In addition to the background information obtained for this patent, NewsRx journalists also obtained the inventors' summary information for this patent: "The present invention provides the use of 1-octene as a unique breath biomarker for lung cancer. The present invention further provides a system and methods for diagnosing, monitoring or prognosing lung cancer or differentiating between benign and malignant solitary pulmonary nodules, small cell and non-small cell lung cancer, adenocarcinoma and squamous cell carcinoma, and early and advanced stage lung cancer. The system and methods of the present invention can be used for predicting the responses to anti-cancer therapy (classical chemotherapy and/or targeted therapy).

"The present invention is based in part on the unexpected finding of a unique profile of
"VOCs for diagnosing lung cancer and the identification of 1-octene as a novel breath biomarker for lung cancer. Surprisingly, the use of a sensor array comprising at least one sensor comprising a random network of carbon nanotubes coated with polycyclic aromatic hydrocarbons and at least one sensor comprising film/assembly of metal nanoparticles coated with an organic coating, preferably thiols, in conjunction with a pattern recognition algorithm afforded the differentiation between benign and malignant solitary pulmonary nodules, small cell and non-small cell lung cancer, adenocarcinoma and squamous cell carcinoma, and early and advanced stage lung cancer.

"According to a first aspect, the present invention provides a set of volatile organic compounds as breath biomarkers for lung cancer, wherein the set comprises 1-octene.

"According to another aspect, the present invention provides a method of diagnosing, monitoring or prognosing lung cancer in a subject or predicting a patient's response to a treatment regimen, the method comprising the steps of: a) collecting a test breath sample from a test subject; b) determining the level of at least one volatile organic compound from a set of volatile organic compounds in the test sample, wherein the set of volatile organic compounds comprises 1-octene; and c) comparing the level of the at least one volatile organic compound from the test sample with the level of said at least one volatile organic compound in a control sample, whereby a significantly different level of said at least one volatile organic compound in the test sample as compared to the level of said compound in the control sample is indicative of lung cancer or provides the prediction of a patient's response to a treatment regimen.

"In one embodiment, the level of the at least one volatile organic compound in the test sample is increased as compared with the level of said compound in the control sample.

"In another embodiment, the level of the at least one volatile organic compound in the test sample is decreased as compared with the level of said compound in the control sample.

"In particular embodiments, the levels of a plurality of volatile organic compounds in the breath sample from a lung cancer patient form a pattern which is significantly different from the pattern of said volatile organic compounds in the control sample. According to further embodiments, the pattern is significantly different from a predetermined pattern of occurrence of volatile organic compounds in breath samples.

"According to various embodiments, the control sample may be obtained from a reference group comprising subjects that are not afflicted with lung cancer (negative control). In alternative embodiments, the control sample may be obtained from a population of patients known to be afflicted with lung cancer (positive control). The control sample, according to the principles of the present invention is obtained from at least one subject, preferably a plurality of subjects. A set of control samples may be stored as a reference collection of data.

"According to some embodiments, the step of determining the levels of volatile organic compounds in a sample comprises the use of at least one technique selected from the group consisting of Gas-Chromatography (GC), GC-lined Mass-Spectrometry (GC-MS), Proton Transfer Reaction Mass-Spectrometry (PTR-MS), Electronic nose device, and Quartz Crystal Microbalance (QCM). Each possibility represents a separate embodiment of the present invention.

"In a particular embodiment, the step of determining the levels of volatile organic compounds in a sample further comprises the use of a breath concentrator.

"In an exemplary embodiment, the step of determining the levels of volatile organic compounds in a sample comprises the use of Gas-Chromatography-Mass Spectrometry (GC-MS) combined with solid phase microextraction (SPME).

"In specific embodiments, solid phase microextraction comprises the use of extraction fibers coated with at least one polymer selected from the group consisting of
divinylbenzene, carboxen, polydimethylsiloxane and combinations thereof. Each possibility represents a separate embodiment of the present invention.

"In various embodiments, the test subject is selected from a subject who is at risk of developing lung cancer, a subject who is suspected of having lung cancer, and a subject who is afflicted with lung cancer. Each possibility represents a separate embodiment of the present invention.

"According to yet another aspect, the present invention provides a system for diagnosing, monitoring or prognosing lung cancer or stages or subtypes thereof in a subject or predicting a patient's response to a treatment regimen, the system comprising: (a) an apparatus comprising at least one sensor comprising single walled carbon nanotubes coated with polycyclic aromatic hydrocarbons, and at least one sensor comprising metal nanoparticles coated with an organic coating; (b) a detection means; and (c) a processing unit comprising a pattern recognition analyzer, wherein the pattern recognition analyzer receives sensor output signals and compares them to stored data so as to enable the diagnosis, monitoring or prognosis of lung cancer or stages or subtypes thereof or the prediction of a patient's response to a treatment regimen.

"In some embodiments, the polycyclic aromatic hydrocarbons are selected from arenes, polyarenes, and combinations thereof. Each possibility represents a separate embodiment of the present invention. In certain embodiments, the arenes or polyarenes are selected from the group consisting of naphthalene, acenaphthene, anthracene, phenanthrene, pyrene, benzo[a]pyrene, chrysene, fluoranthene, C_{18}-C_{180} graphenes and combinations thereof. Each possibility represents a separate embodiment of the present invention. In specific embodiments, the arenes or polyarenes are C_{18}-C_{180} graphenes, for example C_{42} graphene, C_{50} graphene and the like.

"In various embodiments, the arenes or polyarenes are substituted with hydrophobic or hydrophilic carbon chains and/or at least one functional group selected from the group consisting of ester, ether, alcohol, amine, imine, amide, ammonium, keto, aldehyde, halogen (halo), pyridyl, phosphate, thiol, sulfonate, sulfonyl, hydroxyl, carboxylate, carboxyl, and carbonate groups. Each possibility represents a separate embodiment of the present invention.

"In particular embodiments, the polycyclic aromatic hydrocarbons comprise hexa-peri-hexabenzocoronene (HBC) molecules, which are unsubstituted or substituted by any one of 2-ethyl-hexyl (HBC-C_{6,2}), 2-hexyldecane (HBC-C_{10,6}), 2-decyl tetradecane (HBC-C_{14,10}), and dodecane (HBC-C_{12}). Each possibility represents a separate embodiment of the present invention.

"In another embodiment, the single walled carbon nanotubes are organized in a random network configuration. In other embodiments, the single walled carbon nanotubes have diameters ranging from about 0.9 nanometer to about 5 nanometers, and lengths ranging from about 1 micrometer to about 50 micrometers.

"In further embodiments, the metal nanoparticles are selected from the group consisting of Au, Ag, Ni, Co, Pt, Pd, Cu, and Al nanoparticles and combinations thereof. Each possibility represents a separate embodiment of the present invention. In an exemplary embodiment, the metal nanoparticles are gold (Au) nanoparticles.

"In some embodiments, the organic coating of the metal nanoparticles comprises compounds selected from the group consisting of alkylthiols, arylthiols, alkylarylthiols, arylthiolates, omega-functionalized alkanethiolates, arenethiolates, (gamma-mercaptopropyl) tri-methyloxyisilane, dialkyl disulfides and combinations and derivatives thereof. Each possibility represents a separate embodiment of the present invention.

"In certain embodiments, the organic coating of the metal nanoparticles comprises
thiols.

"In particular embodiments, the organic coating of the metal nanoparticles comprises compounds selected from the group consisting of hexanethiol, 2-ethylhexanethiol, 3-methyl-1-butane thiol, octadecylamine, decanethiol, dodecanethiol, 2-mercaptobenzoxazole, 4-methoxy-tolu enethiol, tert-dodecanethiol, 2-amino-4-chlorobenzenethiol, 2-mercaptobenzimidazole, benzylmercaptan, 2-nitro-4-trifluoro-methylbenzenethiol, 2-naphthalenethiol, 2-nitro-4 trifluoro-methylbenzenethiol, and combinations thereof. Each possibility represents a separate embodiment of the present invention.

"In other embodiments, the metal nanoparticles have a morphology selected from a cubic, a spherical, and a spheroidal morphology. Each possibility represents a separate embodiment of the present invention.

"In certain embodiments, the at least one sensor is configured in a form selected from the group consisting of a capacitive sensor, a resistive sensor, a chemoresistive sensor, an impedance sensor, and a field effect transistor sensor. Each possibility represents a separate embodiment of the present invention.

"In some embodiments, the system comprises between 2 and 20 sensors, for example 8 sensors, 13 sensors, 18 sensors and the like. In other embodiments, the detection means comprises a device for measuring changes in resistance, conductance, alternating current (AC), frequency, capacitance, impedance, inductance, mobility, electrical potential, optical property or voltage threshold. Each possibility represents a separate embodiment of the present invention.

"In a further aspect, the present invention provides a method of diagnosing, monitoring or prognosing lung cancer or stages or subtypes thereof in a subject or predicting a patient's response to a treatment regimen, the method comprising the steps of: (a) providing a system comprising an apparatus comprising at least one sensor comprising single walled carbon nanotubes coated with polycyclic aromatic hydrocarbons, and at least one sensor comprising metal nanoparticles coated with an organic coating; a detection means; and a processing unit comprising a pattern recognition analyzer comprising at least one pattern recognition algorithm; (b) exposing the apparatus to a test exhaled breath sample; (c) measuring at least one response induced parameter from the apparatus upon exposure to the test sample to obtain a response pattern; and (d) analyzing the response pattern obtained in step (c) using a pattern recognition algorithm by comparing it to stored data obtained from a control sample whereby a significantly different response pattern of the test sample as compared the control sample is indicative of lung cancer or stages or subtypes thereof or provides the prediction of a patient's response to a treatment regimen.

"In some embodiments, the method of diagnosing, monitoring or prognosing lung cancer or stages or subtypes thereof in a subject or predicting a patient's response to a treatment regimen further enables the differentiation between subjects having benign solitary pulmonary nodules and subjects having malignant solitary pulmonary nodules. In other embodiments, the method enables the differentiation between subjects having small cell lung cancer and subjects having non-small cell lung cancer, and further enables the differentiation between subjects having non-small cell lung cancer in an early stage and subjects having non-small cell lung cancer in an advanced stage. In additional embodiments, the method enables the differentiation between subjects having adenocarcinoma and subjects having squamous cell carcinoma. In further embodiments, the method enables the differentiation between subjects having lung cancer and subjects having lung metastases.

"In certain embodiments, the method of diagnosing, monitoring or prognosing lung cancer or stages or subtypes thereof in a subject or predicting a patient's response to a treatment regimen is directed to prognosing a subject who is suspected of having lung cancer.
"In other embodiments, the method is directed to a subject having malignant solitary pulmonary nodules.

"The detected pattern can be analyzed using a pattern recognition analyzer which utilizes at least one pattern recognition algorithm. Suitable pattern recognition algorithms include, but are not limited to, artificial neural networks, multi-layer perceptron (MLP), generalized regression neural network (GRNN), fuzzy inference systems (FIS), self-organizing map (SOM), radial bias function (RBF), genetic algorithms (GAS), neuro-fuzzy systems (NFS), adaptive resonance theory (ART) and statistical methods including, but not limited to, principal component analysis (PCA), partial least squares (PLS), multiple linear regression (MLR), principal component regression (PCR), discriminant function analysis (DFA) including linear discriminant analysis (LDA), and cluster analysis including nearest neighbor. Each possibility represents a separate embodiment of the present invention. In an exemplary embodiment, the algorithm used to analyze the pattern is discriminant factor analysis (DFA).

"In certain embodiments, the response pattern is formed by the sensors detection of at least one volatile biomarker which is indicative of lung cancer or stages or subtypes thereof. In particular embodiments, the at least one volatile biomarker which is indicative of lung cancer or stages or subtypes thereof is 1-octene.

"In various embodiments, the test subject is a mammal, preferably a human.

"Further embodiments and the full scope of applicability of the present invention will become apparent from the detailed description given hereinafter. However, it should be understood that the detailed description and specific examples, while indicating preferred embodiments of the invention, are given by way of illustration only, since various changes and modifications within the spirit and scope of the invention will become apparent to those skilled in the art from this detailed description."

Our reports deliver fact-based news of research and discoveries from around the world. Copyright 2017, NewsRx LLC
Patent number 9526800 is assigned to Massachusetts Institute of Technology (Cambridge, MA).

The following quote was obtained by the news editors from the background information supplied by the inventors: "Despite extensive study, cancer, and particularly the process of metastasis, remain major causes of illness and mortality. Prior indications suggest that changes in extracellular matrix (ECM) proteins may play significant roles in cancer progression and metastasis. The field of proteomics involves the study of proteins in complex physiological systems and their role in these systems. Large data sets have been generated using genomic and proteomic methods, but the use of that information to identify the role of extracellular matrix (ECM) proteins in disease has been limited. This is because the ECM is insoluble and crosslinked and its composition has been difficult to determine."

In addition to the background information obtained for this patent, NewsRx journalists also obtained the inventors' summary information for this patent: "The invention in some aspects is a method involving administering to a subject having a tumor a binding reagent which interacts specifically with an extracellular matrix (ECM) protein, wherein the binding reagent is conjugated to an active agent in an effective amount to deliver the active agent to the tumor. The active agent may be or include a detectable label or a chemotherapeutic agent. The tumor may be, in some embodiments, metastatic.

"In some embodiments the ECM protein is a protein selected from an ECM protein signature characteristic of non-metastatic mammary carcinoma, an ECM protein signature characteristic of metastatic mammary carcinoma, an ECM protein signature characteristic of mammary carcinoma, an ECM protein signature characteristic of metastatic primary colon carcinoma, an ECM protein signature characteristic of colon carcinoma metastases, an ECM protein signature characteristic of metastatic colon carcinoma (primary & secondary), and an ECM protein signature whose expression is associated with colon cancer or metastatic colon cancer.

"In other embodiments the ECM protein is an ECM protein characteristic of metastatic tumors and is selected from an ECM protein signature characteristic of metastatic mammary carcinoma, an ECM protein signature characteristic of metastatic primary colon carcinoma, an ECM protein signature characteristic of colon carcinoma metastases, an ECM protein signature characteristic of metastatic colon carcinoma (primary & secondary), and an ECM protein signature whose expression is associated with colon cancer or metastatic colon cancer.

"The binding reagent in other embodiments is an antibody or an antibody fragment. The tumor in some embodiments is a tumor of the breast. The ECM protein may be selected from an ECM protein signature characteristic of metastatic mammary carcinoma. In some embodiments the ECM protein signature characteristic of metastatic mammary carcinoma is selected from subgroup 2A, subgroup 2B, and subgroup 2C.

"In other embodiments the ECM protein is selected from an ECM protein signature characteristic of non-metastatic mammary carcinoma. In some embodiments the ECM protein signature characteristic of non-metastatic mammary carcinoma is a protein selected from subgroup 1A, subgroup 1B, and subgroup 1C.

"In some embodiments the ECM protein is a selected from an ECM protein signature characteristic of mammary carcinoma. In other embodiments the ECM protein signature characteristic of mammary carcinoma is a protein selected from subgroup 3A, subgroup 3B, and subgroup 3C.

"The tumor may be a tumor of the colon. In some embodiments the ECM protein is
selected from an ECM protein signature characteristic of metastatic primary colon carcinoma. In other embodiments the ECM protein signature characteristic of metastatic primary colon carcinoma is a protein selected from subgroup 4A, subgroup 4B, and subgroup 4C. In yet other embodiments the ECM protein is selected from an ECM protein signature characteristic of colon carcinoma metastases and optionally the ECM protein signature characteristic of colon carcinoma metastases is a protein selected from subgroup 5A, subgroup 5B, and subgroup 5C. The ECM protein in other embodiments is selected from an ECM protein signature characteristic of metastatic colon carcinoma (primary & secondary). In some embodiments the ECM protein signature characteristic of metastatic colon carcinoma (primary & secondary) is a protein selected from subgroup 6A, subgroup 6B, and subgroup 6C. In yet other embodiments the ECM protein is selected from an ECM protein signature whose expression is associated with colon cancer or metastatic colon cancer. In some embodiments the ECM protein whose expression is associated with colon cancer or metastatic colon cancer is a protein selected from subgroup 7A, subgroup 7B, and subgroup 7C.

"A composition of a binding reagent which interacts specifically with an extracellular matrix (ECM) protein, wherein the binding reagent is conjugated to an active agent is provided according to other aspects of the invention. The ECM protein may be a protein characteristic of cancers. In some embodiments the binding reagent is an antibody, and optionally is selected from the group consisting of a monoclonal antibody, a polyclonal antibody, a chimeric antibody, a humanized antibody, a human antibody, and an antibody fragment. In some embodiments the active agent is a detectable label or a chemotherapeutic agent.

"In other embodiments the ECM protein is selected from an ECM protein signature characteristic of metastatic mammary carcinoma. In some embodiments the ECM protein signature characteristic of metastatic mammary carcinoma is selected from subgroup 2A, subgroup 2B, and subgroup 2C. In other embodiments the ECM protein is selected from an ECM protein signature characteristic of non-metastatic mammary carcinoma. In some embodiments the ECM protein signature characteristic of non-metastatic mammary carcinoma is a protein selected from subgroup 1A, subgroup 1B, and subgroup 1C. The ECM protein is selected from an ECM protein signature characteristic of mammary carcinoma in some embodiments. In other embodiments the ECM protein signature characteristic of mammary carcinoma is a protein selected from subgroup 3A, subgroup 3B, and subgroup 3C.

"The ECM protein is selected from an ECM protein signature characteristic of metastatic primary colon carcinoma. In some embodiments the ECM protein signature characteristic of metastatic primary colon carcinoma is a protein selected from subgroup 4A, subgroup 4B, and subgroup 4C. In various embodiments the ECM protein is selected from an ECM protein signature characteristic of colon carcinoma metastases. In some embodiments the ECM protein signature characteristic of colon carcinoma metastases is a protein selected from subgroup 5A, subgroup 5B, and subgroup 5C. The ECM protein, in some embodiments, is selected from an ECM protein signature characteristic of metastatic colon carcinoma (primary & secondary). In some embodiments the ECM protein signature characteristic of metastatic colon carcinoma (primary & secondary) is a protein selected from subgroup 6A, subgroup 6B, and subgroup 6C. In other embodiments the ECM protein is selected from an ECM protein signature whose expression is associated with colon cancer or metastatic colon cancer. In some embodiments the ECM protein whose expression is associated with colon cancer or metastatic colon cancer is a protein selected from subgroup 7A, subgroup 7B, and subgroup 7C.

"A method is provided, in aspects of the invention, for determining the presence or absence of one or more ECM proteins characteristic of metastatic carcinoma in a tumor and determining whether the cancerous tissues are metastatic based on the presence or absence of
one or more ECM proteins characteristic of metastatic carcinoma. The method may further comprise treating a subject whose tumor expresses one or more of the ECM proteins characteristic of metastatic carcinoma as identified herein with an anti-cancer agent, optionally any one of the compositions described herein. The presence of one or more of the ECM protein characteristic of metastatic carcinoma in the tumor indicates that the tumor is metastatic, in some embodiments. Two or more ECM protein characteristic of metastatic carcinoma may be detected in the tumor. Optionally, five or more ECM protein characteristic of metastatic carcinoma are detected in the tumor.

"In some embodiments the cancer is breast cancer and the ECM protein is selected from an ECM protein signature characteristic of metastatic mammary carcinoma. In some embodiments the ECM protein signature characteristic of metastatic mammary carcinoma is selected from subgroup 2A, subgroup 2B, and subgroup 2C.

"In other embodiments the tumor is a tumor of the colon. The ECM protein is selected from an ECM protein signature characteristic of metastatic primary colon carcinoma in some embodiments. In some embodiments the ECM protein signature characteristic of metastatic primary colon carcinoma is a protein selected from subgroup 4A, subgroup 4B, and subgroup 4C. In other embodiments the ECM protein is selected from an ECM protein signature characteristic of colon carcinoma metastases. In some embodiments the ECM protein signature characteristic of colon carcinoma metastases is a protein selected from subgroup 5A, subgroup 5B, and subgroup 5C. The ECM protein, in other embodiments, is selected from an ECM protein signature characteristic of metastatic colon carcinoma (primary & secondary). In some embodiments the ECM protein signature characteristic of metastatic colon carcinoma (primary & secondary) is a protein selected from subgroup 6A, subgroup 6B, and subgroup 6C. In other embodiments the ECM protein is selected from an ECM protein signature whose expression is associated with colon cancer or metastatic colon cancer. In some embodiments the ECM protein signature whose expression is associated with colon cancer or metastatic colon cancer is a protein selected from subgroup 7A, subgroup 7B, and subgroup 7C.

