in ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Current study results on Hematology - Blood Coagulation Factor Inhibitors have been published. According to news reporting originating in Bunkyo ku, Japan, by NewsRx journalists, research stated, "Endothelial protein C receptor (EPCR), expressed predominantly on endothelial cells, plays a critical role in the regulation of the coagulation system and also mediates various cytoprotective effects by binding and activating protein C. So far, the role of EPCR has not been studied in systemic sclerosis (SSc)."

Financial supporters for this research include Ministry of Health, Labour and Welfare, Actelion Pharmaceuticals.

The news reporters obtained a quote from the research from the University of Tokyo School of Medicine, "To investigate the potential contribution of EPCR to the development of SSc. EPCR expression was examined in skin samples and cultivated dermal microvascular endothelial cells by immunostaining, immunoblotting and/or quantitative reverse-transcription polymerase chain reaction. Fli1, binding to the PROCR promoter, was assessed by chromatin immunoprecipitation. Serum EPCR levels were determined by enzyme-linked immunosorbent assay in 65 patients with SSc and 20 healthy subjects. EPCR expression was decreased in dermal small vessels of SSc lesional skin compared with those of healthy control skin. Transcription factor Fli1, deficiency of which is implicated in SSc vasculopathy, occupied the PROCR promoter, and EPCR expression was suppressed in Fli1 small interfering RNA-treated endothelial cells and dermal small vessels of Fli1(plusminus) mice. In patients with SSc, decreased serum EPCR levels were associated with diffuse skin involvement, interstitial lung disease and digital ulcers. Furthermore, serum EPCR levels inversely correlated with plasma levels of plasmin-a2-plasmin inhibitor complex (PIC). Importantly, bosentan significantly reversed circulating EPCR and PIC levels in patients with SSc, and the expression of Fli1 and EPCR in dermal small vessels was elevated in patients treated with bosentan compared with untreated patients."

According to the news reporters, the research concluded: "Endothelial EPCR downregulation due to Fli1 deficiency may contribute to hypercoagulation status leading to tissue fibrosis and impaired peripheral circulation in SSc."

Our news correspondents report that additional information may be obtained by contacting R. Saigusa, Dept. of Dermatology, University of Tokyo Graduate School of Medicine, 7-3-1 Hongo, Bunkyo-ku, Tokyo, 113-8655, Japan. Additional authors for this
Oncology - Breast Cancer

Researchers from University of Toronto Describe Findings in Breast Cancer (Modelling mammography screening for breast cancer in the Canadian context: Modification and testing of a microsimulation model)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Research findings on Oncology - Breast Cancer are discussed in a new report. According to news reporting out of Toronto, Canada, by NewsRx editors, research stated, "Modelling is a flexible and efficient approach to gaining insight into the trade-offs surrounding a complex process like breast screening, which involves more variables than can be controlled in an experimental study. Data and methods: The University of Wisconsin Cancer Intervention and Surveillance Modeling Network (CISNET) breast cancer microsimulation model was adapted to simulate breast cancer incidence and screening performance in Canada."

Our news journalists obtained a quote from the research from the University of Toronto, "The model considered effects of breast density on the sensitivity and specificity of screening. The model's ability to predict age-specific incidence of breast cancer was assessed. Predictions of age-adjusted incidence over calendar years and age-specific incidence of breast cancer in Canadian women are presented. Based on standard screening strategies, ratios of in situ to invasive disease and stage distribution of disease at diagnosis are compared with data from the British Columbia provincial screening program. The adapted model performs well in predicting age-specific incidence and cross-sectional incidence in the absence of screening."

According to the news editors, the research concluded: "The ratios of detection of in situ to invasive cancers and the overall stage distribution of detected cancers are in reasonable agreement with empirical data from British Columbia."