"Optionally, the method may involve determining whether an ECM protein characteristic of non-metastatic carcinoma is present in the tumor. In some embodiments the presence of one or more of the ECM proteins characteristic of non-metastatic carcinoma in the tumor indicates that the tumor is not metastatic. In other embodiments the ECM protein is selected from an ECM protein signature characteristic of non-metastatic mammary carcinoma. In some embodiments the ECM protein signature characteristic of non-metastatic mammary carcinoma is a protein selected from subgroup 1A, subgroup 1B, and subgroup 1C.

"Optionally, the tumor may be an isolated tumor sample from a subject.

"In some embodiments a level of expression of the ECM protein characteristic of metastatic carcinoma is measured and is at least twice a baseline level.

"In other embodiments the ECM protein characteristic of metastatic carcinoma is detected by immunohistochemistry.

"The method may be a method of tracking the progression of a tumor to a metastatic state by measuring the presence or absence of one or more ECM protein characteristic of metastatic carcinoma in the tumor over time.

"Alternatively, the method may involve determining whether or not a subject has metastatic cancer comprising, determining the presence or absence of a signature of ECM proteins whose expression is associated with metastatic cancer in an isolated tissue sample from a subject and determining whether the subject has metastatic cancer based on the presence or absence of the signature of ECM proteins, such that when the signature of ECM proteins is present in the isolated tissue sample the subject has metastatic cancer.
"A method for monitoring progression of a tumor to a metastatic state is provided in other aspects of the invention. The method involves measuring the presence or absence of a signature of ECM proteins in tissue samples isolated from the subject at a first time point and a second time point and determining the progression of the tumor to a metastatic state based on changes in the presence or absence of the signature of ECM proteins at the first and second time points. The method may also involve treating a subject having a signature of ECM proteins as identified herein with an anti-cancer agent, optionally any one of the compositions described herein.

"In some embodiments the cancer is colon cancer. The signature of ECM proteins, in some embodiments, includes at least 2, at least 5, at least 10, at least 15, at least 20, at least 25, at least 30 or all of the proteins selected from an ECM protein signature whose expression is associated with colon cancer or metastatic colon cancer. In some embodiments the ECM protein signature whose expression is associated with colon cancer or metastatic colon cancer is a protein selected from subgroup 7A, subgroup 7B, and subgroup 7C. In other embodiments the signature of ECM proteins includes at least 2, at least 5, at least 10, at least 15, at least 20, at least 25, at least 30 or all of the proteins selected from an ECM protein signature characteristic of metastatic colon carcinoma (primary & secondary). In some embodiments the ECM protein signature characteristic of metastatic colon carcinoma (primary & secondary) is a protein selected from subgroup 6A, subgroup 6B, and subgroup 6C. In yet other embodiments the signature of ECM proteins includes at least 2, at least 5, at least 10, at least 15, at least 20, at least 25, at least 30 or all of the proteins selected from an ECM protein signature characteristic of colon carcinoma metastases. In some embodiments the ECM protein signature characteristic of colon carcinoma metastases is a protein selected from subgroup 5A, subgroup 5B, and subgroup 5C. In other embodiments the signature of ECM proteins includes at least 2, at least 5, at least 10, at least 15, at least 20, at least 25, at least 30 or all of the proteins selected from an ECM protein signature characteristic of metastatic primary colon carcinoma. In some embodiments the ECM protein signature characteristic of metastatic primary colon carcinoma is a protein selected from subgroup 4A, subgroup 4B, and subgroup 4C.

"Alternatively, the cancer may be breast cancer. In some embodiments the signature of ECM proteins includes at least 2, at least 5, at least 10, at least 15, at least 20, at least 25, at least 30 or all of the proteins selected from the group consisting of an ECM protein signature characteristic of metastatic mammary carcinoma. In other embodiments the ECM protein signature characteristic of metastatic mammary carcinoma is selected from subgroup 2A, subgroup 2B, and subgroup 2C.

"In yet other embodiments the signature of ECM proteins includes at least 5, at least 15, or at least 30 of the selected proteins.

"The signature of ECM proteins may be a signature characteristic of metastatic carcinoma. In some embodiments when one or more of the ECM proteins characteristic of the signature of metastatic carcinoma is present at a higher level in the isolated tissue samples from the second time point the tumor has progressed to a metastatic state. In other embodiments when the signature of ECM protein characteristic of metastasis is present at a lower level in the isolated tissue samples from the second time point the tumor has regressed to a less metastatic state.

"The method may further comprise the step of determining a level of expression of a signature of primary ECM proteins in the isolated tissue samples and comparing the levels of the signature of primary ECM proteins to the levels of a signature of metastasis ECM proteins.

"In some embodiments the method involves administering a chemotherapeutic agent to the subject before the tissue sample is isolated from the subject at the second time point."
In other embodiments the proteins may be detected using one or more antibodies that specifically bind to the proteins using a mass spectrometry method and/or a chromatographic method or an immunohistochemical technique. The proteins are analyzed using a quantitative ELISA in other embodiments.

A kit is provided in other aspects of the invention. The kit includes a set of binding reagents which interacts specifically with a signature of ECM proteins whose expression is associated with metastatic colon or breast cancer; a set of reagents for performing an immunohistochemistry reaction using the set of binding reagents; and instructions for performing the immunohistochemistry reactions.

In some embodiments the set of binding reagents interacts specifically with at least 2, at least 5, at least 10, at least 15, at least 20, at least 25, at least 30 or all of the proteins selected from an ECM protein signature whose expression is associated with colon cancer or metastatic colon cancer. In some embodiments the ECM protein signature whose expression is associated with colon cancer or metastatic colon cancer is a protein selected from subgroup 7A, subgroup 7B, and subgroup 7C.

In some embodiments the set of binding reagents interacts specifically with at least 2, at least 5, at least 10, at least 15, at least 20, at least 25, at least 30 or all of the proteins selected from an ECM protein signature characteristic of metastatic colon carcinoma (primary & secondary), and instructions include instructions for identifying the presence of ECM proteins characteristic of metastatic colon carcinoma (primary and secondary). In some embodiments the ECM protein signature characteristic of metastatic colon carcinoma (primary & secondary) is a protein selected from subgroup 6A, subgroup 6B, and subgroup 6C.

In some embodiments the set of binding reagents interacts specifically with at least 2, at least 5, at least 10, at least 15, at least 20, at least 25, at least 30 or all of the proteins selected from an ECM protein signature characteristic of colon carcinoma metastases, and wherein the instructions include instructions for identifying the presence of ECM proteins characteristic of colon carcinoma metastases. In some embodiments the ECM protein signature characteristic of colon carcinoma metastases is a protein selected from subgroup 5A, subgroup 5B, and subgroup 5C.

The set of binding reagents interacts specifically with at least 2, at least 5, at least 10, at least 15, at least 20, at least 25, at least 30 or all of the proteins selected from an ECM protein signature characteristic of metastatic primary colon carcinoma, and wherein the instructions include instructions for identifying the presence of ECM protein characteristic of metastatic primary colon carcinoma in other embodiments. In some embodiments the ECM protein signature characteristic of metastatic primary colon carcinoma is a protein selected from subgroup 4A, subgroup 4B, and subgroup 4C.

In yet other embodiments the set of binding reagents interacts specifically with at least 2, at least 5, at least 10, at least 15, at least 20, at least 25, at least 30 or all of the proteins selected from an ECM protein signature characteristic of metastatic mammary carcinoma and wherein the instructions include instructions for identifying the presence of ECM protein characteristic of metastatic mammary carcinoma. In some embodiments the ECM protein signature characteristic of metastatic mammary carcinoma is selected from subgroup 2A, subgroup 2B, and subgroup 2C.

In some embodiments the set of binding reagents interacts specifically with at least 2, at least 5, at least 10, at least 15, at least 20, at least 25, at least 30 or all of the proteins selected from an ECM protein signature characteristic of mammary carcinoma, and wherein the instructions include instructions for identifying the presence of ECM protein characteristic of mammary carcinoma. In some embodiments the ECM protein signature characteristic of
mammary carcinoma is a protein selected from subgroup 3A, subgroup 3B, and subgroup 3C.

"The set of binding reagents interacts specifically with at least five, at least fifteen, or at least thirty of the selected proteins, in some embodiments.

"In other aspects the invention is a method, involving administering to a subject having a tumor an extracellular matrix (ECM) protein inhibitor, wherein the ECM protein inhibitor is an inhibitor of a protein selected from any of the proteins of an ECM protein signature characteristic of non-metastatic mammary carcinoma, an ECM protein signature characteristic of metastatic mammary carcinoma, an ECM protein signature characteristic of mammary carcinoma, an ECM protein signature characteristic of metastatic primary colon carcinoma, an ECM protein signature characteristic of colon carcinoma metastases, an ECM protein signature characteristic of metastatic colon carcinoma (primary & secondary), and an ECM protein signature whose expression is associated with colon cancer or metastatic colon cancer.

"In some embodiments the ECM protein is characteristic of metastatic carcinoma and is selected from an ECM protein signature characteristic of metastatic mammary carcinoma, an ECM protein signature characteristic of metastatic primary colon carcinoma, an ECM protein signature characteristic of colon carcinoma metastases, an ECM protein signature characteristic of metastatic colon carcinoma (primary & secondary), and an ECM protein signature whose expression is associated with colon cancer or metastatic colon cancer.

"This invention is not limited in its application to the details of construction and the arrangement of components set forth in the following description or illustrated in the drawings. The invention is capable of other embodiments and of being practiced or of being carried out in various ways. Also, the phraseology and terminology used herein is for the purpose of description and should not be regarded as limiting. The use of 'including,' 'comprising,' or 'having,' 'containing,' 'involving,' and variations thereof herein, is meant to encompass the items listed thereafter and equivalents thereof as well as additional items."

Keywords for this news article include: Antibodies, Genetics, Oncology, Peptides, Carcinomas, Immunology, Proteomics, Amino Acids, Colon Cancer, Breast Cancer, Blood Proteins, Women's Health, Immunoglobulins, Gastroenterology, Metastatic Cancer, Massachusetts Institute of Technology.

Patents
Patent Issued for Chemical Induction of Lactation in Male Non-Human Mammals (USPTO 9526756)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- From Alexandria, Virginia, NewsRx journalists report that a patent by the inventor Erickson, Jeffrey P. (East Woodstock, CT), filed on May 26, 2015, was published
online on December 27, 2016.

The patent's assignee for patent number 9526756 is Erickson; Jeffrey P. (East Woodstock, CT).

News editors obtained the following quote from the background information supplied by the inventors: "The therapeutic protein market is estimated to surpass $90 billion by 2010. Anonymous. 'Therapeutic Proteins: Research Report' Lead Discovery Ltd. (2005). Therapeutic proteins such as hormones, enzymes, peptides and antibiotics for use in disease therapy have been extracted from human plasma, animal tissues, or produced by recombinant DNA technology. These proteins are used to treat various cancers, heart attacks, stroke, cystic fibrosis, Gaucher's disease, diabetes, anemia and hemophilia. It is important that such products are free of blood-borne pathogens derived from human and animal tissues, thereby making manufacturing costs and capacity concerns that affect the successful commercialization of the therapeutic protein market.

"Presently, an inadequate protein supply and viral safety concerns surrounding plasmid-derived proteins have led to the development of recombinant production of therapeutic proteins. While genetically engineered plants, bacteria and yeast are adequate for producing simple mammalian proteins, they lack the cellular machinery to perform the complex protein glycosylation, carboxylation, assembly of subunits and folding (post-translational modification (PTM)), for biological activity.

"Consequently, it is a long felt need in the art to develop technology such that large amounts of transgenic proteins may be economically collected and processed from non-human transgenic mammals."

As a supplement to the background information on this patent, NewsRx correspondents also obtained the inventor's summary information for this patent: "The present invention is related to the field of transgenic animals. Specifically, the invention is related to the expression of transgenic proteins in the milk of mammals. Lactation inducers have been utilized to optimize the production and collection of milk from transgenic mammals. It is contemplated that lactation may be induced in either male or female swine using a combination of a non-17.beta. estradiol, domperidone and oxytocin.

"In one embodiment, the present invention contemplates a method, comprising: a) providing; i) a first composition comprising an estrogen compound, wherein said first composition is a pharmaceutically acceptable formulation; ii) a second composition comprising a dopaminergic antagonist, wherein said second composition is a pharmaceutically acceptable formulation; iii) a third composition comprising oxytocin, wherein said third composition is a pharmaceutically acceptable formulation; iii) a non-pregnant mammal; b) administering a single dose of said first composition to said mammal; c) administering a single dose of said second composition to said mammal; and d) administering a single dose said third composition to said mammal. In one embodiment, the estrogen compound is long acting. In one embodiment, the third composition is administered on a daily basis after administering the second composition.

"In one embodiment, the present invention contemplates a method for inducing lactation in non-pregnant animals by administering a combination of estradiol, domperidone, and oxytocin. In one embodiment, the estradiol is not a 17.beta.-estradiol. In one embodiment, the combination of estradiol, domperidone, and oxytocin is administered to the mammal sequentially. In one embodiment, the combination of estradiol, domperidone, and oxytocin is administered to the mammal simultaneously. In one embodiment, the sequential administration comprises a separation of at least one hour. In one embodiment, the sequential administration comprises a separation of at least six hours. In one embodiment, the sequential administration comprises a separation of at least twelve hours. In one embodiment, the sequential
administration comprises a separation of at least one day. In one embodiment, the sequential administration comprises a separation of at least three days. In one embodiment, the sequential administration comprises a separation of at least seven days. In one embodiment, the sequential administration comprises a separation of at least fourteen days. In one embodiment, the method further comprises an administration of a pharmaceutically acceptable formulation comprising altrenogest. In one embodiment, the estradiol is long acting.

“In one embodiment, the present invention contemplates a method, comprising: a) providing; i) a first composition comprising a non-17.beta. estradiol, wherein said first composition is a pharmaceutically acceptable formulation; ii) a second composition comprising domperidone, wherein said second composition is a pharmaceutically acceptable formulation; iii) a third composition comprising oxytocin, wherein said third composition is a pharmaceutically acceptable formulation; iii) a non-pregnant mammal; b) administering a single dose of said first composition to said mammal; c) administering a single dose of said second composition to said mammal; d) administering a single dose said third composition to said mammal. In one embodiment, the method further comprises step (e) collecting a commercially viable volume of milk from said mammal. In one embodiment, the second composition is administered fourteen days after said first composition. In one embodiment, the third composition is administered twenty-four hours after said second composition. In one embodiment, the third composition is administered on a daily basis after said second composition. In one embodiment, the first composition is administered orally. In one embodiment, the second composition is administered orally. In one embodiment, the third composition is administered parenterally. In one embodiment, the parenteral administration comprises an intramuscular injection. In one embodiment, the oral administration comprises a gel. In one embodiment, the milk is collected on the same day as said oxytocin administration. In one embodiment, the non-pregnant mammal is a female. In one embodiment, the non-pregnant mammal is a male. In one embodiment, the female mammal is nulliparous. In one embodiment, the female mammal has not been pregnant for at least six months. In one embodiment, the female mammal has not been pregnant for at least twelve months. In one embodiment, the female mammal has delivered at least one litter. In one embodiment, the female mammal is a virgin. In one embodiment, the female mammal is prepubertal. In one embodiment, the non-17.beta. estradiol is long acting.”

Siemens PLC

Patent Issued for Combined MRI and Radiation Therapy System (USPTO 9526918)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A patent by the inventor Kruip, Marcel (Oxfordshire, GB), filed on November 12, 2013, was published online on December 27, 2016, according to news reporting originating from Alexandria, Virginia, by NewsRx correspondents.

Patent number 9526918 is assigned to Siemens PLC (Camberley, GB).

The following quote was obtained by the news editors from the background information supplied by the inventors:

"Field of the Invention"

"The present invention relates to combined MRI and radiation therapy equipment.

"Description of the Prior Art"

"Certain examples of combined MRI and radiation therapy equipment are known, but suffer from certain drawbacks. The present invention addresses at least some of those drawbacks.

"Radiation therapy typically uses gamma radiation, or similar, to target cancerous tissues in a patient. Such radiation may be generated either using an electron beam generated by an accelerator and aimed at a suitable target, or a radiation source containing a suitable radioactive isotope, such as cobalt-60.

"The use of a cobalt-60 source involves difficulties in storage, and prevention of over-exposure by operators. Screening of such sources can only be achieved by significant amounts of dense material such as lead or tungsten. Such sources are simple and are not affected by magnetic fields such as would be encountered in a combined MRI and radiation therapy system. The radiation produced is however of relatively low energy, and cannot be intensity-modulated.

"Radiation generation by electron beam acceleration onto a suitable target has the advantages of being able to produce higher-energy photons, and may be intensity modulated.

"The accelerators required to produce an electron beam, typically linear accelerators, are very sensitive to transverse magnetic fields, which makes their incorporation into MRI equipment difficult. The magnetic field deflects the path of the electron beam within the accelerators, destroying the efficacy of such radiation sources.

"An example arrangement which allows a linear electron accelerator (LINAC) to be built into an MRI system and used for combined MRI and radiation therapy is known from WO2003008986 and uses a radially-aligned LINAC. The LINAC and its associated target are arranged to project a radiation beam through an aperture or transparent window in a cryostat, between coils of a superconducting MRI magnet. The radially-aligned LINAC is arranged on the mid-plane of the magnet, and requires a lot of space around the magnet, making it impractical for many installations. The magnetic field of the main magnet is transverse to the LINAC, and interferes with the electron beam path. Only relatively low main magnet field strength (flux density) can be tolerated.

"A more compact arrangement of combined MRI and radiation therapy equipment is described in US Patent publication US2011/0213239A1, International Patent publication WO2012049466 and UK Patent GB2484529. In this arrangement, the linear accelerator (LINAC) is arranged parallel to the axis of the magnet and is situated between gradient coils and the main magnet field coils of an MRI system. Beam steering arrangements are provided to
deflect the generated electron beam from an axial path, parallel to the axis of the magnet, to a radial path, perpendicular to the axis, and then onto a suitable target. The LINAC and target are accordingly immersed in a relatively strong magnetic field.

"FIG. 1 corresponds to FIG. 1 of WO2012049466, US2011/0213239A1 and GB2484529. It shows a schematic representation of a conventional combined radiation therapy and magnetic resonance unit 1 with a magnetic resonance imaging part 3 and a radiation therapy part 5. The magnetic resonance imaging part 3 includes a main magnet 10, a gradient coil system having two (in this case symmetrical) partial gradient coils 21A, 21B, radio-frequency coils 14, for example two parts of a body coil 14A, 14B, and a patient bed 6. All these components of the magnetic resonance imaging part 3 are connected to a control unit 31 and an operating and display console 32.

"Both the main magnet 10 and the partial gradient coils 21A, 21B are essentially shaped like a hollow cylinder and arranged coaxially around the horizontal axis 15. The inner shell of the main magnet 10 limits in radial direction (perpendicular to the axis 15) a cylinder-shaped interior 7, in which the radiation therapy part 5, the gradient system, high-frequency coils 14 and the patient bed 6 are arranged. More precisely the radiation therapy part 5 is located in the interior 7 between a radially outer side of the gradient coil system 21A and 21B and a radially inwardly facing surface of a housing of the main magnet 10.

"In addition to the magnet coils, the main magnet 10 comprises further structural elements, such as supports, housing etc., and generates a homogenous main magnetic field necessary for magnetic resonance imaging. In the example shown, the direction of the main magnetic field is parallel to the horizontal axis 15. High-frequency coils 14 are used to excite nuclear spins in the patient. The signals emitted by the excited nuclear spins are received by the high-frequency coils 14.

"The axially spaced-apart partial gradient coils 21A, 21B in each case include gradient coils 20, which are in each case completely enclosed by a shield 27. The gradient coil 20 has supports and individual gradient coils that generate magnetic gradient fields for selective layer excitation and for location-coding of the magnetic resonance signals in three spatial directions.

"The radiation therapy part 5 is arranged on a gantry 8 and comprises a linear electron accelerator (LINAC) 9, a beam deflection arrangement 17, a target anode 19, a homogenizing body 22 and a collimator 23. The gantry 8 can feature a through-hole (broken lines), by which access to the magnetic resonance imaging 3 part is possible, through the gantry.

"The LINAC 9 has an electron source 11, for example a tungsten cathode, which generates an electron beam 13, which is accelerated parallel to the axis 15 of the main magnet 10. If the LINAC 9 generates pulsed electron beams 13, it can be built more compactly than one designed to provide a continuous electron beam. The LINAC 9 for example may generate electron beam pulses with a length of 5 .mu.s every 5 ms.

"The electrons of the electron beam 13 are accelerated by electric alternating fields in cylinder-shaped hollow conductors of the LINAC 9. The electrons of the electron beam 13 are accelerated to energies up to a magnitude of several MeV. The LINAC 9 is connected to an accelerator control unit 12 to control the alternating fields and the electron source 11.

"The electron beam 13 leaves the LINAC 9 at the end opposite the electron source and is deflected by the beam deflection arrangement 17 through 90.degree. radially inward towards axis 15. For this purpose the beam deflection arrangement 17 may have a magnet configured as an electromagnet made of non-ferromagnetic materials to prevent undesired interaction with the surrounding magnetic fields.