For more information on this research see: Modelling mammography screening for breast cancer in the Canadian context: Modification and testing of a microsimulation model. Health Reports, 2015;26(12):3-8. Health Reports can be contacted at: Statistics Canada, 100 Tunneys Pasture Driveway, Ottawa, Ontario K1A 0T6, Canada.

Our news journalists report that additional information may be obtained by contacting M.J. Yaffe, University of Toronto, Dept. of Med Imaging, Toronto, ON M5S 1A1, Canada. Additional authors for this research include N. Mittmann, P. Lee, A.N.A. Tosteson, A. Trentham-Dietz, O. Alagoz and N.K. Stout.

Researchers from University of Toronto Detail New Studies and Findings in the Area of Hypertrophic Cardiomyopathy (Myocardial Dimensions in Children With Hypertrophic Cardiomyopathy: A Comparison Between Echocardiography and Cardiac Magnetic ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Heart Disorders and Diseases - Hypertrophic Cardiomyopathy. According to news reporting from Toronto, Canada, by NewsRx journalists, research stated, "The primary mode of imaging in hypertrophic cardiomyopathy (HCM) is transthoracic echocardiography (TTE). However, in adults inadequate acoustic windows lead to poor quantification of myocardial thickness compared with cardiac magnetic resonance (CMR) imaging."

The news correspondents obtained a quote from the research from the University of Toronto, "In comparison, children have better acoustic windows and TTE measurements of wall thickness might be more accurate. The aim of this study was to assess the performance of TTE compared with CMR for the assessment of myocardial thickness in children with HCM. Nineteen children (median age, 12.7 years; range, 8.4-18.4 years) with known HCM were studied using TTE and CMR imaging on the same day. The left ventricle was measured off-line using the standard 16-segment model. With CMR imaging 304 (19 x 16) segments were analyzable whereas only 263 were analyzable using echocardiography. Wall thickness measurements according to TTE were greater than those according to CMR imaging in the basal anterolateral, midventricular anterior and anterolateral and apical inferior, lateral and septal segments and smaller for the midventricular inferior and inferoseptal segments. Reproducibility of CMR and TTE measurements was assessed using the intraclass correlation coefficient (ICC). CMR measurements showed excellent intrareader (ICC, 0.929-0.991) and moderate inter-reader (ICC range, 0.512-0.991) reproducibility. TTE measurements revealed moderate intrareader (ICC, 0.575-0.942) and poor inter-reader (ICC range, -1.02 to 0.939) reproducibility. Echocardiography incompletely assesses circumferential myocardial thickness in a proportion of pediatric patients with HCM. Echocardiography under-and overestimates maximum wall thickness compared with CMR, depending on the location."

According to the news reporters, the research concluded: "Measurements using CMR are more reproducible than those obtained using echocardiography."

Our news journalists report that additional information may be obtained by contacting L. Grosse-Wortmann, University of Toronto, Hospital for Sick Children, Dept. of Diagnost Imaging, Toronto, ON, Canada. Additional authors for this research include A. Dragelescu, L. Benson, J. Forsey, M. Shariat, S.J. Yoo, L. Mertens, D. Wong and L. Grosse-
Researchers from University of Toulouse Detail New Studies and Findings in the Area of Acute Myeloid Leukemia (Prognostic impact of viral reactivations in acute myeloid leukemia patients undergoing allogeneic stem cell transplantation in first ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A new study on Oncology - Acute Myeloid Leukemia is now available. According to news reporting originating from Toulouse, France, by NewsRx correspondents, research stated, "Cytomegalovirus (CMV) serological status of donor and recipient as well as CMV reactivation have been associated with a lower risk of relapse in acute myeloid leukemia (AML) patients after allogeneic stem cell transplantation (alloSCT). Since immunosuppression following transplant allows resurgence of many other viruses, we retrospectively evaluated the impact of viral reactivations on relapse and survival in a cohort of 136 AML patients undergoing alloSCT in first remission from sibling (68%) or unrelated (32%) donors."

Our news editors obtained a quote from the research from the University of Toulouse, "Myeloablative and reduced-intensity conditioning regimen were given to 71 and 65 patients, respectively. Including CMV reactivations, at least 1 viral reactivation was recorded in 76 patients. Viral reactivations were associated with a lower risk of relapse (adjusted HR 0.14; 95% CI 0.07-0.30; P< 0.01), better disease-free survival (aHR 0.29; 95% CI 0.16-0.54; P< 0.01) but higher non relapse mortality. This translated into a better overall survival (aHR 0.44; 95%CI 0.25-0.77; P< 0.01) in patients who experienced viral reactivation. Thus, viral reactivations, including but not limited to CMV reactivation, are associated with a better outcome particularly with regard to the risk of relapse in AML patients undergoing alloSCT."

According to the news editors, the research concluded: "New guidelines regarding the choice of donor according to the CMV serostatus are needed."

Researchers from University of Trieste Provide Details of New Studies and Findings in the Area of Liver Cancer (Rapid and cost-effective xenograft hepatocellular carcinoma model in Zebrafish for drug testing)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Oncology - Liver Cancer. According to news reporting out of Trieste, Italy, by NewsRx editors, research stated, "We developed a novel, rapid and cost-effective Zebrafish xenograft model of hepatocellular carcinoma (HCC) for drug screening in the disease. Following injection into the yolk sack of Zebrafish larvae of the human HCC cell line JHH6 stained by a vital dye, tumor mass growth was followed by fluorescence microscopy and by human Ki67 quantification."

Financial supporters for this research include “Fondazione Benefica Kathleen Foreman Casali of Trieste”, “Beneficentia Stiftung” of Vaduz Liechtenstein, Italian Minister of Instruction, University and Research (MIUR).

Our news journalists obtained a quote from the research from the University of Trieste, "Tumor induced neo-angiogenesis was evaluated by alkaline phosphatase staining of the vessels, by using the Tg(fli1: EGFP) y(1) strain of Zebrafish and by the quantification of the zebrafish vascular endothelial growth factor and of its receptor. We show that it is feasible to micro-inject JHH6 in Zebrafish larvae, that injected cells can grow for different days and that this induces a marked neo-angiogenesis. Finally, we show that our model allows testing the effects of anti-HCC drugs such as Bortezomib. Compared to more complex HCC mouse models, our model is far less expensive, faster to set up and does not need immunosuppressant treatment. Finally, the model makes use of JHH6, an aggressive form of HCC cell line never tested before in Zebrafish."

According to the news editors, the research concluded: "The possibility to test anti HCC/neo-angiogenesis drugs makes our JHH6 model useful to select therapeutic molecules for a highly vascularized tumor such as HCC."

Our news journalists report that additional information may be obtained by contacting G. Grassi, University of Trieste, Dept. of Life Sci, I-34127 Trieste, Italy. Additional authors for this research include C. Zennaro, B. Dapas, M. Carraro, M. Mariotti and G. Grassi. The direct object identifier (DOI) for that additional information is:
Researchers from University of Tunis Detail New Studies and Findings in the Area of Venoms (Lebein, a snake venom disintegrin, suppresses human colon cancer cells proliferation and tumor-induced angiogenesis through cell cycle arrest, apoptosis ...)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Biological Factors - Venoms. According to news reporting originating in Tunis, Tunisia, by NewsRx journalists, research stated, "Lebein, is an heterodimeric disintegrin isolated from Macrovipera lebetina snake venom that was previously characterized as an inhibitor of ADP-induced platelet aggregation. In this study, we investigated the effect of Lebein on the p53-dependent growth of human colon adenocarcinoma cell lines."