"To be able to deflect the pulsed electron beam 13 in a small space, the beam
deflection arrangement 17 must generate strong magnetic fields. To reduce the power loss, the magnetic field of the beam deflection arrangement 17 is a pulsed electro-magnetic field which is synchronized with the pulsed electron beam 13. For this purpose the beam deflection arrangement 17 is connected to a beam deflection control unit 18 which is also connected to the accelerator control unit 12.

"The deflected electron beam 13 hits the target anode 19 and generates a radiation beam that emerges from the target anode in the beam elongation along a beam path. The radiation beam is homogenized by the homogenizing body 22.

"The collimator 23 is arranged in an annular slot between the distanced partial gradient coils 21A, 21B in the beam path after the target anode 19. The proximity to the irradiation target thus achieved improves the radiation luminance and the effectiveness of the collimator 23.

"The collimator 23 enables the direction of the radiation beam and the cross-section of the radiation beam to be influenced. For this purpose the collimator 23 preferably incorporates moveable adjusters 24, which permit the radiation beam to pass only in a certain direction, e.g. only parallel to the radial direction 26 or up to an angle \( \alpha \) away from the beam axis 26, and with a certain cross-section. It is also possible to set the adjusters 24 of the collimator 23 in such a way that no radiation beams can pass parallel to the radial beam axis direction 26 and only angled radiation beams at certain angles from the radial direction 26 can pass through. To control the adjusters 24, the collimator 23 is connected to a collimator control unit 25. Such collimators are adequately known. By way of example, reference can be made to multi-leaf collimators. They make it possible to perform intensity modulated radiation therapy (IMRT), in which the size, shape and intensity of the radiation beam can be optimally adapted to the irradiation target. In particular IMRT also enables the irradiation center to be positioned outside the rotational axis of the radiation therapy device.

"The radiation beam penetrates the examination subject, in this case the patient P, and the radiation beam path runs through a diagnosis (imaging) volume D of the magnetic resonance imaging part 3. To minimize the local dose of radiation outside the irradiation target volume, the radiation therapy part rotates around the axis 15 of the main magnetic field. As a result, the full dose is applied only in the irradiation center B. The collimator 23 constantly adapts the cross-section of the radiation beam to the actual outline of the irradiation target even during rotation. The gantry 8 is configured for rotation of the radiation therapy part. A gantry control unit 29 controls the movement of the radiation therapy part 5. As an example the radiation therapy part 5 is shown as radiation therapy part 5' after rotation through 180 degree.

"The gantry control unit 29, the collimator control unit 25, the beam deflection control unit 18, the accelerator control unit 12 and the control unit 31 are connected to each other so that the diagnosis data collected by the magnetic resonance imaging part, for example the three-dimensional shape of the irradiation target, the rotational position of the radiation therapy part, as well as the collimator settings with regard to cross-section and direction of the radiation beam and the generation of pulsed beams described above can be coordinated with each other.

"The patient bed 6 is preferably moveable in three spatial directions so that the target area of the irradiation can be positioned precisely in the irradiation center B. For this purpose the control unit 31 is expediently configured for controlling a movement of the patient bed.

"This known arrangement, however, suffers from certain disadvantages. By locating the LINAC 9 and the target 19 within the main magnet 10, the coils of the main magnet must be of relatively large diameter, and the LINAC and target must be located close to the main magnet coils, in order to keep the overall size of the system to an acceptable diameter. Operation of this
arrangement has been demonstrated experimentally, but only where the magnetic field experienced by the LINAC 9 is of sufficient homogeneity. This is difficult to achieve when the LINAC is positioned close to the main magnet coils, as the electron beam quality may be degraded by variations in the magnetic field experienced by the electron beam due to variations in magnetic field orientation and strength. The magnetic resonance imaging part is designed to generate a homogeneous magnetic field in a central imaging region, and the magnetic field in the volume occupied by the LINAC 9 is rather less homogeneous. The magnetic field will be strong within the bore of the main magnet 10, but the magnetic field lines in the region will not be truly parallel, particularly near the end of the magnet, and some deflection and dispersion of the beam will result.

"The arrangement of FIG. 1 does not allow much space for radiation beam shaping devices such as multi-leaf collimator (MLC) conventionally and advantageously provided in radiation therapy equipment."

In addition to the background information obtained for this patent, NewsRx journalists also obtained the inventor's summary information for this patent: "The present invention accordingly addresses at least some of these disadvantages and provides combined MRI and radiation therapy equipment as described below.

"According to the present invention, the LINAC required for generating an electron beam, which is in turn required for generating a radiation beam, is located radially outside of the main magnet, and accordingly allows the diameter of the main magnet coils to be reduced.

"The invention is applicable to actively-shielded solenoidal magnets, wherein shield coils of diameter greater than the main coils, but arranged coaxially with the main magnet coils, carry a current in the opposite direction as compared to a current carries by the main magnet coils. As is well known to those skilled in the art, such shield coils reduce the magnitude of a stray field around the MRI system. Preferably, the LINAC is arranged parallel to the axis of the main magnet, radially positioned between the radially outer surface of the main magnet coils and the radially inner surface of the shield coils. In this way, the combined MRI and radiation therapy equipment of the present invention has an outer diameter similar to that of a comparable MRI system, allowing installation in locations which would be impractical for a conventional combined MRI and radiation therapy system."

Our reports deliver fact-based news of research and discoveries from around the world. Copyright 2017, NewsRx LLC
The patent's inventor is Ross, Russell Frederick (Atlanta, GA).

This patent was filed on April 27, 2011 and was published online on December 27, 2016.

From the background information supplied by the inventors, news correspondents obtained the following quote: "Primary drug delivery methods include oral delivery and injections, but these methods present difficulties. For instance, injections are painful and both methods tend to provide bursts of agents rather than a preferred steady-state delivery. Additionally, the successful long term use of both oral delivery and injected delivery requires the patient to consistently meet the time requirements for the delivery method.

"Transdermal delivery materials have been developed in an attempt to provide a painless route for delivery of active agents over a sustained period with little or no interruption of the patient's daily routine. Unfortunately, natural dermal characteristics such as the overlapping corneocytes of the stratum corneum, the tight junction of the stratum granulosum, and Langerhans cells of the stratum spinosum that may institute an immune response and/or a foreign body response all present barriers to successful transdermal delivery of an active agent.

"Devices including microneedles that may facilitate transdermal delivery of active agents have improved transdermal delivery. A microneedle transdermal device includes an array of needles that may penetrate at least the stratum corneum of the skin and reach an underlying layer of the skin. In some devices, the microneedles are designed so as to penetrate to a depth that does not stimulate the nerve endings and institute a pain response. Examples of microneedle devices have been described in U.S. Pat. No. 6,334,856 to Allen, et al. and U.S. Pat. No. 7,226,439 to Prausnitz, et al., both of which are incorporated herein by reference.

"Unfortunately, even with the inclusion of microneedles on a transdermal device, transdermal devices are presently limited to delivery of low molecular weight agents that have a moderate lipophilicity and no charge. Even upon successful crossing of the natural dermal boundary, problems still exist with regard to maintaining the activity level of delivered agents and avoidance of foreign body and immune response.

"The nanotopography of a surface adjacent to a cell has been found to affect adhesive characteristics between the two as well as to effect cell behavior including morphology, motility, cytoskeleton architecture, proliferation, and differentiation (see, e.g., Hart, et al., European Cells and Materials, Vol. 10, Suppl. 2, 2005; Lim, et al., J R Soc Interface, Mar. 22, 2005, 2(2), 97-108; Yim, et al., Biomaterials, September, 2005, 26(26), 5405-5413). As an extension of this initial research, nanotopography of supporting substrates has been examined for use in tissue engineering (see, e.g., U.S. Patent Application Publication Nos. 2008/0026464 to Borenstein, et al. and 2008/0311172 to Schapira, et al.).

"What are needed in the art are improved drug delivery devices. For instance, devices that provide efficient delivery of active agents while decreasing potential immune and foreign body response to both the delivery device and the delivered agents would be beneficial."

Supplementing the background information on this patent, NewsRx reporters also obtained the inventor's summary information for this patent: "According to one embodiment, disclosed is a composite microneedle array. An array may include a microneedle assembly that includes a support having a first surface and a second surface, wherein a plurality of microneedles extend outwardly from the first surface. An array may also include a film overlaying the microneedles of the microneedle assembly that at least partially conforms to the shape of the microneedles. The film may have a first surface and a second surface. The first surface of the film may be adhered to the microneedle assembly, and the second surface of the film may include thereon a plurality of nanostructures, the nanostructures being arranged in a
predetermined pattern.

"Also disclosed is a method for forming a composite microneedle array. A method may include laying a film over a microneedle assembly and engaging the film with the microneedle assembly such that the film at least partially conforms to the microneedles of the array and adheres to the microneedle assembly."

For the URL and additional information on this patent, see: Ross, Russell Frederick. Composite Microneedle Array Including Nanostructures Thereon. U.S. Patent Number 9526883, filed April 27, 2011, and published online on December 27, 2016. THE JOHNS HOPKINS UNIVERSITY

Patent Issued for Compounds for Treating Peripheral; Neuropathies and Other Neurodegenerative; Disorders (USPTO 9527817)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- THE JOHNS HOPKINS UNIVERSITY (Baltimore, MD) has been issued patent number 9527817, according to news reporting originating out of Alexandria, Virginia, by NewsRx editors.

The patent's inventors are Hoke, Ahmet (Towson, MD); Chen, Weiran (Columbia, MD); Zhu, Jing (Ellicott City, MD).

This patent was filed on June 21, 2012 and was published online on December 27, 2016.

From the background information supplied by the inventors, news correspondents obtained the following quote: "Neurodegenerative disorders affect many people worldwide. These disorders include peripheral neuropathies, which are a group of neurodegenerative disorders affecting the peripheral nerves, such as peripheral neuropathy caused by chemotherapy or diabetes; disorders of the central nervous system, such as Alzheimer's disease and Parkinson's disease; and motor neuron diseases, such as amyotrophic lateral sclerosis (ALS). Currently, no effective therapy for preventing nerve degeneration exists, except in cases of autoimmune peripheral neuropathies.

"Heat shock proteins are a class of functionally related proteins involved in the folding and unfolding of other proteins. They play an important role in the cell under normal conditions and also are a primary part of the heat shock response. They make up approximately 1% to 2% of total protein in unstressed cells. This percentage increases to 4% to 6% of total protein in cells that are stressed, such as during elevated temperatures, inflammation, or infection.

"Heat shock proteins have several important functions in a cell under normal conditions. One function is to act as intracellular chaperones for other proteins. By helping to
stabilize partially unfolded proteins, heat shock proteins aid in transporting proteins across membranes within a cell. They also play an important role in other protein-protein interactions, such as protein folding, assisting in the establishment of proper protein conformation, preventing unwanted protein aggregation, and carrying old proteins destined for degradation to a proteasome in the cell.

"Heat shock proteins, however, also can assist in promoting diseases or disorders. For example, heat shock proteins can aid in the correct functioning of tumor promoting proteins, such as oncoproteins, and they have been found to be overexpressed in a range of cancers. They also may contribute to tumor cell survival by stabilizing aberrant signaling proteins and by interfering with apoptosis."

Supplementing the background information on this patent, NewsRx reporters also obtained the inventors' summary information for this patent: "In some aspects, the presently disclosed subject matter provides a method for treating, inhibiting, delaying, or preventing a neurodegenerative disorder in a subject, the method comprising administering to the subject a therapeutically effective amount of a compound of Formula (I) or Formula (II):

###STR00001###

wherein: R.sub.1 is selected from the group consisting of H, substituted or unsubstituted alkyl, and --C(.dbd.O)--R.sub.6, wherein R.sub.6 is substituted or unsubstituted alkyl; R.sub.2, R.sub.3, and R.sub.4 are each independently substituted or unsubstituted alkyl; and R.sub.5 is selected from the group consisting of H, substituted or unsubstituted alkyl, and --C(.dbd.O)--R.sub.6; or a pharmaceutically acceptable salt thereof.

In particular aspects, the compound of Formula (I) or Formula (II) is selected from the group consisting of:

###STR00002###

"In yet more particular aspects, the compound of Formula (I) is:

###STR00003###

In particular embodiments, the peripheral neuropathy is selected from the group consisting of a chemotherapy-induced peripheral neuropathy, a diabetes-induced peripheral neuropathy, an HIV-associated peripheral neuropathy, an idiopathic peripheral neuropathy, an alcohol-induced peripheral neuropathy, and a drug-induced peripheral neuropathy.

In other aspects, the neurodegenerative disorder is of the central nervous system. In some embodiments, the neurodegenerative disorder is selected from the group consisting of Alzheimer’s disease, and Parkinson’s disease. In yet other aspects, the neurodegenerative disorder comprises a motor neuron disease. In some embodiments, the motor neuron disease is amyotrophic lateral sclerosis (ALS).

"In another aspect, the presently disclosed subject matter provides a method for modulating the overall activity of heat shock protein 90 (hsp90) without modulating the ATPase activity of hsp90 in a cell, the method comprising contacting the cell with a compound of Formula (I) or Formula (II), as defined hereinabove, in an amount sufficient to modulate the overall activity of hsp90 but not modulate the ATPase activity of hsp90.

In another aspect, the presently disclosed subject matter provides a method for screening for a neuroprotective compound that modulates the overall activity of hsp90, but does not modulate the ATPase activity of hsp90, the method comprising: contacting a cell having hsp90 overall activity with a candidate neuroprotective compound; contacting a cell that is inhibited for hsp90 overall activity with the candidate neuroprotective compound; adding a stress that can result in a neurodegenerative disorder to each cell; determining if the compound provides neuroprotection of the cell having hsp90 overall activity and does not provide neuroprotection of the cell which is inhibited for hsp90 overall activity; and determining the
ATPase activity of hsp90 in the cell having hsp90 overall activity.

"In yet another aspect, the presently disclosed subject matter provides a compound of the formula:

"#STR00004## or a pharmaceutically acceptable salt thereof.

"Certain aspects of the presently disclosed subject matter having been stated hereinabove, which are addressed in whole or in part by the presently disclosed subject matter, other aspects will become evident as the description proceeds when taken in connection with the accompanying Examples and Figures as best described herein below."

Keywords for this news article include: ATPase, Dementia, Peptides, Neurology, Amino Acids, Tauopathies, Efferent Neurons, Alzheimer Disease, Movement Disorders, Heat-Shock Proteins, Parkinson's Disease, Risk and Prevention, Molecular Chaperones, Motor Neuron Disease, Enzymes and Coenzymes, Peripheral Neuropathy, Parkinsonian Disorders, TDP-43 Proteinopathies.

Pharmaceutical Companies

Patent Issued for Controlled Release Hydrocodone Formulations (USPTO 9526724)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Purdue Pharma L.P. (Stamford, CT) has been issued patent number 9526724, according to news reporting originating out of Alexandria, Virginia, by NewsRx editors.

The patent's inventors are Oshlack, Benjamin (Boca Raton, FL); Huang, Hua-Pin (Englewood Cliffs, NJ); Masselink, John K. (Old Tappan, NJ); Tonelli, Alfred (Congers, NY).

This patent was filed on February 9, 2016 and was published online on December 27, 2016.

From the background information supplied by the inventors, news correspondents obtained the following quote: "Once-a-day sustained release opioid formulations are disclosed in U.S. Pat. Nos. 5,478,577; 5,672,360; 5,958,459; 6,103,261; 6,143,332; 5,965,161; 5,958,452 and 5,968,551. All documents cited herein, including the foregoing, are incorporated by reference in their entireties for all purposes."

Supplementing the background information on this patent, NewsRx reporters also obtained the inventors' summary information for this patent: "It is an object of the present invention to substantially improve the efficiency and quality of pain management in human patients experiencing moderate pain.

"It is an object of certain embodiments of the present invention to provide bioavailable hydrocodone formulations suitable for once daily administration which substantially improve the efficiency and quality of pain management."
"It is an object of certain embodiments of the present invention to provide bioavailable controlled-release hydrocodone formulations suitable for once daily administration which provide a substantially increased duration of effect as compared to immediate release hydrocodone formulations.

"It is an object of certain embodiments of the invention to provide orally administrable controlled release opioid formulations suitable for once-a-day administration which provide an early onset of therapeutic effect and which, after rising to a maximum concentration during the dosage interval, provide a relatively flat serum plasma profile, meaning that the plasma level of the opioid provides a C.sub.24/C.sub.max ratio of about 0.55 to about 1.0, and which provides effective pain relief to the patient.

"The above objects and others are attained by virtue of the present invention, which in certain embodiments, provides a solid oral controlled-release dosage form comprising an analgesically effective amount of hydrocodone or a pharmaceutically acceptable salt thereof and a sufficient amount of a controlled release material to render the dosage form suitable for once-a-day administration, the dosage form after administration to a human patient or a population of patients providing a time to peak plasma concentration of hydrocodone in-vivo preferably from about 4 to about 14 hours (T.sub.max), and providing a C.sub.24/C.sub.max ratio of 0.55 to 1.0.

"In certain embodiments of the invention, the dosage form provides a time to maximum plasma concentration (T.sub.max) of hydrocodone in-vivo at about 6 to about 12 hours, at about 8 to about 10 hours, at about 4 to about 10 hours or at about 8 to about 14 hours after administration of the dosage form.

"In certain embodiments of the invention, the dosage form provides a C.sub.24/C.sub.max ratio of 0.55 to 1.0, of 0.55 to about 0.85, of 0.55 to 0.75 or of 0.60 to about 0.70.

"In certain preferred embodiments, the controlled release dosage form provides an in-vitro release when measured by the USP Basket Method at 100 rpm in 700 ml Simulated Gastric Fluid (SGF) at 37.degree. C. for 1 hour and thereafter switching to 900 ml with Phosphate Buffer to a pH of 7.5 at 37.degree. C., of at least 20% by weight hydrocodone or salt thereof released at 4 hrs, from about 20% to about 65% by weight hydrocodone or salt thereof released at 8 hrs, from about 45% to about 85% by weight hydrocodone or salt thereof released at 12 hrs, and at least 80% by weight hydrocodone or salt thereof released at 24 hours. Although the in-vitro release rate may be either pH-independent or pH-dependent as desired, in preferred embodiments of the invention the release of hydrocodone is pH-independent.

"In certain preferred embodiments, the controlled release dosage form provides an in-vitro release of the hydrocodone when measured by the USP Basket method at 100 rpm in 700 ml aqueous buffer at a pH of 1.2 at 37.degree. C. of from 10% to about 45% by weight hydrocodone or salt thereof released at 1 hour.

"In certain embodiments of the invention, the dosage form provides an in-vitro release rate, of hydrocodone or a pharmaceutically acceptable salt thereof, when measured by the USP Basket Method at 100 rpm in 900 ml aqueous buffer at a pH of between 1.6 and 7.2 at 37.degree. C. of from 0% to about 35% at 1 hour, from about 10% to about 70% at 4 hours, from about 20% to about 75% at 8 hours, from about 30% to about 80% at 12 hours, from about 40% to about 90% at 18 hours, and greater than about 60% at 24 hours; the in-vitro release rate being substantially independent of pH in that a difference, at any given time, between an amount of opioid released at one pH and an amount released at any other pH, when measured in-vitro using the USP Paddle Method of U.S. Pharmacopeia XXII (1990) at 100 rpm in 900 ml aqueous buffer, is no greater than 10%.

"In certain preferred embodiments the sustained release oral dosage form of the
The present invention provides hydrocodone plasma levels which are effective for 24 hourly dosing, characterized by a W.sub.50 for the hydrocodone of between 4 and 22 hours. In certain embodiments, the W.sub.50 is at least 4 hours, preferably at least 12 hours, and more preferably at least 18 hours.

"In certain embodiments the sustained release oral dosage form of the present invention comprises a matrix which includes a sustained release material and hydrocodone or a pharmaceutically acceptable salt thereof. In certain embodiments, the matrix is compressed into a tablet and may be optionally overcoated with a coating that in addition to the sustained release material of the matrix may control the release of the hydrocodone or pharmaceutically acceptable salt thereof from the formulation, such that blood levels of active ingredient are maintained within the therapeutic range over an extended period of time. In certain alternate embodiments, the matrix is encapsulated.

"In certain embodiments, the sustained release oral dosage form of the present invention comprises a plurality of pharmaceutically acceptable sustained release matrices comprising hydrocodone or a pharmaceutically acceptable salt thereof, the dosage form maintaining the blood plasma levels of hydrocodone within the therapeutic range over an extended period of time when administered to patients.

"In certain embodiments the sustained release oral dosage form of the present invention is an osmotic dosage form which comprises a single layer or bilayer core comprising hydrocodone or a pharmaceutically acceptable salt thereof; an expandable polymer; a semipermeable membrane surrounding the core; and a passageway disposed in the semipermeable membrane for sustained release of the hydrocodone or pharmaceutically acceptable salt thereof, such that blood levels of active ingredient are maintained within the therapeutic range over an extended period of time when administered to patients.

"In certain preferred embodiments of the invention, there is provided a once-a-day oral controlled release dosage form of hydrocodone which provides a C.sub.max of hydrocodone which less than about 60%, less than about 50% or less than about 40% of the C.sub.max of an equivalent dose of an immediate release hydrocodone reference formulation (e.g. Lortab.RTM.), and which provides effective analgesia during the 24 hour dosage interval.

"In certain preferred embodiments of the invention, there is provided a once-a-day oral controlled release hydrocodone dosage form which provides a rate of absorption during the time period from T.sub.max to about 24 hours after oral administration of the dosage form which is from about 45% to about 85% of the rate of elimination during the same time period.

"In certain preferred embodiments the dosage form of the present invention provides a therapeutic effect for at least about 24 hours after administration of the dosage form.

"In certain embodiments, any one or all of the above in-vivo parameters are achieved after a first administration of the dosage form to a human patient or a population of human patients.

"In certain alternative embodiments, any one or all of the above in-vivo parameters are achieved after steady state administration of the dosage form to a human patient or a population of human patients.

"Hydrocodone' is defined for purposes of the invention as including hydrocodone free base, as well as pharmaceutically acceptable salts and complexes of hydrocodone.

"The term 'USP Paddle or Basket Method' is the Paddle and Basket Method described, e.g., in U.S. Pharmacopoeia XXII (1990), herein incorporated by reference.

"The term 'pH-dependent' for purposes of the present invention is defined as having characteristics (e.g., dissolution) which vary according to environmental pH.
"The term 'pH-independent' for purposes of the present invention is defined as having characteristics (e.g., dissolution) which are substantially unaffected by pH.

"The term 'bioavailability' is defined for purposes of the present invention as the extent to which the drug (e.g., hydrocodone) is absorbed from the unit dosage forms.

"The term 'controlled-release' is defined for purposes of the present invention as the release of the drug (e.g., hydrocodone) at such a rate that blood (e.g., plasma) concentrations are maintained within the therapeutic range but below toxic concentrations over a period of time of about 12 hours or longer.

"The term 'C.sub.max' denotes the maximum plasma concentration obtained during the dosing interval.

"The term 'C.sub.24' as it is used herein is the plasma concentration of the drug at 24 hours after administration.

"The term 'T.sub.max' denotes the time to maximum plasma concentration (Cmax).

"The term 'W.sub.50' for purposes of the present invention is the duration over which the plasma concentrations are equal to or greater than 50% of the peak concentration.

"The term 'C.sub.24/C.sub.max ratio' is defined for purposes of the present invention as the ratio of the plasma concentration of the drug at 24 hours after administration to the highest plasma concentration of the drug attained within the dosing interval.

"The term 'semipermeable wall' for purposes of the present invention means that the wall is permeable to the passage of an exterior fluid, such as aqueous or biological fluid, in the environment of use, including the gastrointestinal tract, but impermeable to drug.

"The term 'minimum effective analgesic concentration' or 'MEAC' with respect to concentrations of opioids such as hydrocodone is very difficult to quantify. However, there is generally a minimally effective analgesic concentration of plasma hydrocodone below which no analgesia is provided. While there is an indirect relationship between, e.g., plasma hydrocodone levels and analgesia, higher and prolonged plasma levels are generally associated with superior pain relief. There is a lag time or hysteresis, between the time of peak plasma hydrocodone-levels and the time of peak drug effects. This holds true for the treatment of pain with opioid analgesics in general.

"For purposes of the invention, unless further specified, the term 'a patient' means that the discussion (or claim) is directed to the pharmacokinetic parameters of an individual patient or subject.

"The term 'population of patients' means that the discussion (or claim) is directed to the mean pharmacokinetic parameters of at least two patients or subjects.

"The term 'immediate release hydrocodone reference formulation' for purposes of the present invention, is an equivalent amount of the hydrocodone portion of Lortab.RTM., commercially available from UCB Pharma, Inc, or a pharmaceutical product that provides an immediate release of hydrocodone or a salt thereof.

"For purposes of the invention, the controlled release formulations disclosed herein and the immediate release control formulations are dose proportional. In such formulations, the pharmacokinetic parameters (e.g., AUC and C.sub.max) increase linearly from one dosage strength to another. Therefore the pharmacokinetic parameters of a particular dose can be inferred from the parameters of a different dose of the same formulation.

"The term 'first administration' means a single dose of the present invention at the initiation of therapy to an individual patient or a patient population.

"The term 'steady state' means that the amount of the drug reaching the system is approximately the same as the amount of the drug leaving the system. Thus, at 'steady-state', the
patient's body eliminates the drug at approximately the same rate that the drug becomes available to the patient's system through absorption into the blood stream.

"The controlled-release oral solid dosage forms of the present invention may be opioid-sparing. It is possible that the controlled-release oral solid dosage forms of the present invention may be dosed at a substantially lower daily dosage in comparison to conventional immediate-release products, with no difference in analgesic efficacy. At comparable daily dosages, greater efficacy may result with the use of the controlled-release oral solid dosage forms of the present invention in comparison to conventional immediate-release products."

Patent Issued for Detachable End Effector and Loader (USPTO 9526516)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- According to news reporting originating from Alexandria, Virginia, by NewsRx journalists, a patent by the inventors Parihar, Shailendra K. (Mason, OH); Haberstich, Wells D. (Loveland, OH), filed on August 31, 2015, was published online on December 27, 2016.

The assignee for this patent, patent number 9526516, is Ethicon Endo-Surgery, LLC (Guaynabo, PR).

Reporters obtained the following quote from the background information supplied by the inventors: "The present invention relates in general to surgical devices and procedures, and more particularly to minimally invasive surgery.

"Surgical procedures are often used to treat and cure a wide range of diseases, conditions, and injuries. Surgery often requires access to internal tissue through open surgical procedures or endoscopic surgical procedures. The term 'endoscopic' refers to all types of minimally invasive surgical procedures including laparoscopic, arthroscopic, natural orifice intraluminal, and natural orifice transluminal procedures. Endoscopic surgery has numerous advantages compared to traditional open surgical procedures, including reduced trauma, faster recovery, reduced risk of infection, and reduced scarring. Endoscopic surgery is often performed with an insufflatory fluid present within the body cavity, such as carbon dioxide or saline, to provide adequate space to perform the intended surgical procedures. The insufflated cavity is generally under pressure and is sometimes referred to as being in a state of pneumoperitoneum. Surgical access devices are often used to facilitate surgical manipulation of internal tissue while maintaining pneumoperitoneum. For example, trocars are often used to provide a port through which endoscopic surgical instruments are passed. Trocars generally
have an instrument seal, which prevents the insufflatory fluid from escaping while an instrument is positioned in the trocar.

"While a variety of different minimally invasive surgical devices are known, no one has previously made or used the surgical devices and methods in accordance with the present invention."

In addition to obtaining background information on this patent, NewsRx editors also obtained the inventors' summary information for this patent: "In one embodiment, a surgical device comprises an elongate shaft having an outer tube and an inner rod positioned in the outer tube. The outer tube and inner rod each comprise a distal end and a proximal end. An actuator is operably connected to the proximal ends of the outer tube and the inner rod. An end effector is adapted for in vivo attachment to and detachment from the elongate shaft. The end effector comprises an outer casing comprising a first detent mating feature adapted to engage the distal end of the outer tube; an inner shuttle axially moveable relative the outer casing, the shuttle comprising a second detent mating feature adapted to engage the distal end of the inner rod; and a pair of surgical jaws having an opened position and closed position dependant on the relative axial position of the shuttle and casing. A tubular loader is sized to receive the end effector, the tubular loader comprising third detent mating feature adapted engage end effector.

"The first, second, and third detent mating features may have a threshold disengagement force $F_{sub.1}$, $F_{sub.2}$, and $F_{sub.3}$, respectively, of the following relative magnitudes: $F_{sub.1} < F_{sub.3} < F_{sub.2}$. The first detent mating feature may comprise a leaf spring on the outer casing adapted to engage a notch on the outer tube. The third detent mating feature may comprise a leaf spring on the tubular loader adapted to engage a notch on the outer casing. The second detent mating feature may comprise a pair of proximally oriented prongs, each having a medially oriented tooth adapted to engage a notch on the inner rod. The distal end of the outer tube may comprise a sloped surface adapted to engage and laterally spread the prongs thereby disengaging the teeth from the notch on the inner rod.

"In another embodiment, a surgical device comprises an elongate shaft comprising an outer tube and an inner rod positioned in the outer tube, the outer tube and inner rod each comprising a distal end and a proximal end. An actuator is operably connected to the proximal ends of the outer tube and the inner rod. An end effector is adapted for in vivo attachment to and detachment from the elongate shaft. The end effector comprises an outer casing comprising a first detent mating feature adapted to engage the distal end of the outer tube; an inner shuttle axially moveable relative the outer casing, the shuttle comprising a second detent mating feature adapted to engage the distal end of the inner rod; and a pair of surgical jaws having an opened position and closed position dependant on the relative axial position of the shuttle and casing. The second mating feature comprises a pair of proximally oriented prongs, each having a medially oriented tooth adapted to engage a notch on the inner rod. The distal end of the outer tube comprises a sloped surface adapted to engage and laterally spread the prongs thereby disengaging the teeth from the notch on the inner rod. The first mating feature may comprise a detent mechanism.

"In yet another embodiment, a surgical device comprises an elongate shaft comprising an outer tube and an inner rod positioned in the outer tube, the outer tube and inner rod each comprising a distal end and a proximal end. An actuator is operably connected to the proximal ends of the outer tube and the inner rod. An end effector is adapted for in vivo attachment to and detachment from the elongate shaft. The end effector comprises an outer casing and a means to attach the outer casing to the outer tube; an inner shuttle axially moveable relative the outer casing and a means to attach the shuttle to the inner rod; and a pair of surgical jaws having an opened position and closed position dependant on the relative axial position of the shuttle and casing. A tubular loader is sized to receive the end effector and includes a means..."
to attach the end effector in the tubular loader."

Janssen Biotech, Inc.

Patent Issued for Differentiation of Human Embryonic Stem Cells (USPTO 9528090)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- According to news reporting originating from Alexandria, Virginia, by NewsRx journalists, a patent by the inventor Rezania, Alireza (Skillman, NJ), filed on August 17, 2011, was published online on December 27, 2016.

The assignee for this patent, patent number 9528090, is Janssen Biotech, Inc. (Horsham, PA).

Reporters obtained the following quote from the background information supplied by the inventors: "Advances in cell-replacement therapy for Type I diabetes mellitus and a shortage of transplantable islets of Langerhans have focused interest on developing sources of insulin-producing cells, or \( \beta \) cells, appropriate for engraftment. One approach is the generation of functional \( \beta \) cells from pluripotent stem cells, such as, for example, embryonic stem cells.

"In vertebrate embryonic development, a pluripotent cell gives rise to a group of cells comprising three germ layers (ectoderm, mesoderm, and endoderm) in a process known as gastrulation. Tissues such as, for example, thyroid, thymus, pancreas, gut, and liver, will develop from the endoderm, via an intermediate stage. The intermediate stage in this process is the formation of definitive endoderm. Definitive endoderm cells express a number of markers, such as, HNF3 beta, GATA4, MIXL1, CXCR4 and SOX17.

"Formation of the pancreas arises from the differentiation of definitive endoderm into pancreatic endoderm. Cells of the pancreatic endoderm express the pancreatic-duodenal homeobox gene, PDX1. In the absence of PDX1, the pancreas fails to develop beyond the formation of ventral and dorsal buds. Thus, PDX1 expression marks a critical step in pancreatic organogenesis. The mature pancreas contains, among other cell types, exocrine tissue and endocrine tissue. Exocrine and endocrine tissues arise from the differentiation of pancreatic endoderm.

"Cells bearing the features of islet cells have reportedly been derived from embryonic cells of the mouse. For example, Lumelsky et al. (Science 292:1389, 2001) report differentiation of mouse embryonic stem cells to insulin-secreting structures similar to pancreatic islets. Soria et al. (Diabetes 49:157, 2000) report that insulin-secreting cells derived from mouse embryonic stem cells normalize glycemia in streptozotocin-induced diabetic mice.

"In one example, Hori et al. (PNAS 99: 16105, 2002) disclose that treatment of mouse embryonic stem cells with inhibitors of phosphoinositide 3-kinase (LY294002) produced
cells that resembled β-cells.

"In another example, Blyszczuk et al. (PNAS 100:998, 2003) reports the generation of insulin-producing cells from mouse embryonic stem cells constitutively expressing Pax4.

"Micallef et al. reports that retinoic acid can regulate the commitment of embryonic stem cells to form PDX1 positive pancreatic endoderm. Retinoic acid is most effective at inducing Pdx1 expression when added to cultures at day 4 of embryonic stem cell differentiation during a period corresponding to the end of gastrulation in the embryo (Diabetes 54:301, 2005).

"Miyazaki et al. reports a mouse embryonic stem cell line over-expressing Pdx1. Their results show that exogenous Pdx1 expression clearly enhanced the expression of insulin, somatostatin, glucokinase, neurogenin3, p48, Pax6, and Hnf6 genes in the resulting differentiated cells (Diabetes 53: 1030, 2004).

"Skoudy et al. reports that activin A (a member of the TGF-β superfamily) upregulates the expression of exocrine pancreatic genes (p48 and amylase) and endocrine genes (Pdx1, insulin, and glucagon) in mouse embryonic stem cells. The maximal effect was observed using 1 nM activin A. They also observed that the expression level of insulin and Pdx1 mRNA was not affected by retinoic acid; however, 3 nM FGF7 treatment resulted in an increased level of the transcript for Pdx1 (Biochem. J. 379: 749, 2004).

"Shiraki et al. studied the effects of growth factors that specifically enhance differentiation of embryonic stem cells into PDX1 positive cells. They observed that TGF-β2 reproducibly yielded a higher proportion of PDX1 positive cells (Genes Cells. 2005 June; 10(6): 503-16.).

"Gordon et al. demonstrated the induction of brachyury [positive]/HNF3 beta [positive] endoderm cells from mouse embryonic stem cells in the absence of serum and in the presence of activin along with an inhibitor of Wnt signaling (US 2006/003446A1).

"Gordon et al. (PNAS, Vol 103, page 16806, 2006) states 'Wnt and TGF-β/nodal/activin signaling simultaneously were required for the generation of the anterior primitive streak'.

"However, the mouse model of embryonic stem cell development may not exactly mimic the developmental program in higher mammals, such as, for example, humans.

"Thomson et al. isolated embryonic stem cells from human blastocysts (Science 282:114, 1998). Concurrently, Gearhart and coworkers derived human embryonic germ (hEG) cell lines from fetal gonadal tissue (Shamblott et al., Proc. Natl. Acad. Sci. USA 95:13726, 1998). Unlike mouse embryonic stem cells, which can be prevented from differentiating simply by culturing with Leukemia Inhibitory Factor (LIF), human embryonic stem cells must be maintained under very special conditions (U.S. Pat. No. 6,200,806; WO 99/20741; WO 01/51616).

"D'Amour et al. describes the production of enriched cultures of human embryonic stem cell-derived definitive endoderm in the presence of a high concentration of activin and low serum (Nature Biotechnology 2005). Transplanting these cells under the kidney capsule of mice resulted in differentiation into more mature cells with characteristics of some endodermal organs. Human embryonic stem cell-derived definitive endoderm cells can be further differentiated into PDX1 positive cells after addition of FGF-10 (US 2005/0266554A1).

"D'Amour et al. (Nature Biotechnology--24, 1392-1401 (2006)) states: 'We have developed a differentiation process that converts human embryonic stem (hES) cells to endocrine cells capable of synthesizing the pancreatic hormones insulin, glucagon, somatostatin, pancreatic polypeptide and ghrelin. This process mimics in vivo pancreatic organogenesis by directing cells through stages resembling definitive endoderm, gut-tube endoderm, pancreatic
endoderm and endocrine precursor en route to cells that express endocrine hormones'.

"In another example, Fisk et al. reports a system for producing pancreatic islet cells from human embryonic stem cells (US2006/0040387A1). In this case, the differentiation pathway was divided into three stages. Human embryonic stem cells were first differentiated to endoderm using a combination of sodium butyrate and activin A. The cells were then cultured with TGF-.beta. antagonists such as Noggin in combination with EGF or betacellulin to generate PDX1 positive cells. The terminal differentiation was induced by nicotinamide.

"There still remains a significant need to develop in vitro methods to generate a functional insulin expressing cell, that more closely resemble a .beta. cell. The present invention takes an alternative approach to improve the efficiency of differentiating human embryonic stem cells toward insulin expressing cells, by generating a population of cells wherein greater than 85% of the cells in the population express markers characteristic of the definitive endoderm lineage."

In addition to obtaining background information on this patent, NewsRx editors also obtained the inventor's summary information for this patent: "In one embodiment, the present invention provides a population of cells, wherein greater than 85% of the cells in the population express markers characteristic of the definitive endoderm lineage.

"In embodiment, populations of pluripotent stem cells are differentiated into populations of cells expressing markers characteristic of the definitive endoderm lineage by culturing the pluripotent stem cells in medium supplemented with BSA and a factor selected from the group consisting of insulin and IGF-1. In one embodiment, differentiation of the population of pluripotent stem cells toward a population of cells expressing markers characteristic of the definitive endoderm lineage is achieved by treating the pluripotent stem cells with activin A and a Wnt ligand.

"In one embodiment, differentiation of the population of pluripotent stem cells toward a population of cells expressing markers characteristic of the definitive endoderm lineage is achieved by treating the pluripotent stem cells with GDF-8 and at least one other factor is selected from the group consisting of: aniline-pyridinotriazine, a cyclic aniline-pyridinotriazine, N-[1-(Phenylmethyl)azepan-4-yl]methyl-2-pyridin-3-ylacetamide, 4-[4-(4-[2-(Pyridin-2-ylamino)ethyl]amino-1,3,5-triazin-2-yl)pyridin-2-yl]oxybutan-1-ol, 3-(3-[4-(2-[Methyl(pyridin-2-ylamino)ethylamino]-1,3,5-triazin-2-yl]p- yridin-2-ylamino)propan-1-ol, N.about.4.about.-[2-(3-Fluorophenyl)ethyl]-N.about.2.about.-[3-(4-methylp-iperazin-1-yl) propyl]pyrido[2,3-d]pyrimidine-2,4-diamine, 1-Methyl-N-[4-(pyridin-3-yl-2-[3- (trifluoromethyl)phenyl]amino-1,3-thiazol-5-yl)ethyl]piperidine-4-carboxamide, 1,1-Dimethyllethyl[2-(4-[3-(3-hydroxypropyl)phenyl]-4H-1,2,4-triazol-3- -ylamino)phenyl] ethylcarbamate, 1,1-Dimethyllethyl[3-(5-[3-(hydroxypropyl)-2-(methylxy)phenyl]-1,3-oxazol-2-ylamino)phenyl]methylcarbamate, 1-(5-[6-(4-((4-Methylpiperazin-1yl)sulfonyl) phenylamino)pyrazin-2-yl]- thiophen-2-ylmethyl)piperidin-4-ol, 1-(4-[6-(4-((4-Methylpiperazin-1-yl)sulfonyl) phenylamino)pyrazin-2-yl]- thiophen-2-ylmethyl)piperidin-4-carboxamide, and 2-[4-(1-Methyllethyl)phenyl]amino-N-(2-thiophen-2-ylethyl)-7,8-dihydropy- rido[4,3-d] pyrimidine-6(5H)-carboxamide."

SUNNYBROOK RESEARCH INSTITUTE

Patent Issued for Electrode Designs for Efficient Neural Stimulation (USPTO 9526890)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- From Alexandria, Virginia, NewsRx journalists report that a patent by the inventors Golestanirad, Laleh (Brookline, MA); Graham, Simon J. (Toronto, CA), filed on April 10, 2015, was published online on December 27, 2016.

The patent's assignee for patent number 9526890 is SUNNYBROOK RESEARCH INSTITUTE (Toronto, Ontario, CA).

News editors obtained the following quote from the background information supplied by the inventors: "Electrical stimulation of the nervous system is a technique used for restoring function to individuals with various diseases or impairments. Planar electrodes in particular are being increasingly used in neuro-stimulator devices for stimulating the central and peripheral nervous systems in humans.

"Epidural spinal cord stimulation (ESCS), for example, includes electrical stimulation to the dorsal roots and/or the dorsal columns of the spinal cord. ESCS can be used for treating pain associated with various syndromes. Recently the combination of ESCS and partial weight bearing therapy has been shown to induce significant functional gains in the over-ground gait of individuals with chronic, incomplete spinal cord injury and with very low motor scores in their lower limbs.