The news reporters obtained a quote from the research from the University of Tunis, "We found that Lebein significantly inhibited LS174 (p53wt), HCT116 (p53wt), and HT29 (p53mut) colon cancer cell viability by inducing cell cycle arrest through the modulation of expression levels of the tumor suppression factor p53, cell cycle regulating proteins cyclin D1, CDK2, CDK4, retinoblastoma (Rb), CDK1, and cyclin-dependent kinase inhibitors p21 and p27. Interestingly, Lebein-induced apoptosis of colon cancer cells was dependent on their p53 status. Thus, in LS174 cells, cell death was associated with PARP cleavage and the activation of caspases 3 and 8 while in HCT116 cells, Lebein induced caspase-independent apoptosis through increased expression of apoptosis inducing factor (AIF). In LS174 cells, Lebein triggers the activation of the MAPK ERK1/2 pathway through induction of reactive oxygen species (ROS). It also decreased cell adhesion and migration to fibronectin through down regulation of 51 integrin. Moreover, Lebein significantly reduced the expression of two angiogenesis stimulators, Vascular Endothelial Growth Factor (VEGF) and Neuropilin 1 (NRP1). It inhibited the VEGF-induced neovascularization process in the quail embryonic CAM system and blocked the development of human colon adenocarcinoma in nude mice."

According to the news reporters, the research concluded: "Overall, our work indicates that Lebein may be useful to design a new therapy against colon cancer."

Our news correspondents report that additional information may be obtained by
Researchers from University of Turin Report Details of New Studies and Findings in the Area of Dihydroxyphenylalanine (Peripheral neuropathy associated with levodopa-carbidopa intestinal infusion: a long-term prospective assessment)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators publish new report on Dihydroxyphenylalanine. According to news originating from Torino, Italy, by NewsRx correspondents, research stated, "Subacute and chronic peripheral neuropathies (PNP) have been reported in Parkinson's disease (PD) patients treated with levodopa/carbidopa intestinal gel infusion (LCIG), although several aspects of their incidence and pathogenesis still remain to be clarified. This study main objective is to prospectively report the 2-year incidence of PNP in patients treated with LCIG."

Financial support for this research came from Neurology Unit staff of San Giovanni Battista Hospital, Turin.

Our news journalists obtained a quote from the research from the University of Turin, "The clinical, hematological, nutritional and electrophysiological assessments of 33 consecutive patients have been prospectively collected and evaluated. At baseline (before the start of LCIG therapy), 3/33 (9%) patients showed symptomatic PNP and 7/33 (21%) subclinical PNP. During a follow-up of 24.36 ± 12.18 months, 2/23 patients with normal baseline clinical-electrophysiological assessment developed a subacute PNP, 2/23 developed a chronic PNP and 7/23 developed a subclinical PNP. LCIG was immediately halted in the subacute cases, while the infusion therapy was not interrupted in chronic and subclinical forms. All PNP were supplemented with vitamin B1 and B12, showing a clinical improvement and/or substantial stability at the following evaluations. Higher levodopa-equivalent daily dose (P: 0.024) and homocysteine levels (P: 0.041) were found in chronic PNP, while no correlations were observed with vitamin B12, folate and UPDRS values. A trend towards BMI reduction was observed in both PNP and unaffected subjects and one patient developed a symptomatic PNP associated with a relevant weight loss. Serial clinical-electrophysiological evaluations are mandatory in patients treated with LCIG, given the possible risk of subacute and chronic PNP."

According to the news editors, the research concluded: "No clear causative factors has been recognized in the subacute forms, whilst homocysteine-mediated neurotoxicity seems to underlie the pathogenesis of chronic forms."

For more information on this research see: Peripheral neuropathy associated with levodopa-carbidopa intestinal infusion: a long-term prospective assessment. European Journal
Researchers from University of Ulm Report on Findings in Prostate Cancer (Prognostic Factors for Biochemical Recurrence More than 10 Years after Radical Prostatectomy)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Investigators discuss new findings in Oncology - Prostate Cancer. According to news reporting originating from Ulm, Germany, by NewsRx correspondents, research stated, "Some patients with long postoperative intervals of undetectable prostate specific antigen are still at risk for biochemical recurrence. Our aims were to identify prognostic factors for late biochemical recurrence, including cancer family history, and evaluate cancer specific mortality."