"Epidural cortical stimulation (ECS) is used in the brain for transferring electrical stimulation via planar electrodes for therapeutic applications. ECS can be used for the treatment of a variety of disorders, such as neuropathic pain, movement disorders, Parkinson's disease, and stroke rehabilitation.

"Another application of electrical stimulation of the nervous system is transcranial direct current stimulation (tDCS). tDCS is a non-invasive, painless, safe and portable technique that has been found to modulate cortical excitability. The tDCS procedure is simple and economical--that is, the procedure is an injection of a weak DC current (less than 2 mA) between the surface electrodes that are connected to a stimulation device. tDCS has also shown promising results as a potential therapy in stroke, Parkinson's disease, depression and epilepsy. The advantages of tDCS, along with its positive results, reinforce its applicability within the clinical practice.

"Planar electrodes are also used in electrical stimulation for restoring and/or improving control of bladder functions. In cases of neurological diseases, for example, promising results have been shown in the restoration of continence and micturition.

"Deep brain stimulation (DBS) is another application of electrical stimulation of the nervous system. DBS involves high frequency electrical stimulation of the thalamic or basal ganglia structures (e.g., subthalamic nucleus (STN) or an internal segment of the globus pallidus) for the treatment of movement disorders. DBS is rapidly emerging as an alternative to surgical lesions.

"The most widely used medical implanted electrodes are those used in artificial cardiac pacemaker devices to apply electric currents to the muscles of the human heart. The
primary purpose of these devices is to maintain an adequate pace and rhythm of the heart's contractions. These devices have been used since the 1960s in millions of patients around the world.

As a supplement to the background information on this patent, NewsRx correspondents also obtained the inventors' summary information for this patent: "In a broad aspect, there is provided an electrode for neural stimulation, the electrode comprising: an electrically conductive body, the body having a generally planar core portion, wherein the generally planar core portion has a plurality of holes therein, and wherein the plurality of holes has one or more internal perimeters.

"In some cases, each of the one or more internal perimeters comprises at least three edges and at least three vertices, each edge being joined to its adjacent edges at a respective one of the at least three vertices. In some cases, the at least three edges define a non-180.degree. angle at each vertex in the at least three vertices.

"In some cases, respective edges and vertices of the plurality of holes are configured to reduce a capacity dimension of a surface of the core portion to less than 2.

"In some cases, each of the one or more internal perimeters comprise at least twelve edges and at least twelve vertices. In some cases, the plurality of holes form a Sierpinski triangle of at least order 2.

"In some cases, each of the one or more internal perimeters comprise at least thirty-six edges and at least thirty-six vertices. In some cases, the plurality of holes form a Sierpinski square of at least order 2.

"In some cases, each of the plurality of holes has a perimeter shape that is self-similar to a perimeter shape of the generally planar core portion.

"In some cases, the generally planar core portion has a base shape that corresponds to a regular polygon having n sides. In some cases, n is at least three. In some cases, n is at least four.

"In some cases, a shape of the generally planar core portion is obtainable from a base shape that corresponds to a regular polygon having n sides by removing a first order smaller regular polygon having n sides from the interior of the base shape to provide a first order hole in the plurality of holes, the first order hole having n edges. In some cases, the shape is further obtainable by removing a plurality of k-th order smaller regular polygons having n sides from the interior of the base shape to provide a plurality of k-th order holes in the plurality of holes, each of the plurality of k-th order holes having n edges. In some cases, the shape is further obtainable by repeatedly removing the plurality of k-th order smaller regular polygons for two or more integer values of k. In some cases, the shape is further obtainable by dividing an area of the first order smaller regular polygon into a plurality of second order smaller regular polygons having n sides, and attaching the second order smaller regular polygons to one or more selected edges of the shape. In some cases, the shape is further obtainable by dividing an area of each of the plurality of k-th order smaller regular polygons to provide (k+1)-th order smaller regular polygons having n sides, and attaching the (k+1)-th order smaller regular polygons to an edge of the shape.

"In some cases, n is at least three. In some cases, n is at least four. In some cases, n is at least 20, and the generally planar core portion approximates a closed curve in shape.

"In some cases, k is between 2 and 5. In some cases, k is between 3 and 5.

"In some cases, the generally planar core portion forms a closed curve in shape, and wherein each of the plurality of holes forms a closed curve in shape. In some cases, a shape of the generally planar core portion is obtainable from a base shape that corresponds to a closed curve by removing a first order smaller closed curve from the interior of the base shape to
provide a first order hole in the plurality of holes. In some cases, the shape is further obtainable by removing a plurality of k-th order smaller closed curves from the interior of the base shape to provide a plurality of k-th order holes in the plurality of holes. In some cases, the shape is further obtainable by repeatedly removing the plurality of k-th order smaller closed curves for two or more integer values of k.

"In some cases, the generally planar core portion is curved.

"In some cases, the generally planar core portion is flexible.

"In another broad aspect, there is provided an electrode for neural stimulation, the electrode comprising: an electrically conductive body, the body having a core portion for increasing a neural activation function in a tissue, at a distance of 5 mm from a surface of the electrode, wherein an absolute value of the neural activation function is increased between 2 and 10 times relative to a solid surface electrode of equivalent area.

"In some cases, the neural activation function is increased in a direction orthogonal to the surface of the electrode.

"In some cases, the electrode is an ESCS electrode. In some cases, the electrode is an ECS electrode. In some cases, the electrode is a tDCS electrode. In some cases, the electrode is a DBS electrode. In some cases, the electrode is a cardiac pacemaker electrode."

COVIDIEN LP

Patent Issued for Electrosurgical Instrument (USPTO 9526569)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- COVIDIEN LP (Mansfield, MA) has been issued patent number 9526569, according to news reporting originating out of Alexandria, Virginia, by NewsRx editors.

The patent's inventors are Brannan, Joseph D. (Lyons, CO); Ladtkow, Casey M. (Erie, CO).

This patent was filed on November 30, 2015 and was published online on December 27, 2016.

From the background information supplied by the inventors, news correspondents obtained the following quote: "Technical Field

"The present disclosure relates to an electrosurgical instrument. More particularly, the present disclosure relates to a directional microwave energy instrument configured to electrosurgically treat tissue in two modes of operation; a first mode of operation to
electrosurgically treat tissue; and a second mode of operation to dissect the tissue.

"Description of Related Art

"Standard surgical procedures for trauma, cancer and transplants in the kidney, liver, and like organs have several key shortcomings affecting efficacy, morbidity and mortality. In an effort to fully remove or resect an organ, the surgeon may be forced to breach the tissue causing a large amount of bleeding. Careful hemostasis can minimize blood loss and complications but is laborious and time consuming using the systems and methods known in the art. Uncontrollable bleeding, for example, is one of the leading causes that prevent such treatments from being offered to patients with cirrhotic livers.

"Typical methods for creating resections and/or controlling bleeding and blood loss include scalpels, electrocautery, ultrasonic scalpels, argon beam coagulators, and radio frequency (RF) surface dissectors. Typically, a surgeon utilizes one of the aforementioned therapies, e.g., a scalpel, for creating resections and another one of the aforementioned therapies, e.g., an argon beam coagulator, to control bleeding. These therapies, however, in their present form have one or more potential drawbacks, such as, for example, a complete lack or partial inability to create a hemostatic or near-hemostatic resection plane with any significant depth (e.g., the devices utilized to control bleeding, typically, create a small footprint)."

Supplementing the background information on this patent, NewsRx reporters also obtained the inventors' summary information for this patent: "As can be appreciated, a directional microwave and radio frequency energy instrument that is configured to electrosurgically treat tissue in two modes of operation to resect and dissect tissue may prove useful in the medical arts.

"Embodiments of the present disclosure are described in detail with reference to the drawing figures wherein like reference numerals identify similar or identical elements. As used herein, the term 'distal' refers to the portion that is being described which is further from a user, while the term 'proximal' refers to the portion that is being described which is closer to a user.

"An aspect of the present disclosure provides an electrosurgical instrument. The electrosurgical instrument includes an elongated housing having proximal and distal ends. The proximal end configured to couple to a source of electrosurgical energy via first and second channels extending along a length of the housing to the distal end thereof. The distal end including a reflector having a dielectric load operably coupled thereto and configured to receive at least a portion of the first channel therein. In a first mode of operation electrosurgical energy is transmitted to the first channel and reflected from the reflector to electrosurgically treat tissue. The reflector is configured to receive at least a portion of the second channel therein. In a second mode of operation electrosurgical energy transmitted to the second channel to dissect tissue. The reflector may be formed from a conductive metal tube having a diagonal cross-cut at least partially through a width thereof.

"The dielectric load may be shaped to complement a shape of the reflector. The dielectric load may be made from a material including, but not limited to ceramic, fluid and plastic. The dielectric load may include at least one aperture therein that is configured to receive at least a portion of the coaxial feed therein.

"In certain instances, the first channel is in the form of a coaxial feed that includes an outer conductor, a dielectric extending past the outer conductor and an inner conductor extending past both the outer conductor and dielectric. In this instance, the inner conductor does not extend past the reflector.

"In certain instances, the second channel may be in the form of an electrical lead including a monopolar electrode. In this instance, the monopolar electrode may be disposed at a distal tip of the reflector."
"In certain instances, the electrosurgical instrument may also include a microwave block that is operably coupled to the distal end of the electrosurgical instrument adjacent the dielectric load. In this particular instance, the microwave block includes a dielectric distal portion and a conductive proximal portion. The microwave block may be configured to prevent electrosurgical energy from exiting a distal side of the reflector when the electrosurgical instrument is in the first mode of operation. The dielectric portion of the microwave block may include a dielectric constant that is less than a dielectric constant of the dielectric load of the distal end.

"In certain instances, the electrosurgical instrument may also include a switch assembly that is supported on the housing and configured to place the electrosurgical instrument into the first and second modes of operation.

"In certain instances, the electrosurgical instrument may also include a cooling assembly that operably couples to the electrosurgical instrument and circulates at least one coolant through the electrosurgical instrument to prevent the reflector and electrode from exceeding a predetermined temperature.

"In certain instances, the electrosurgical instrument may also include a sensor assembly that is configured to detect when the electrosurgical instrument contacts tissue. In this instance, the sensor assembly may be an optical sensor assembly, electrode impedance sensor assembly and acoustic transducer response assembly.

"An aspect of the present disclosure provides an electrosurgical instrument. The electrosurgical instrument includes an elongated housing having proximal and distal ends. The proximal end is configured to couple to a source of electrosurgical energy via first and second channels extending along a length of the housing to the distal end thereof. A switch assembly is supported on the housing and is configured to place the electrosurgical instrument into first and second modes of operation. A reflector operably disposed at the distal end of the housing has a tapered configuration and is configured to provide an energy pattern in tissue proportional to a depth of the taper of the reflector. A dielectric load is shaped to complement a shape of the reflector for coupling the dielectric load to the reflector. The dielectric load is configured to receive at least a portion of the first channel therein. In the first mode of operation electrosurgical energy transmitted to the first channel is reflected from the reflector to electrosurgically treat tissue. The reflector is configured to receive at least a portion of the second channel therein. In the second mode of operation electrosurgical energy transmitted to the second channel to dissect tissue.

"The dielectric load may be made from a material including, but not limited to ceramic, fluid and plastic. The dielectric load may include at least one aperture therein that is configured to receive at least a portion of the coaxial feed therein.

"In certain instances, the first channel may be in the form of a coaxial feed that includes an outer conductor, a dielectric extending past the outer conductor and an inner conductor extending past both the outer conductor and dielectric. In this instance, the inner conductor does not extend past the reflector.

"In certain instances, the second channel may be in the form of an electrical lead including a monopolar electrode. In this instance, the monopolar electrode may be disposed at a distal tip of the reflector.

"In certain instances, the electrosurgical instrument may also include a microwave block that is operably coupled to the distal end of the electrosurgical instrument adjacent the dielectric load. In this particular instance, the microwave block includes a dielectric distal portion and a conductive proximal portion. The microwave block may be configured to shape electrosurgical energy exiting a distal side of the reflector and improve efficiency of the
electrosurgical instrument when the electrosurgical instrument is in the first mode of operation. The dielectric portion of the microwave block may include a dielectric constant that is less than a dielectric constant of the dielectric load of the distal end."

HITACHI METALS, LTD.

Patent Issued for External Fixation Device and Fixation Device Set (USPTO 9526523)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- From Alexandria, Virginia, NewsRx journalists report that a patent by the inventors Aoki, Masaaki (Takasaki, JP); Ochi, Mitsuo (Hiroshima, JP), filed on June 11, 2013, was published online on December 27, 2016.

The patent's assignee for patent number 9526523 is HITACHI METALS, LTD. (Tokyo, JP).

News editors obtained the following quote from the background information supplied by the inventors: "Extensive articular cartilage damage is treated typically by making a small hole in the damaged area using a drill, or an awl to stimulate bleeding from bone marrow thereby introducing bone marrow mesenchymal cells into the joint. Applying a load, however, to the damaged part soon after the operation poses a risk of damaging still immature tissues.

"Patent Literature 1 discloses an example of an external fixation device which can be utilized in such a treatment of an articular cartilage damage. The external fixation device includes ball joints and a gear box, sandwiches the joint and mechanically fixes two sides of the joint in order to protect the damaged part, so that joint bone parts are separated from each other and the damaged part will have a reduced load. Then, with the external fixation device attached, the patient moves the joint."

As a supplement to the background information on this patent, NewsRx correspondents also obtained the inventors' summary information for this patent: "Technical Problem

"However, the external, fixation device disclosed in Patent Literature 1 includes a large number of parts and has a complicated structure.

"Patent Literature 2 discloses an external fixation device which includes a magnet. However, in this external fixation device, a pair of magnetic bodies, one of which fixed to a first bone portion and the other fixed to a second bone portion, contract to each other when the device is used, and cannot be utilized in treating an articular cartilage damage where the first bone portion and the second bone portion in a joint must be separated from each other.

"Therefore, a primary object of the present invention is to provide an external fixation device which includes a decreased number of parts and has a simple structure yet is
capable of separating a first bone portion and a second bone portion from each other in a joint thereby making possible to effectively treating the articular cartilage damage; and to provide a fixation device set.

"Solution to Problem

"According to an aspect of the present invention, there is provided an external fixation device for keeping a first bone portion and a second bone portion separated from each other in a joint, by attaching to a first pin which penetrates the first bone portion and to a second pin which penetrates the second bone portion. The device includes a first permanent magnet and a second permanent magnet which are opposed to each other, with their same poles facing each other; a first holding portion which is disposed on a surface of the first permanent magnet, on a side facing away from a surface opposing to the second permanent magnet, and is attached to the first pin; a second holding portion which is disposed on a surface of the second permanent magnet, on a side facing away from a surface opposing to the first permanent magnet, and is attached to the second pin; and a pair of first limiter portions which allow movement of the first permanent magnet and the second permanent magnet in a first direction defined as a direction of their repulsion force by sandwiching the first permanent magnet and the second permanent magnet from a second direction defined as a direction perpendicular to the first direction, and limit movement thereof in the second direction.

"In the present invention, the first permanent magnet and the second permanent magnet are disposed with their same poles opposed to each other, and a pair of first limiter portions sandwich the first permanent magnet and the second permanent magnet. Therefore, the first permanent magnet and the second permanent magnet repulse against each other, moving away from each other in the direction of the repulsion force, i.e., in the first direction. As a result, the first pin which is connected to the first permanent magnet via the first holding portion, and the second pin which is connected to the second permanent magnet via the second holding portion, move away from each other. This makes it possible to move a joint, with its first bone portion and second bone portion kept apart from each other, i.e., with the cartilage part of the cleft between articulations kept open. By utilizing the repulsion force between the first permanent magnet and the second permanent magnet as described above, it becomes possible to reduce the number of parts and simplify the structure, and therefore, it becomes possible to reduce a load to the damaged area of the articular cartilage (cartilage part under regeneration) and to effectively treat the articular cartilage damage. In other words, it becomes possible to obtain an external fixation device which includes a decreased number of parts and has a simple structure yet is capable of effectively treating the articular cartilage damage.

"Preferably, the external fixation device further includes a second limiter portion disposed to connect the pair of first limiter portions to each other to limit movement of the first permanent magnet and the second permanent magnet in a third direction defined as a direction perpendicular to both of the first direction and the second direction. In this case, it becomes possible to limit movement of the first permanent magnet and the second permanent magnet in the third direction which is the direction perpendicular to both of the first direction and the second direction. This prevents the first permanent magnet and the second permanent magnet from becoming twisted to each other, thereby providing a smoother linear reciprocating relative movement between the first permanent magnet and the second permanent magnet.

"Further preferably, the second limiter portion includes a magnetic member. In this case, the arrangement makes it possible to reduce a leakage magnetic field around the external fixation device. Therefore, the arrangement makes it possible to reduce adverse effect to the surrounds.

"Further, preferably, the external fixation device includes a ball joint for attaching at
least one of the first holding portion and the second holding portion to a corresponding one of the first pin and the second pin. In this case, at least one of the first holding portion and the second holding portion is attached to the corresponding pin(s) via the ball joint. Therefore, the arrangement allows simultaneous, relative stretching/contracting and pivoting movements between components on the first holding portion side and those on the second holding portion side of the external fixation device. Hence, the external fixation device is capable of following bending and stretching or pivoting movements of the joint, and the patient can move the joint freely. As a result, the joint can be moved smoothly, with a further reduced load onto the articular cartilage damage area (cartilage part under regeneration), making it possible to treat extensive articular cartilage damage more effectively.

"Preferably, the second holding portion is connected to the ball joint, whereas, the first holding portion has a through-hole for insertion of the first pin. In this case, the first holding portion can be attached easily to the first pin by inserting the first pin through the through-hole of the first holding portion, and by attaching the second holding portion to the second pin via the ball joint, the joint can be moved smoothly.

"Further preferably, at least one of the first holding portion and the second holding portion has a through-hole for insertion of the corresponding one of the first pin and the second pin. In this case, by inserting a corresponding pin(s), through the through-hole(s) of at least one of the first holding portion and the second holding portion, the holding portion is attached easily to the pin.

"Further, preferably, the external fixation device includes a slanted sleeve fitted into the through-hole. In this case, by fitting the slanted sleeve into the through-hole of the holding portion, the pin which penetrates the through-hole is oriented in a slanted direction. Therefore, it is possible to insert the pin into an area of the bone portion which has a high density of bone, depending on specific conditions of individual patients.

"Preferably, the pair of first limiter portions and the first holding portion are integral with each other. In this case, the arrangement further reduces the number of parts in the external fixation device.

"Further preferably, each of the first permanent magnet and the second permanent magnet is rectangular parallelepiped. In this case, it is possible to obtain a large repulsion force with a simple shape at reduced cost.

"According to another aspect of the present invention, there is provided a fixation device set which includes the above-described external fixation device for attaching to the first pin and the second pin on their common one end-side; and a pin fixture for attaching to the first pin and the second pin on their common another end-side. The pin fixture includes a fixture main body; a first connecting portion for connecting the fixture main body to the first pin; and a second connecting portion for connecting the fixture main body to the second pin.

"According to the present invention, the external fixation device is attached to a common one end-side of the first pin which penetrates the first bone portion and the second pin which penetrates the second bone portion, whereas the pin fixture is attached to the other common end-side of the first pin and the second pin. The arrangement reduces unnecessary movement of the first pin and the second pin, thereby reducing damage to the bone portions. This works effectively, especially for patients having a low density of bone. As described, it becomes possible to obtain the fixation device set which includes a decreased number of parts and has a simple structure yet is capable effectively treating the articular cartilage damage.

"Preferably, the first connecting portion is pivotable with respect to the fixture main body, whereas the second connecting portion is linearly movable with respect to the fixture main body. In this case, therefore, even if there happens to be variations in the position of the first pin
and the second pin on the pin fixture side as viewed from the joint, it is possible to allow for
such variations and keep holding the other end-side of the first pin and the second pin.

"The above-described object and other objects, characteristics, aspects and
advantages of the present invention will become clearer from the following detailed description
of embodiments of the present invention to be made with reference to the attached drawings."

NYXOA SA

Patent Issued for External Resonance Matching between an Implanted
Device and an External Device (USPTO 9526906)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness
& Wellness Week -- From Alexandria, Virginia, NewsRx journalists report that a patent by the
inventor Mashiach, Adi (Tel Aviv, IL), filed on July 26, 2013, was published online on
December 27, 2016.

The patent's assignee for patent number 9526906 is NYXOA SA (Mont-st-Guibert,
BE).

News editors obtained the following quote from the background information
supplied by the inventors: "Neural modulation presents the opportunity to treat many
physiological conditions and disorders by interacting with the body's own natural neural
processes. Neural modulation includes inhibition (e.g., blockage), stimulation, modification,
regulation, or therapeutic alteration of activity, electrical or chemical, in the central, peripheral,
or autonomic nervous system. By modulating the activity of the nervous system, for example
through the stimulation of nerves or the blockage of nerve signals, several different goals may
be achieved. Motor neurons may be stimulated at appropriate times to cause muscle
contractions. Sensory neurons may be blocked, for instance to relieve pain, or stimulated, for
instance to provide a signal to a subject. In other examples, modulation of the autonomic
nervous system may be used to adjust various involuntary physiological parameters, such as
heart rate and blood pressure. Neural modulation may provide the opportunity to treat several
diseases or physiological conditions, a few examples of which are described in detail below.

"Among the conditions to which neural modulation may be applied is obstructive
sleep apnea (OSA). OSA is a respiratory disorder characterized by recurrent episodes of partial
or complete obstruction of the upper airway during sleep. During the sleep of a person without
OSA, the pharyngeal muscles relax during sleep and gradually collapse, narrowing the airway.
The airway narrowing limits the effectiveness of the sleeper's breathing, causing a rise in
CO.sub.2 levels in the blood. The increase in CO.sub.2 results in the pharyngeal muscles
contracting to open the airway to restore proper breathing. The largest of the pharyngeal
muscles responsible for upper airway dilation is the genioglossus muscle, which is one of
several different muscles in the tongue. The genioglossus muscle is responsible for forward
tongue movement and the stiffening of the anterior pharyngeal wall. In patients with OSA, the neuromuscular activity of the genioglossus muscle is decreased compared to normal individuals, accounting for insufficient response and contraction to open the airway as compared to a normal individual. This lack of response contributes to a partial or total airway obstruction, which significantly limits the effectiveness of the sleeper's breathing. In OSA patients, there are often several airway obstruction events during the night. Because of the obstruction, there is a gradual decrease of oxygen levels in the blood (hypoxemia). Hypoxemia leads to night time arousals, which may be registered by EEG, showing that the brain awakes from any stage of sleep to a short arousal. During the arousal, there is a conscious breath or gasp, which resolves the airway obstruction. An increase in sympathetic tone activity rate through the release of hormones such as epinephrine and noradrenaline also often occurs as a response to hypoxemia. As a result of the increase in sympathetic tone, the heart enlarges in an attempt to pump more blood and increase the blood pressure and heart rate, further arousing the patient. After the resolution of the apnea event, as the patient returns to sleep, the airway collapses again, leading to further arousals.

"These repeated arousals, combined with repeated hypoxemia, leaves the patient sleep deprived, which leads to daytime somnolence and worsens cognitive function. This cycle can repeat itself up to hundreds of times per night in severe patients. Thus, the repeated fluctuations in and sympathetic tone and episodes of elevated blood pressure during the night evolve to high blood pressure through the entire day. Subsequently, high blood pressure and increased heart rate may cause other diseases.

"Efforts for treating OSA include Continuous Positive Airway Pressure (CPAP) treatment, which requires the patient to wear a mask through which air is blown into the nostrils to keep the airway open. Other treatment options include the implantation of rigid inserts in the soft palate to provide structural support, tracheotomies, or tissue ablation.

"Another condition to which neural modulation may be applied is the occurrence of migraine headaches. Pain sensation in the head is transmitted to the brain via the occipital nerve, specifically the greater occipital nerve, and the trigeminal nerve. When a subject experiences head pain, such as during a migraine headache, the inhibition of these nerves may serve to decrease or eliminate the sensation of pain.

"Neural modulation may also be applied to patients with hypertension. Blood pressure in the body is controlled via multiple feedback mechanisms. For example, baroreceptors in the carotid body in the carotid artery are sensitive to blood pressure changes within the carotid artery. The baroreceptors generate signals that are conducted to the brain via the glossopharyngeal nerve when blood pressure rises, signaling the brain to activate the body's regulation system to lower blood pressure, e.g., through changes to heart rate, and vasodilation/vasoconstriction. Conversely, parasympathetic nerve fibers on and around the renal arteries generate signals that are carried to the kidneys to initiate actions, such as salt retention and the release of angiotensin, which raise blood pressure. Modulating these nerves may provide the ability to exert some external control over blood pressure.

"The foregoing are just a few examples of conditions to which neuromodulation may be of benefit. But the embodiments of the invention described hereafter are not necessarily limited to treating only the above-described conditions."

As a supplement to the background information on this patent, NewsRx correspondents also obtained the inventor's summary information for this patent: "Some embodiments of the disclosure may include a device for wirelessly powering an implant unit in a body of a subject from a location outside of the body of the subject, wherein the implant unit includes a secondary antenna for wirelessly receiving energy. The device may include a primary
antenna configured to be located external to the body of the subject, a circuit electrically connected to the primary antenna, and at least one processor electrically connected to the primary antenna and the circuit. The at least one processor may determine a resonant frequency mismatch between a first resonant frequency associated with the primary antenna and a second resonant frequency associated with the secondary antenna associated with the implant unit; and apply an adjustment to at least one component of the circuit to cause a change in the first resonant frequency associated with the primary antenna and a reduction in the resonant frequency mismatch.

"In some other embodiments, the device may include a primary antenna configured to be located external to a subject, a circuit electrically connected to the primary antenna and associated with a plurality of selectable capacitance values. The device may also include at least one processor configured to determine a transmission efficiency value between the primary antenna and the secondary antenna for each of a plurality of frequencies; and select a capacitance value to be included in the circuit, from among the plurality of selectable capacitance values, based on the determined transmission efficiencies.

"Additional features of the disclosure will be set forth in part in the description that follows, and in part will be obvious from the description, or may be learned by practice of the disclosed embodiments.

"It is to be understood that both the foregoing general description and the following detailed description are exemplary and explanatory only, and are not restrictive of the invention, as claimed."

Intuitive Surgical Operations, Inc.

Patent Issued for Flow Reduction Hood Systems (USPTO 9526401)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- From Alexandria, Virginia, NewsRx journalists report that a patent by the inventors Saadat, Vahid (Atherton, CA); Tam, Edmund (Mountain View, CA); Rothe, Chris A. (San Mateo, CA); Miller, David (Cupertino, CA); Peh, Ruey-Feng (Singapore, SG), filed on January 16, 2013, was published online on December 27, 2016.

The patent's assignee for patent number 9526401 is Intuitive Surgical Operations, Inc. (Sunnyvale, CA).

News editors obtained the following quote from the background information supplied by the inventors: "Conventional devices for accessing and visualizing interior regions of a body lumen are known. For example, ultrasound devices have been used to produce images
from within a body in vivo. Ultrasound has been used both with and without contrast agents, which typically enhance ultrasound-derived images.

"Other conventional methods have utilized catheters or probes having position sensors deployed within the body lumen, such as the interior of a cardiac chamber. These types of positional sensors are typically used to determine the movement of a cardiac tissue surface or the electrical activity within the cardiac tissue. When a sufficient number of points have been sampled by the sensors, a 'map' of the cardiac tissue may be generated.

"Another conventional device utilizes an inflatable balloon which is typically introduced intravascularly in a deflated state and then inflated against the tissue region to be examined. Imaging is typically accomplished by an optical fiber or other apparatus such as electronic chips for viewing the tissue through the membrane(s) of the inflated balloon. Moreover, the balloon must generally be inflated for imaging. Other conventional balloons utilize a cavity or depression formed at a distal end of the inflated balloon. This cavity or depression is pressed against the tissue to be examined and is flushed with a clear fluid to provide a clear pathway through the blood.

"However, such imaging balloons have many inherent disadvantages. For instance, such balloons generally require that the balloon be inflated to a relatively large size which may undesirably displace surrounding tissue and interfere with fine positioning of the imaging system against the tissue. Moreover, the working area created by such inflatable balloons are generally cramped and limited in size. Furthermore, inflated balloons may be susceptible to pressure changes in the surrounding fluid. For example, if the environment surrounding the inflated balloon undergoes pressure changes, e.g., during systolic and diastolic pressure cycles in a beating heart, the constant pressure change may affect the inflated balloon volume and its positioning to produce unsteady or undesirable conditions for optimal tissue imaging.

"Accordingly, these types of imaging modalities are generally unable to provide desirable images useful for sufficient diagnosis and therapy of the endoluminal structure, due in part to factors such as dynamic forces generated by the natural movement of the heart. Moreover, anatomic structures within the body can occlude or obstruct the image acquisition process. Also, the presence and movement of opaque bodily fluids such as blood generally make in vivo imaging of tissue regions within the heart difficult.

"Other external imaging modalities are also conventionally utilized. For example, computed tomography (CT) and magnetic resonance imaging (MRI) are typical modalities which are widely used to obtain images of body lumens such as the interior chambers of the heart. However, such imaging modalities fail to provide real-time imaging for intra-operative therapeutic procedures. Fluoroscopic imaging, for instance, is widely used to identify anatomic landmarks within the heart and other regions of the body. However, fluoroscopy fails to provide an accurate image of the tissue quality or surface and also fails to provide for instrumentation for performing tissue manipulation or other therapeutic procedures upon the visualized tissue regions. In addition, fluoroscopy provides a shadow of the intervening tissue onto a plate or sensor when it may be desirable to view the intraluminal surface of the tissue to diagnose pathologies or to perform some form of therapy on it.

"Moreover, many of the conventional imaging systems lack the capability to provide therapeutic treatments or are difficult to manipulate in providing effective therapies. For instance, the treatment in a patient's heart for atrial fibrillation is generally made difficult by a number of factors, such as visualization of the target tissue, access to the target tissue, and instrument articulation and management, amongst others.

"Conventional catheter techniques and devices, for example such as those described in U.S. Pat. Nos. 5,895,417; 5,941,845; and 6,129,724, used on the epicardial surface of the
heart may be difficult in assuring a transmural lesion or complete blockage of electrical signals. In addition, current devices may have difficulty dealing with varying thickness of tissue through which a transmural lesion desired.

"Conventional accompanying imaging devices, such as fluoroscopy, are unable to detect perpendicular electrode orientation, catheter movement during the cardiac cycle, and image catheter position throughout lesion formation. Without real-time visualization, it is difficult to reposition devices to another area that requires transmural lesion ablation. The absence of real-time visualization also poses the risk of incorrect placement and ablation of critical structures such as sinus node tissue which can lead to fatal consequences.

"Thus, a tissue imaging system which is able to provide real-time in vivo access to and images of tissue regions within body lumens such as the heart through opaque media such as blood and which also provides instruments for therapeutic procedures are desirable."

As a supplement to the background information on this patent, NewsRx correspondents also obtained the inventors' summary information for this patent: "The tissue-imaging apparatus described relates to variations of a device and/or method to provide real-time images in vivo of tissue regions within a body lumen such as a heart, which is filled with blood flowing dynamically therethrough. Such an apparatus may be utilized for many procedures, e.g., mitral valvuloplasty, left atrial appendage closure, arrhythmia ablation, transseptal access and patent foramen ovale closure among other procedures. Further details of such a visualization catheter and methods of use are shown and described in U.S. Pat. Pub. 2006/0184048 A1, which is incorporated herein by reference in its entirety.

"A tissue imaging and manipulation apparatus that may be utilized for procedures within a body lumen, such as the heart, in which visualization of the surrounding tissue is made difficult, if not impossible, by medium contained within the lumen such as blood, is described below. Generally, such a tissue imaging and manipulation apparatus comprises an optional delivery catheter or sheath through which a deployment catheter and imaging hood may be advanced for placement against or adjacent to the tissue to be imaged.

"The deployment catheter may define a fluid delivery lumen therethrough as well as an imaging lumen within which an optical imaging fiber or electronic imaging assembly may be disposed for imaging tissue. When deployed, the imaging hood may be expanded into any number of shapes, e.g., cylindrical, conical as shown, semi-spherical, etc., provided that an open area or field is defined by the imaging hood. The open area is the area within which the tissue region of interest may be imaged. The imaging hood may also define an atraumatic contact lip or edge for placement or abutment against the tissue region of interest. Moreover, the distal end of the deployment catheter or separate manipulatable catheters may be articulated through various controlling mechanisms such as push-pull wires manually or via computer control.

"The visualization catheter may also have one or more membranes or layers of a polymeric material which covers at least a portion of the open area. The membrane or layer may be an extension of the deployed hood or it may be a separate structure. In either case, the membrane or layer may define at least one opening which allows for fluid communication between the visualization hood and the fluid environment within which the catheter is immersed.

"In operation, after the imaging hood has been deployed, fluid may be pumped at a positive pressure through the fluid delivery lumen until the fluid fills the open area completely and displaces any blood from within the open area. When the hood and membrane or layer is pressed against the tissue region to be visualized or treated, the contact between the one or more openings and the tissue surface may help to retain the clear fluid within the hood for visualization. Moreover, the membrane or layer may help to retain the fluid within the hood.
while also minimizing any fluid leakage therefrom. Additionally, the one or more openings may also provide for direct access to the underlying tissue region to be treated by any number of tools or instruments positioned within the hood.

"The fluid may comprise any biocompatible fluid, e.g., saline, water, plasma, Fluorinert.TM., etc., which is sufficiently transparent to allow for relatively undistorted visualization through the fluid. The fluid may be pumped continuously or intermittently to allow for image capture by an optional processor which may be in communication with the assembly.

"The imaging hood may be deployed into an expanded shape and retracted within a catheter utilizing various mechanisms. Moreover, the imaging element, such as a CCD/CMOS imaging camera, may be positioned distally or proximally of the imaging hood when collapsed into its low-profile configuration. Such a configuration may reduce or eliminate friction during deployment and retraction as well as increase the available space within the catheter not only for the imaging unit but also for the hood.

"In further controlling the flow of the purging fluid within the hood, various measures may be taken in configuring the assembly to allow for the infusion and controlled retention of the clearing fluid into the hood. By controlling the infusion and retention of the clearing fluid, the introduction of the clearing fluid into the patient body may be limited and the clarity of the imaging of the underlying tissue through the fluid within the hood may be maintained for relatively longer periods of time by inhibiting, delaying, or preventing the infusion of surrounding blood into the viewing field.

"One variation for controlling the flow of the purging fluid within and from the hood may include a distensible and/or inflatable membrane which extends over the distal opening of the hood to at least partially enclose the open area or field with an aperture defined along the membrane. The aperture may be controlled to decrease or increase in size via a number of mechanisms to control the fluid rate therethrough. For instance, the aperture may be controlled by the inflation or deflation of the membrane extending over the hood opening. Other variations may utilize a membrane which is retractable over the hood to control aperture size.

"Other variations may include aperture openings having other configurations such as an aperture which is slotted transversely relative to the catheter. Such a slotted aperture may extend along the entire length of the diameter of the membrane or just along a portion thereof to facilitate access of an instrument, e.g., ablation instrument, to the underlying visualized tissue. Moreover, the aperture may also function, e.g., as a template for ablation probes to create linear ablation lesions on the contacted tissue by following the slotted aperture as well as restricting or inhibiting the flow of the purging fluid from the hood. Other variations for aperture configuration may include one or more slotted openings which extend in an arcuate or curved manner over the covering or membrane. Yet another variation may include a meshed membrane or covering over the distal opening of the hood.

"Other variations for controlling fluid flow may also include a plurality of inflatable elongate strips or barriers which extend over the opening of the hood adjacent to one another such that the entire distal opening of the hood may be closed by inflation or expansion of these strips or barriers. Yet another variation may comprise a rotatable barrier which may pivot or rotate relative to one or more stationary segments which are non-moving relative to the hood to transition between an open and closed configuration. By rotating the barrier, segmented openings may be formed between each respective adjacent segment. By fully rotating the barrier, the segmented openings may be fully opened and the size of the segmented openings formed can thus be controlled by rotating the barrier accordingly.

"In collapsing and/or deploying a hood having a flow-control aperture, one variation
for collapsing such an assembly may include use of a dilating instrument which may be advanced through the hood to engage the aperture. As the dilator is pushed further distally, the support struts supporting the hood may become straightened relative to the dilator and collapsed into a low-profile configuration. With this variation, the hood may be collapsed for delivery without having to retract the hood into a catheter sheath. Additionally, with the ability to collapse the hood distally rather than proximally, the projecting tip of the dilator may be used to actively dilate tissue openings, cavities, flaps, etc. such as the fossa ovalis or the coronary sinus."

Ochsner Clinic Foundation

Patent Issued for Fusion Proteins of Collagen-Binding Domain and Parathyroid Hormone (USPTO 9528099)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- According to news reporting originating from Alexandria, Virginia, by NewsRx journalists, a patent by the inventors Gensure, Robert C. (New York, NY); Sakon, Joshua (Fayetteville, AR); Matsushita, Osamu (Okayama, JP); Ponnapakkam, Tulasi (New York, NY), filed on June 18, 2015, was published online on December 27, 2016. The assignee for this patent, patent number 9528099, is Ochsner Clinic Foundation (N/A).

Reporters obtained the following quote from the background information supplied by the inventors: "Osteoporosis is a bone disease characterized by thinning of bone tissue and loss of bone density over time. It is widely prevalent in the elderly. The National Osteoporosis Foundation estimates that by 2020 nearly 14 million Americans will suffer from osteoporosis. An additional 18 million may have low bone mass, or osteopenia. Osteoporosis can occur either because the body fails to make enough new bone or reabsorbs too much old bone, or both.

"Osteoporosis often progresses painlessly until a bone breaks. Any bone can be affected, but one of principal concern is the hip. A hip fracture impairs a person's ability to walk and causes prolonged and sometimes permanent disability.

"Osteoporosis can be treated with anabolic therapies or antiresorptive therapies. Anabolic therapies build new bone. But antiresorptive therapies do not. Instead they slow the resorption of existing bone. A major factor in the control of bone remodeling is parathyroid hormone (PTH). PTH and its analogs are the only class of anabolic therapeutics with proven clinical efficacy. Teriparatide is an approved therapeutic that is a shortened version of PTH. It consists of the N-terminal 34 amino acid residues of mature PTH (PTH(1-34)). Teriparatide is administered by once daily subcutaneous injection.
"PTH is an 84-amino acid peptide. It is involved in mineral ion homeostasis. Increased PTH mobilizes calcium from bone in response to calcium deficient diets or vitamin D insufficiency. PTH also affects osteoblasts and stromal cells. Although hyperparathyroidism is associated with bone loss, PTH administration causes bone gain. PTH binds to receptors on osteoblasts, specialized bone cells that synthesize bone, and this appears to prolong osteoblast life and increase osteoblast activity, causing bone gain.

"PTH-related peptide (PTHrP) is a 141-amino acid protein that is homologous to PTH over its first 13 amino acids but diverges thereafter (1-3). PTH and PTHrP act through a common PTH/PTHrP receptor.

"New treatments for osteoporosis are needed. Improved methods to deliver PTH, teriparatide, or other PTH/PTHrP receptor agonist agents are needed."

In addition to obtaining background information on this patent, NewsRx editors also obtained the inventors' summary information for this patent: "One embodiment disclosed herein involves compositions or bioactive agents comprising a collagen-binding polypeptide segment linked to a PTH/PTHrP receptor agonist. The inventors have constructed fusion proteins containing residues 1-33 of PTH, an active agonist fragment of PTH, fused to a collagen-binding domain (CBD) of CloH, a collagenase from Clostridium histolyticum. The inventors have found that the fusion protein is more active than PTH(1-34) in promoting bone growth in vivo in mice, even when administered systemically. With local administration to, for instance, a fracture site, the difference in efficacy is expected to be even greater. Peptides that are antagonists of the PTH/PTHrP receptor can also be coupled to a CBD for targeted and enhanced bioactivity.

"Compositions or bioactive agents containing a collagen-binding polypeptide segment coupled to a non-peptidyl agonist or antagonist of the PTH/PTHrP receptor are also presented.

"Collagen is the most abundant protein in mammals. It is the major protein component of bone and cartilage. A CBD-bioactive agent fusion protein thus targets the bioactive agent to collagen, and generally to bone and cartilage. The CBD-PTH fusion proteins have longer half-lives than PTH because of their stable binding to collagen, which tends to remove them from circulation. They can be administered locally, for instance, at a fracture site, and will tend to remain at the site of administration through binding to collagen at or near the site of administration. In support of this longer half-life, a fusion protein containing epidermal growth factor (EGF) with a CBD was shown to have much longer half life than EGF alone (8). Data is also presented in Examples 4 and 5 herein showing that a PTH-CBD fusion protein administered weekly or monthly is as effective or more effective than PTH(1-34) administered daily.

"One embodiment provides a composition comprising: a collagen-binding polypeptide segment linked to a PTH/PTHrP receptor agonist; wherein the collagen-binding polypeptide segment is a bacterial collagen-binding polypeptide segment.

"One embodiment provides a composition comprising: a collagen-binding polypeptide segment linked to a PTH/PTHrP receptor agonist; wherein the collagen-binding polypeptide segment is a segment of a collagenase.