Our news editors obtained a quote from the research from the University of Ulm, "We identified 10,310 patients after radical prostatectomy without neoadjuvant or adjuvant therapy between 1979 and 2015 in the prospective German Familial Prostate Cancer database. A subgroup of 2,480 patients with more than 10 years of followup (median 12.8) had undetectable prostate specific antigen. Biochemical recurrence, defined as prostate specific antigen 0.2 ng/ml or greater, developing at more than 10 years was defined as late biochemical recurrence. Multiple proportional hazards regression with forward selection was applied to determine prognostic factors for late biochemical recurrence. The Kaplan-Meier estimated biochemical recurrence rate at 10, 15 and 20 years was 34.3%, 44.0% and 52.7%, respectively. Of 2,480 patients with undetectable prostate specific antigen 10 years postoperatively 249 subsequently had biochemical recurrence, of whom 12 died of prostate cancer. The factors associated with late biochemical recurrence were age at surgery (HR 1.04 per year, p = 0.027), prostate specific antigen at diagnosis (HR 1.02 per ng/ml, p = 0.020), pathological Gleason score (categorical 2-6 vs 7 [ 3 + 4], 7, 7 [ 4 + 3] and 8-10, p = 0.002) and pathological tumor stage pT3a or greater (HR 1.50, p = 0.065). From years 10 to 15 and 10 to 20 postoperatively the biochemical recurrence rate increased by 9.7% and 18.4%, respectively. In contrast to a family history of prostate cancer, age at surgery, prostate specific antigen at diagnosis, pathological tumor stage and pathological Gleason score were prognostic factors for late biochemical recurrence."
According to the news editors, the research concluded: "Patients with late biochemical recurrence are still at risk for death from prostate cancer."

Researchers from University of Ulsan Detail New Studies and Findings in the Area of Enzyme Replacement Therapy (Long-term enzyme replacement therapy for Fabry disease: efficacy and unmet needs in cardiac and renal outcomes)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Researchers detail new data in Drugs and Therapies - Enzyme Replacement Therapy. According to news reporting out of Seoul, South Korea, by NewsRx editors, research stated, "Fabry disease is a progressive lysosomal storage disease caused by alpha-galactosidase A deficiency. This condition is characterized by progressive accumulation of glycosphingolipids with functional impairment in various organs, including the kidney, heart and cerebrovascular system."

Our news journalists obtained a quote from the research from the University of Ulsan, "Enzyme replacement therapy (ERT) is essential because it attenuates the disease progression. The present study investigated the long-term efficacy of ERT in 19 Korean Fabry patients (11 adult males, 4 symptomatic female carriers and 4 pediatric males) who had received ERT for 8.1 +/- 2.2 years (range, 5.3-10.5 years). In the 11 adult males, the mean reduction in the estimated glomerular filtration rate (eGFR) was -3.8 +/- 4.5 ml(-1) min 1.73 m(-2). The rate of eGFR decline was significantly lower in patients with lower proteinuria (<1 g per day) before ERT. The left ventricular mass index decreased or was stable throughout the ERT in male patients with or without left ventricular hypertrophy before ERT initiation. In female carriers and pediatric male patients, renal and cardiac functions remained stable with ERT. Arrhythmias were observed in 10 adult males and 1 female patient before ERT and persisted during ERT."
One pediatric patient newly developed arrhythmia despite ERT."

According to the news editors, the research concluded: "Long-term ERT has beneficial effects on the renal and cardiac outcomes of Fabry patients but has limited effect in patients with irreversible organ damage. Identification of patients in the early disease stage and rapid ERT initiation might be the best strategy to improve the natural course of the disease."