"One embodiment provides a composition comprising: a collagen-binding polypeptide segment linked to a PTH/PTHrP receptor agonist; wherein, over an 8-week period, the increase in bone mineral density of the composition injected with a vehicle intraperitoneally weekly in a mouse relative to the vehicle alone is at least 50% larger than the increase in bone mineral density of an equimolar amount of a composition consisting of the PTH/PTHrP agonist relative to the vehicle alone.
"That is, the bioactive agent (composition) causes an increase in bone mineral density in mice when administered at an appropriate dose in a vehicle, such as an aqueous buffer solution. A control treatment with the vehicle alone may also result in some change in bone mineral density, for example because the mice are juveniles that are still growing or elderly mice whose bone mineral density is otherwise declining. The appropriate way to measure the effect of the bioactive agent is to measure increase in bone mineral density in experimental mice treated with the agent minus increase (or decrease) in bone mineral density in control mice treated with vehicle alone. This increase in bone mineral density with administration of the agent after correction for change in bone mineral density in control mice receiving vehicle alone is at least 50% larger than the increase in bone mineral density in mice treated with an agent containing only the PTH/PTHrP receptor agonist (not coupled to a collagen-binding polypeptide segment), again after correcting for any changes in bone mineral density in control mice treated with vehicle alone. For instance, in FIG. 3 herein, described in Example 4, the vehicle control mice have an increase in bone mineral density during an 8-week treatment period of 5%, mice treated with PTH(1-34) (a PTH/PTHrP agonist) have an increase in BMD of about 7.5%, and mice treated with a PTH-CBD fusion protein containing PTH(1-33) coupled to a collagen-binding domain have an increase in BMD of over 15%. The mice treated with the PTH-CBD fusion protein thus have an increase in BMD after correcting for the change with vehicle alone of over 10% (over 15% minus 5%), and the mice treated with PTH(1-34) have an increase in BMD after correcting for the change with vehicle alone of about 2.5% (about 7.5% minus 5%). Thus, intraperitoneal weekly injection of the fusion protein causes over 300% more (over 4-times as much, over 10% versus about 2.5%) increase in BMD as injection of the PTH(1-34).

"Another embodiment provides a fusion protein comprising: a bacterial collagen-binding polypeptide segment; linked to a PTH/PTHrP receptor agonist polypeptide segment.

"Another embodiment provides a fusion protein comprising: a collagen-binding polypeptide segment of a collagenase; linked to a PTH/PTHrP receptor agonist polypeptide segment.

"Another embodiment provides a fusion protein comprising: a collagen-binding polypeptide segment; linked to a PTH/PTHrP receptor antagonist polypeptide segment.

"Another embodiment provides a composition comprising: a collagen-binding polypeptide segment; linked to a non-peptidyl PTH/PTHrP receptor agonist.

"Another embodiment provides a composition comprising: a collagen-binding polypeptide segment; linked to a non-peptidyl PTH/PTHrP receptor antagonist.

"Another embodiment provides a method of promoting bone growth in a mammal comprising: administering to the mammal a composition comprising: (a) a collagen-binding polypeptide segment; linked to (b) a PTH/PTHrP receptor agonist.

"Another embodiment provides a method of promoting bone growth in a mammal comprising: administering to the mammal a composition comprising (a) a collagen-binding polypeptide segment; linked to (b) a PTH/PTHrP receptor agonist.

"Another embodiment provides a method of promoting hair growth in a mammal comprising: administering to the mammal a composition comprising: (i) a collagen-binding polypeptide segment; linked to (ii) a PTH/PTHrP receptor agonist polypeptide segment.

"Another embodiment provides a method of promoting hair growth in a mammal comprising: administering to the mammal a composition comprising: (i) a collagen-binding polypeptide segment; linked to (ii) a PTH/PTHrP receptor antagonist.

"Another embodiment provides a method of promoting tissue growth around an
implant in a mammal comprising: administering to the mammal a composition comprising (a) a collagen-binding polypeptide segment; linked to (b) a PTH/PTHrP receptor agonist; wherein before, during, or after the step of administering the composition, the mammal receives an implant placed in contact with tissue in the mammal; and wherein the step of administering the composition is effective to promote tissue growth around the implant.

"Another embodiment provides a method of promoting immune reconstitution in a mammal comprising: administering to the mammal a composition comprising: (a) a collagen-binding polypeptide segment; linked to (b) a PTH/PTHrP receptor agonist; wherein before, during, or after the step of administering the composition, the mammal receives an administration of bone marrow stem cells. The composition enhances immune reconstitution by enhancing grafting, multiplication, and/or differentiation of the bone marrow stem cells.

"Another embodiment provides a method of promoting bone marrow stem cell mobilization in a mammal comprising: administering to the mammal a composition comprising: (a) a collagen-binding polypeptide segment; linked to (b) a PTH/PTHrP receptor agonist; wherein administering the composition increases the number of stem cells in circulating blood of the mammal (e.g., 7, 14, or 30 days after administering the fusion protein).

"Another embodiment provides a method of treating or preventing renal osteodystrophy in a mammal comprising: administering to the mammal a composition comprising: (a) a collagen-binding polypeptide segment; linked to (b) a PTH/PTHrP receptor antagonist; wherein the mammal is afflicted with renal osteodystrophy or renal disease and the composition is effective to reduce bone loss in the mammal.

"Another embodiment provides a method of treating or preventing (i.e., reducing incidence of) bone metastasis of cancer in a mammal comprising: administering to the mammal a composition comprising: (a) a collagen-binding polypeptide segment; linked to (b) a PTH/PTHrP receptor antagonist; wherein the composition is administered at a dosage effective to reduce incidence of bone metastasis of cancer or slow the growth of metastatic cancer in bone."

WASHINGTON UNIVERSITY
Patent Issued for Glycoengineered Outer Membrane Vesicles and Use Thereof as Vaccines (USPTO 9526775)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- According to news reporting originating from Alexandria, Virginia, by NewsRx journalists, a patent by the inventors Feldman, Mario (Edmonton, CA); Price, Nancy

"Current vaccines against Gram positive bacteria, like Streptococcus pneumoniae, consist of chemically prepared conjugates comprising capsular polysaccharide chemically coupled to a protein carrier. Gram positive bacteria do not produce OMVs.

"There remains a need for alternative OMV vaccines and OMV vaccines against
Gram positive bacteria.

"This background information is provided for the purpose of making known information believed by the applicant to be of possible relevance to the present invention. No admission is necessarily intended, nor should be construed, that any of the preceding information constitutes prior art against the present invention."

In addition to obtaining background information on this patent, NewsRx editors also obtained the inventors' summary information for this patent: "An object of the present invention is to provide glycoengineered outer membrane vesicles ('geOMV') and methods of manufacture and use thereof. The glycoengineered OMV comprise an OMV from a gram-negative bacteria engineered to produce one or more glycans that are not naturally produced from the gram-negative bacteria. When the one or more heterologous glycans are antigenic, these glycoengineered OMVs can be useful as vaccines. Described herein is a method to generate an immune response using glycoengineered OMV in which diverse carbohydrates, including, for example, O antigens from Gram negative and capsule from Gram positive bacteria, are expressed in a bacterium producing OMV, such as Escherichia coli. In one example, it was possible to exploit the similarities between capsule and O antigen synthesis to generate engineered E. coli cells packing capsule from Gram positive bacteria into OMV, to elicit an IgG immune response to the capsule glycan.

"In accordance with an aspect of the present invention, there is provided a recombinant, gram-negative bacteria comprising heterologous DNA encoding an enzyme or enzymes that produce a heterologous glycan, wherein the recombinant bacteria presents the heterologous glycan on its surface as a component of lipopolysaccharides (LPS) that replaces all or a portion of the naturally-occurring O antigen. The heterologous glycan can be one or more of the following: oligosaccharide from N-glycosylated protein (e.g., Campylobacter); oligosaccharide from O-glycosylated protein (e.g., Acinetobacter baumannii, Neisseria or Pseudomonas); O antigen from a gram-negative bacteria (e.g., Burkholderia pseudomallei); capsular polysaccharide from a gram-positive bacteria (e.g., Staphylococcus aureus or Streptococcus pneumoniae) or from a gram-negative bacteria (e.g., Acinetobacter baumannii, Neisseria or Pseudomonas); synthetic or non-bacterial glycan (e.g., Lewis antigen, a glycan identified as an antigen on cancer cells, a glycan derived from a eukaryotic pathogen, such as a fungus, or a glycan derived from a viral pathogen); or a combination of one or more of the above.

"In accordance with another aspect of the invention, there is provided an outer membrane vesicle obtained from recombinant, gram-negative bacteria comprising heterologous DNA encoding an enzyme or enzymes that produce a heterologous glycan, wherein the recombinant bacteria presents the heterologous glycan on its surface as a component of lipopolysaccharides (LPS) that replaces all or a portion of the naturally-occurring O antigen, wherein the outer membrane vesicle expresses the heterologous glycan on its surface.

"In accordance with another aspect of the invention, there is provided an immunogenic composition comprising outer membrane vesicles as described herein, that are obtained from recombinant, gram-negative bacteria comprising heterologous DNA encoding an enzyme or enzymes that produce a heterologous glycan, wherein the recombinant bacteria presents the heterologous glycan on its surface as a component of lipopolysaccharides (LPS) that replaces all or a portion of the naturally-occurring O antigen, wherein the outer membrane vesicle expresses the heterologous glycan on its surface.

"In accordance with another aspect of the invention, there is provided a vaccine comprising outer membrane vesicles as described herein, that are obtained from recombinant, gram-negative bacteria comprising heterologous DNA encoding an enzyme or enzymes that
produce a heterologous glycan, wherein the recombinant bacteria presents the heterologous glycan on its surface as a component of lipopolysaccharides (LPS) that replaces all or a portion of the naturally-occurring O antigen, wherein the outer membrane vesicle expresses the heterologous glycan on its surface.

"In accordance with another aspect of the invention, there is provided a use of an immunogenic composition or vaccine, as described herein, to inoculate a subject against a pathogenic bacteria, wherein the heterologous glycan is derived from the pathogenic bacteria.

"In accordance with another aspect of the invention, there is provided a method of raising an immune response in a mammal comprising administering to the mammal glycoengineered outer membrane vesicles, optionally in an immunogenic composition or a vaccine as described herein."

For more information, see this patent: Feldman, Mario; Price, Nancy; Garcia-Quintanilla, Fatima; Ielmini, Maria Veronica. Glycoengineered Outer Membrane Vesicles and Use Thereof as Vaccines. U.S. Patent Number 9526775, filed April 26, 2013, and published online on December 27, 2016. PHARMED ARTIS GmbH

Patent Issued for Granzyme B Protease Variants (USPTO 9528101)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A patent by the inventors Barth, Stefan (Aachen, DE); Schiffer, Sonja (Juchen, DE); Hehmann-Titt, Grit (Aachen, DE), filed on September 21, 2012, was published online on December 27, 2016, according to news reporting originating from Alexandria, Virginia, by NewsRx correspondents.

Patent number 9528101 is assigned to PHARMED ARTIS GmbH (Aachen, DE).

The following quote was obtained by the news editors from the background information supplied by the inventors: "In the treatment of tumors, autoimmune diseases, allergies and tissue rejection reactions, it is a disadvantage that the currently available medicaments, such as chemotherapeutic agents, corticosteroids and immunosuppressive agents, have a potential of side effects which is sometimes considerable, due to their relative non-specificity. It has been attempted to moderate this by various therapeutical concepts. Especially the use of immunotherapeutic agents is an approach, which resulted in an increase of the specificity of medicaments, especially in tumor treatment.

"If the immunotherapeutic agent is an immunotoxin, then a monoclonal antibody (moAb) or an antibody fragment, which has a kinetic affinity for surface markers of tumor cells, is coupled with a cytotoxic reagent. If the immunotherapeutic agent is an anti-immunoconjugate for the treatment of autoimmune diseases, tissue rejection reactions or allergies, a structure relevant to pathogenesis or a fragment thereof is coupled to a toxin component. It has been
found that immunotoxins can be characterized by a high immunogenicity in clinical use. This causes the formation of neutralizing antibodies in the patient, which inactivate the immunotoxin. Generally, a repeated and/or continuous administration of the therapeutic agents is unavoidable for long-term curative effects. This is particularly clear in the suppression of tissue rejection reactions after transplantsations, or in the treatment of autoimmune diseases, due to the partly demonstrated genetically caused predisposition to a pathogenic autoimmune reaction.

"The peptidic cell poisons which have been mostly used to date and are thus best characterized are the bacterial toxins diphtheria toxin (DT) (Beaumelle, B. et al. 1992; Chaudhary, V. et al. 1990; Kuzel, T. M. et al. 1993; LeMaistre, C. et al. 1998), Pseudomonas exotoxin A (PE) (Fitz Gerald, D. J. et al. 1988; Pai, L. H. and Pastan, I. 1998), and the plant-derived ricin-A (Engert, A. et al. 1997; Matthey, B. et al. 2000; O'Hare, M. et al. 1990; Schnell, R. et al. 2000; Thorpe, P. E. et al. 1988; Youle, R. J. and Neville, D. M. J. 1980). The mechanism of cytotoxic activity is the same in all of these toxins despite of their different evolutionary backgrounds. The catalytic domain inhibits protein biosynthesis by a modification of the elongation factor EF-2, which is important to translation, or of the ribosomes directly, so that EF-2 can no longer bind (Endo, Y. et al. 1987; Iglewski, B. H. and Kabat, D. 1975).

"In most of the constructs employed to date, the systemic application of immunotoxins results in more or less strong side effects. In addition to the 'vascular leak' syndrome (Baluna, R. and Vitetta, E. S. 1997; Schnell, R. et al. 1998; Vitetta, E. S. 2000), thrombocytopenia, hemolysis, renal insufficiency and sickness occur, depending on the construct employed and the applied dosage. Dose-dependent and reversible liver damage could also be observed (Battelli, M. G. et al. 1996; Grossbard, M. L. et al. 1993; Harkonen, S. et al. 1987). In addition to the documented side effects, the immunogenicity of the constructs employed to be observed in the use of the immunoconjugates or immunotoxins is the key problem of immunotherapy (Khazaeli, M. B. et al. 1994). This applies, in particular, to the humoral defense against the catalytic domains employed, such as ricin (HARA) (Grossbard, M. L. et al. 1998), PE (Kreitman, R. J. et al. 2000), or DT (LeMaistre, E. F. et al. 1992).

Theoretically, all non-human structures can provoke an immune response. Thus, the repeated administration of immunotoxins and immunoconjugates is subject to limitations. A logical consequence of these problems is the development of human immunotoxins, now named human cytolytic fusion proteins (Rybak, S. et al. 1992).

"WO 01/80880 A1 discloses the use of granzyme B as a human immunoprotease. The cytotoxic lymphocyte serine proteinase granzyme B induces apoptosis of abnormal cells by cleaving intracellular proteins at sites similar to those cleaved by caspases. However, granzyme B has a number of efficient natural inhibitors that prevent granzyme B-mediated apoptosis in certain cell types.

"Therefore the availability of a human serine protease with improved apoptotic activity and reduced sensitivity towards activity-inhibiting substances would be highly advantageous."

In addition to the background information obtained for this patent, NewsRX journalists also obtained the inventors' summary information for this patent: 'In a first aspect, embodiments of the disclosure provide polypeptides comprising a serine protease variant of wildtype human granzyme B, having a modification at one or more positions and showing increased apoptotic activity compared to wildtype granzyme B and reduced sensitivity to activity-inhibiting substances.

"In a further aspect, embodiments of this disclosure relate to polypeptides comprising a serine protease variant of wildtype human granzyme B as shown in SEQ ID NO: 1, having a
modification at one or more positions selected from the group of positions that correspond structurally or by amino acid sequence homology to the positions 28 and/or 201, or variants, modified forms, homologs, fusion proteins, functional equivalents or functional fragments thereof, wherein said polypeptide having a greater apoptotic activity compared to wildtype granzyme B and reduced sensitivity to activity-inhibiting substances.

"In a further aspect, embodiments of this disclosure relate to polypeptides comprising a serine protease having at least 90% identity to amino acids 1-227 of SEQ ID NO: 1, and which, as compared to amino acids 1-227 of SEQ ID NO: 1, comprises at least one modification at one or more positions corresponding to position 28 and/or 201, or a modified form thereof, wherein said polypeptides having a greater apoptotic activity compared to wildtype granzyme B and reduced sensitivity to activity-inhibiting substances.

"In still another aspect, embodiments of this disclosure provide nucleic acids encoding polypeptides variants with serine protease activity as disclosed herein, as well as vectors and host cells comprising such nucleic acids.

"In other aspects, this disclosure relates to compositions comprising polypeptide variants as described herein, wherein the compositions may be useful for, or used in, therapeutical, cosmetic and/or diagnostic applications. In one advantageous embodiment, the composition is used as a therapeutical composition for the treatment of cancer.

"In a further aspect, embodiments of this disclosure relate to methods for producing the polypeptide variants in a host cell by transforming the host cell with a DNA construct, advantageously including a promoter having transcriptional activity in the host cell, cultivating the transformed host cell in a suitable culture medium to allow expression of said protease and producing the protease. The method may also include recovering the produced protease.

"In an advantageous embodiment of this disclosure, the polypeptide having serine protease activity has the nucleic acid sequence of SEQ ID NO: 3, SEQ ID NO: 4 or SEQ ID NO: 5 or variants, modified forms, homologs, fusion proteins, functional equivalents or functional fragments thereof.

"The polypeptides according to present disclosure can be used for preparing a medicament for preventing or treating a disease like allergy, autoimmune reaction, tissue rejection reaction, or chronic inflammation reaction, in particular cancer.

"In a further aspect, the disclosure relates to purified complexes comprising a binding structure and a polypeptide according to present disclosure, medicaments comprising such a complex in combination with a pharmacologically acceptable carrier or diluent and the use of such a complex for treating a malignant disease, an allergy, autoimmune reaction, tissue rejection reaction, or chronic inflammation reaction, in particular cancer.

"Further, embodiments of this disclosure relate generally to the use of the polypeptides, compositions and complexes according to the present disclosure for the induction of cell death, in particular induction of cell death by apoptosis. Advantageously, polypeptides, compositions and complexes of this disclosure may be used for treating cancer.

"Before the disclosure is described in detail, it is to be understood that this disclosure is not limited to the particular component parts of the devices described or process steps of the methods described as such devices and methods may vary. It is also to be understood that the terminology used herein is for purposes of describing particular embodiments only, and is not intended to be limiting. It must be noted that, as used in the specification and the appended claims, the singular forms 'a,' 'an' and 'the' include singular and/or plural referents unless the context clearly dictates otherwise. It is moreover to be understood that, in case parameter ranges are given which are delimited by numeric values, the ranges are deemed to include these limitation values.
"To provide a comprehensive disclosure without unduly lengthening the specification, the applicant hereby incorporates by reference each of the patents and patent applications referenced above, in particular the disclosure of WO 01/80880 A2 and US 2009/0081185 A1."

Development Center for Biotechnology

Patent Issued for Humanized Alpha-Enolase Specific Antibodies and Methods of Uses in Cancer Therapy (USPTO 9527922)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Development Center for Biotechnology (New Taipei, TW) has been issued patent number 9527922, according to news reporting originating out of Alexandria, Virginia, by NewsRx editors.

The patent's inventors are Tsai, Shih-Chong (New Taipei, TW); Yuan, Ta-Tung (New Taipei, TW); Tseng, Shih-Chi (New Taipei, TW); Lai, Jiann-Shiun (New Taipei, TW); Wu, Chia-Cheng (New Taipei, TW); Huang, Chao-Yang (New Taipei, TW); Tsai, Ya-Wei (New Taipei, TW); Lok, Ying-Yung (New Taipei, TW); Wu, Chung-Hsiun (New Taipei, TW); Shih, Neng-Yao (Miaoli County, TW); Liu, Ko-Jiunn (Miaoli County, TW); Chen, Li-Tzong (Miaoli County, TW).

This patent was filed on December 31, 2014 and was published online on December 27, 2016.

From the background information supplied by the inventors, news correspondents obtained the following quote: "Tumors result from aberrant, unrestrained proliferation of a single cell, generating a clone of transformed cells. Cancer is characterized by tumor cells' autonomous growth and ability to metastasize to distant sites.

"Tumor cells may express unique antigens that can be recognized by the immune system. Tumor-associated antigens include, but are not limited to, mutated oncogenes, mutated normal cellular proteins, aberrantly expressed cellular proteins, abnormal cell-surface proteins, and oncogenic viral proteins. The immune system views these tumor-associated antigens as non-self and can produce antibodies to eradicate these foreign antigen-bearing tumor cells, while sparing the healthy cells. Therefore, identification of immunogenic tumor-associated antigens may be used as targets for clinical prognostic or therapeutic applications in cancer treatment.

"Certain malignancies may be identified by pleural effusion, which is excess fluid in
the space between the lung and chest wall. Lung carcinoma, breast carcinoma, and lymphoma cause about 75% of all malignant pleural effusions. Malignant pleural effusion may be enriched with lymphocytic infiltrates and tumor cells. Tumor-associated immune complexes or autoantibodies, such as anti-p53, antinuclear, and anti-\textcopyright-Myc antibodies, have been found in effusion fluids and are associated with poor prognosis. Several lung tumor-associated antigens have also been identified in malignant effusion, including, cytokeratin 19 fragments, neuron-specific enolase (ENO2), squamous cell carcinoma antigen, and soluble HLA-I, etc.

"Alpha-enolase (enolase-1, ENO1) is a multiple functional protein, which was first found as a key enzyme of the glycolysis pathways. Under normal conditions, ENO1 is expressed in the cytosol. However, ENO1 is also found to express on the cell surfaces of many cancer cells as a plasminogen receptor and on activated hematopoietic cells, such as neutrophils, lymphocytes and monocytes. It is known that the up-regulation of plasminogen receptor proteins can induce a cascade response of the urokinase plasminogen activation system (uPAS).

"The urokinase plasminogen activator system (uPAS) consists of the urokinase plasminogen activator (uPA), its cognate receptor (uPAR) and two specific inhibitors, the plasminogen activator inhibitor 1 (PAI-1) and plasminogen activator inhibitor 2 (PAI-2). Urokinase plasminogen activator converts plasminogen proenzyme into an active serine protease, plasmin. Plasmin is involved in a number of tissue remodeling processes, such as basement membrane (BM) and extracellular matrix (ECM) remodeling, which is required in tumor progression and metastasis. In addition, it has been shown that the uPAS may be involved in the neoplastic evolution, affecting tumor angiogenesis, malignant cell proliferation, adhesion and migration, intra-vascularization, and growth at the metastatic site.

"Specifically, activation of plasminogen can result in extracellular matrix degradations, which in turn can lead to increased metastasis of cancer cells and infiltration of immune cells. In other words, ENO1 expression on cancer cell surfaces as a plasminogen receptor can increase invasion activities of the cancer cells. Therefore, ENO1 is a potential target for cancer therapy."

Supplementing the background information on this patent, NewsRx reporters also obtained the inventors' summary information for this patent: "Embodiments of the invention relate to targeted binding agents (e.g., antibodies, or binding fragments thereof) that specifically bind human ENO1, thereby inhibiting ligand (e.g., plasminogen) binding to ENO1. By inhibiting binding of plasminogen to ENO1, targeted binding agents of the invention can inhibit plasminogen activation, leading to reduced degradation of extracellular matrix, which in turn prevents or reduces dissociation of cancer cells from the extracellular matrix. Therefore, targeted binding agents in accordance with embodiments of the invention can be used to inhibit tumor growth and metastasis. Mechanisms by which this can be achieved may include, but are not limited to, inhibition of binding of a ligand (such as plasminogen) to its receptor ENO1, or abrogation of inter-reactions between the receptor ENO1 and its ligands, thereby reducing the effective concentration of ENO1.

"In accordance with one embodiment of the invention, a targeted binding agent is a humanized antibody that can bind to human ENO1 to prevent its ligands (e.g., plasminogen) from binding to ENO1. Preventing binding of plasminogen to the receptor can prevent plasminogen activation. This results in the inhibition of the urokinase plasminogen activation system (uPAS) in the extracellular matrix of cancer cells.

"In accordance with some embodiments of the invention, the humanized antibody may bind ENO1 with high affinities, such as with a K.sub.d of less than 0.3 nM. Such tight binding agents can inhibit ENO1 with high efficiencies.

"In accordance with some embodiments of the invention, a targeted binding agent is
an humanized antibody that can bind to human ENO1 and inhibit induced plasmin activity on cancer cells with high efficiencies, such as 40%, 50%, 60%, 70%, 80%, 90%, or 100% inhibition. The inhibition assays may be performed by inducing ENO1 expression (hence, plasminogen activation) in a cancer cell (such as U937 human lymphoma cells) by treatment with an inducer, such as lipopolysaccharide (LPS) (e.g., 10 microgram/mL, for 5 hours). Inhibition of such induced plasmin activity may be assayed with an antibody at a suitable concentration. Using an antibody of the invention, such inhibition may be detected at antibody concentrations as low as 20 microgram/ml or less.

"In accordance with some embodiments of the invention, a targeted binding agent is an antibody that can bind to human ENO1. Such an antibody may be used to inhibit the invasion activity of a cancer cell. For example, antibodies of the invention can inhibit greater than 40%, 50%, 60%, or 70% of the invasion activity of U937 human lymphoma cells at antibody concentrations as low as 50 microgram/ml or less.

"In accordance with some embodiments of the invention, a targeted binding agent is an antibody that can bind to human ENO1 to inhibit extracellular matrix degradation, thereby inhibiting cancer cell dissociation from the extracellular matrix. For example, an antibody of the invention can inhibit greater than 40%, 50%, or 60% of plasminogen mediated dissociation of CL1-5 cells from collagen or fibronectin at antibody concentrations as low as 50 microgram/ml or less.

"In accordance with some embodiments of the invention, a targeted binding agent (i.e. a humanized antibody) may comprise a heavy chain amino acid sequence of SEQ ID NO: 1, 10 or 11.

"In accordance with some embodiments of the invention, a targeted binding agent (i.e. a humanized antibody) may comprise a light chain variable region amino acid sequence of SEQ ID NO: 2 or 9.

"In accordance with some embodiments of the invention, a targeted binding agent (i.e. an antibody) may comprise a heavy chain amino acid sequence having a complementarity determining region (CDR) comprising one of the CDR sequences included in sequences 1, 10 or 11. It is noted that those of ordinary skill in the art can readily accomplish CDR determinations. See for example, Kabat et al., 'Sequences of Proteins of Immunological Interest,' Fifth Edition, NIH Publication 91-3242, Bethesda Md. (1991), vols. 1-3.

"In accordance with some embodiments of the invention, a targeted binding agent (i.e. an antibody) may comprise a light chain amino acid sequence having a complementarity determining region (CDR) comprising one of the CDR sequences included in sequence 2 or 9 (FIG. 6B).

"In accordance with some embodiments of the invention, a targeted binding agent is a humanized antibody, or a binding fragment thereof, wherein the antibody may be a monoclonal antibody.

"In accordance with some embodiments of the invention, a humanized antibody that can bind human ENO1 protein comprises a light chain amino acid sequence comprising any one of LCDR1, LCDR2 or LCDR3 sequences included in SEQ ID NO: 9 (FIG. 6B).

"In accordance with some embodiments of the invention, a humanized antibody that can bind human ENO1 protein comprises a light chain amino acid sequence comprising any two of LCDR1, LCDR2 or LCDR3 sequence included in sequence 2 or 9 (that is, LCDR1 and LCDR2, LCDR1 and LCDR3 or LCDR2 and LCDR3).

"In accordance with some embodiments of the invention, a humanized antibody that can bind human ENO1 protein comprises a light chain amino acid sequences that comprises LCDR1, LCDR2 and LCDR3 sequences included in sequence 2 or 9 (FIG. 6B). In accordance
with certain embodiments of the invention, an antibody may be a humanized antibody or a fully human monoclonal antibody.

"In accordance with some embodiments of the invention, an humanized antibody that can bind human ENO1 protein comprises a heavy chain amino acid sequence comprising any one of HCDR1, HCDR2 or HCDR3 sequence included in sequence 1, 10, or 11 (FIG. 6A and FIG. 6B).

"In accordance with some embodiments of the invention, a humanized antibody that can bind human ENO1 protein comprises a heavy chain amino acid sequence that comprises any two of HCDR1, HCDR2 or HCDR3 sequence included in a sequence 1, 10, or 11 (FIG. 6A and FIG. 6B). (that is, HCDR1 and HCDR2, HCDR1 and HCDR3 or HCDR2 and HCDR3).

"In accordance with some embodiments of the invention, a humanized antibody that can bind human ENO1 protein comprises a heavy chain amino acid sequence that comprises HCDR1, HCDR2 and HCDR3 sequences included in sequence 1, 10 or 11 (FIG. 6A and FIG. 6B).

"In accordance with some embodiments of the invention, a humanized antibody that can bind human ENO1 protein comprises a light chain amino acid sequence having a CDR comprising one of the CDR sequences included in sequence 2 or 9 (FIG. 6B). In accordance with some embodiments of the invention, said targeted binding agent comprises a heavy chain amino acid sequence having at least one of the CDR sequences included in sequence 1, 10, or 11, and a light chain amino acid sequence having at least one of the CDR sequences included in sequence 2 or 9.

"In accordance with some embodiments of the invention, a targeted binding agent (i.e. an antibody) can compete for binding of plasminogen to human ENO1 protein. In accordance with some embodiments of the invention, said targeted binding agent comprises a heavy chain amino acid sequence having at least one of the CDR sequences included in sequence 1, 10, or 11, and a light chain amino acid sequence having at least one of the CDR sequences included in sequence 2 or 9.

"Some embodiments of the invention relate to methods for assaying the level of human ENO1 protein in a patient or a patient sample. A method of the invention comprises contacting a humanized anti-ENO1 antibody with a biological sample from a patient, and detecting the level of binding between said antibody and human ENO1 protein in said sample. In more specific embodiments, the biological sample is blood or plasma.

"Other embodiments of the invention relate to compositions comprising a targeted binding agent, which may include a humanized antibody or a functional fragment thereof, and a pharmaceutically acceptable carrier.

"Still further embodiments of the invention relate to methods for effectively treating a subject (e.g., human or animal) suffering from an ENO1 disease or disorder. The method may include selecting a subject in need of a treatment for a neoplastic or non-neoplastic disease, and administering to the subject a therapeutically effective dose of an antibody (which may be a humanized or a fully human monoclonal antibody) that specifically binds to ENO1 protein.

"The humanized antibody of the invention can be used to treat a human ENO1 protein-related disease or disorder. A human ENO1 protein related disease or disorder may be any condition arising from aberrant activation or expression of human ENO1 protein. Examples of such diseases include where human ENO1 protein aberrantly interacts with its ligands, thereby altering cell-adhesion or cell signaling properties. This alteration in cell adhesion or cell signaling properties can result in neoplastic diseases or some immune diseases.
"For example, a human ENO1 protein-related disease may be a neoplastic disease, such as lung, breast, pancreas, liver, colorectal, and prostate cancers.

"Additional embodiments of the invention relate to methods for inhibiting ENO1-induced cell dissociation from extracellular matrix of cancers in a subject. These methods may include selecting a subject (e.g., a human or an animal) in need of treatment for ENO1-induced cell dissociation, and administering to said subject a therapeutically effective dose of an antibody, wherein said antibody specifically binds to ENO1. The antibody is a humanized or fully human monoclonal antibody.

"Further embodiments of the invention relate to the uses of a humanized antibody in the preparation of a medicament for the treatment of an ENO1-related disease or disorder in a subject (e.g., a human or an animal), wherein said antibody specifically binds to ENO1. The antibody is a humanized or fully human monoclonal antibody.

"In accordance with some embodiments of the invention, the targeted binding agents described herein can be used for the preparation of a medicament for the treatment of ENO1 protein-induced cell dissociation from extracellular matrix in an animal, wherein said antibody specifically binds to ENO1. The antibody is a humanized or fully human monoclonal antibody.

"Some embodiments of the invention described herein relate to monoclonal antibodies that bind human ENO1 and affect human ENO1 functions. Other embodiments of the invention relate to anti ENO1 antibody preparations with desirable properties for therapy applications. Such properties may include a high binding affinity for ENO1, the ability to neutralize ENO1 activity in vitro and in vivo, and the ability to inhibit ENO1 induced cell dissociation, growth and metastasis of tumors.

"In some embodiments, the invention relates to a humanized antibody that can bind to human ENO1 with very high affinity (i.e., low K.sub.d). For example a humanized antibody that is capable of binding ENO1 with a K.sub.d less than about 10.sup.-5, 10.sup.-6, 10.sup.-7, 10.sup.-8, 10.sup.-9, 10.sup.-10 or about 10.sup.-11 M, or any range or value there between. Affinity and/or avidity measurements can be performed using ELISA and/or BIACORE, as described herein or according to techniques known in the art.

"It will be appreciated that embodiments of the invention are not limited to any particular form of an antibody or method of generation or production. For example, the anti-ENO1 antibody may be a full-length antibody (e.g., having an intact human Fe region) or an antibody fragment (e.g., a Fab, Fab' or F(ab') sub.2, FV or Dab (Dabs are the smallest functional binding units of human antibodies). In addition, the antibody may be manufactured from a recombinantly produced cell that has been transformed or transfected with a gene or genes encoding the humanized antibody.

"Other embodiments of the invention relate to isolated nucleic acid molecules encoding any of the humanized antibodies described herein, vectors having isolated nucleic acid molecules encoding a humanized anti-ENO1 antibody or a host cell transformed with any of such nucleic acid molecules.

"In addition, some embodiments of the invention relate to a method for producing a humanized anti-ENO1 antibody by culturing host cells under conditions wherein a nucleic acid molecule is expressed to produce the antibody, followed by recovering the antibody. It should be realized that embodiments of the invention may also include any nucleic acid molecule which encodes a humanized antibody or fragment of a humanized antibody of the invention including nucleic acid sequences optimized for increasing yields of antibodies or fragments thereof when transfected into host cells for antibody production.

"Other embodiments relate to the generation and identification of isolated humanized antibodies that can bind specifically to human ENO1. Inhibition of the biological activity of
ENO1 can be effected by these antibodies to prevent ENO1 induced cell dissociation, invasion and other desired effects of cancers.

"Other embodiments of the invention relate to pharmaceutical compositions having an effective amount of a humanized anti-ENO1 antibody. The composition may further comprise a pharmaceutically acceptable carrier or diluent. In yet other embodiments, the anti-ENO1 antibody, or a fragment thereof, is conjugated to a therapeutic agent. The therapeutic agent can be, for example, a toxin or a radioisotope.

"Yet other embodiments of the invention relate to methods for treating diseases or conditions associated with the expression of ENO1 in a patient. The methods may include administering to a patient an effective amount of a humanized anti-ENO1 antibody. The humanized anti-ENO1 antibody can be administered alone, or can be administered in combination with additional antibodies or chemotherapeutic drug or radiation therapy. For example, a monoclonal, oligoclonal or polyclonal mixture of ENO1 antibody that block cell dissociation can be administered in combination with a drug shown to inhibit tumor cell proliferation directly. The method can be performed in vivo and the patient is preferably a human patient. In a preferred embodiment, the method concerns the treatment of an ENO1-related disease or disorder including, but not limited to, neoplastic diseases, such as lung, breast, pancreas, liver, colorectal, prostate cancers and or solid tumors.

"Some embodiments of the invention relate to a method for monitoring cancer development. The method may comprise determining the abundance of alpha-enolase proteins (ENO1) in a sample (e.g., cancer cells), wherein an increased level of ENO1 correlates with cancer severity. In accordance with embodiments of the invention, the abundance may be determined by measuring binding of an ENO1 specific antibody to the ENO1 proteins.

"Some embodiments of the invention relate to a method for detecting cancer. Such a method may comprise determining the abundance of ENO1-specific antibodies in serum samples, wherein a low level of ENO1-specific antibodies indicates the presence of a malignant tumor."

DANA-FARBER CANCER INSTITUTE, INC.

Patent Issued for Humanized Monoclonal Antibodies and Methods of Use (USPTO 9527924)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A patent by the inventors Marasco, Wayne A. (Wellesley, MA); Sui, Jianhua (Stoneham, MA); Avnir, Yuval (Boston, MA), filed on June 2, 2011, was published online on December 27, 2016, according to news reporting originating from Alexandria, Virginia, by NewsRx correspondents.

Patent number 9527924 is assigned to DANA-FARBER CANCER INSTITUTE, INC. (Boston, MA).

The following quote was obtained by the news editors from the background information supplied by the inventors: "An influenza pandemic represents one of the greatest acute infectious threats to human health. The 1918-1919 influenza pandemic caused an estimated 500,000 deaths in the United States, making it the most fatal event in all of US history. The spread of highly pathogenic avian influenza (HPAI) H5N1 influenza across Asia and now to the Middle East and northern Africa creates a substantial risk for a new pandemic to arise.

"Natural variation as well as escape mutants suggests that continued evolution of the virus should impact the decision on which strain(s) should be used for passive and active immunization. Although a number of important epitope mapping and neutralization escape studies have been reported new neutralizing antibodies and related structural studies are needed to develop immunization strategies to develop a ‘universal vaccine’ against a broad range of Group 1 influenza viruses. The challenges to developing a protective vaccine against Group 1 influenza are formidable and new approaches are needed to prevent and treat human infection by an ever changing enemy. There is a need to rapidly develop therapeutic strategies to elicit protective host's immunity, both passively and actively."

In addition to the background information obtained for this patent, NewsRx journalists also obtained the inventors' summary information for this patent: "The invention is based upon the discovery of monoclonal antibodies which bind the human immunoglobulin heavy chain variable region germline gene VH1-69. The monoclonal antibody is fully human. In various aspects, the monoclonal antibody is a bivalent antibody, a monovalent antibody, a single chain antibody or fragment thereof. Exemplary monoclonal antibodies include a monoclonal antibody that binds to the same epitope as murine monoclonal antibody G6.

"The monoclonal antibodies of the invention can have a binding affinity that is 1 nM or less.

"The monoclonal antibody has a heavy chain variable amino acid sequence containing SEQ ID NOS: 2 or 12, and/or a light chain variable amino acid sequence containing SEQ ID NO: 4. The monoclonal antibody has a heavy chain variable nucleic acid sequence containing SEQ ID NOS: 1 or 11, and/or a light chain variable nucleic acid sequence containing SEQ ID NO: 3.

"Also provided by the invention is a monoclonal human immunoglobulin heavy chain variable region germline gene VH1-69 antibody or fragment thereof, where the antibody has a CDRH1: GYTFTSYW (SEQ ID NO: 5); CDRH2: VSPGNSDT (SEQ ID NO: 6); and CDRH3: TRSRYGNALDY (SEQ ID NO: 7) and a CDRL1: QGISSNIWV (SEQ ID NO: 8); CDRL2: HGT (SEQ ID NO: 9); and CDRL3: VQYSEQFPPT (SEQ ID NO: 10).
"In some aspects the antibody according to the invention is covalently linked to an antigen. The antibody is preferably a single chain antibody and the antigen is the stem region of the hemagglutinin (HA) protein of an influenza virus.

"Also included in the invention are methods of augmenting the immune response of a subject to an antigen by administering to the subject an anti-immunoglobulin variable region germline gene idiootype antibody and an immunogen capable of inducing an immune reaction to the antigen. In some aspects the antibody is covalently linked to the antigen. The germline gene encodes for a light chain polypeptide or a heavy chain polypeptide. Preferably, the variable region germline gene is VH1-69. The antigen is a virus, a bacterium, or a fungus. For example the virus is an influenza virus. Preferably, the immunogen is the hemagglutinin (HA) protein of an influenza virus or fragment thereof. Most preferably, the immunogen contains the stem region of the hemagglutinin (HA) protein of an influenza virus. The antibody can be administered prior to, concurrently with, or subsequent to the administration of the immunogen.

"Unless otherwise defined, all technical and scientific terms used herein have the same meaning as commonly understood by one of ordinary skill in the art to which this invention belongs. Although methods and materials similar or equivalent to those described herein can be used in the practice or testing of the present invention, suitable methods and materials are described below. All publications, patent applications, patents, and other references mentioned herein are incorporated by reference in their entirety. In case of conflict, the present specification, including definitions, will control. In addition, the materials, methods, and examples are illustrative only and not intended to be limiting.

"Other features and advantages of the invention will be apparent from the following detailed description and claims."

Keywords for this news article include: Antibodies, Therapy, Genetics, Vaccines, Influenza, Pandemics, Immunology, Epidemiology, Immunization, Blood Proteins, Immunoproteins, Immunoglobulins, Serum Globulins, Biological Products, DANA-FARBER CANCER INSTITUTE INC.

LAZURE SCIENTIFIC, INC.
Patent Issued for Immune Mediated Cancer Cell Destruction, Systems and Methods (USPTO 9526911)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A patent by the inventors Azure, Larry (La Conner, WA); Hill, Charles E. (Issaquah, WA); Azure, Andrew L. (Mount Vernon, WA); Ponce, Rafael (Seattle, WA); Kunz, Lawrence L. (Greenbank, WA), filed on April 27, 2011, was published online on December 27, 2016, according to news reporting originating from Alexandria, Virginia, by NewsRx correspondents.

Patent number 9526911 is assigned to LAZURE SCIENTIFIC, INC. (Issaquah,
The following quote was obtained by the news editors from the background information supplied by the inventors: "The present invention relates generally to electric field delivery to a tissue of a patient. More particularly, the present invention provides systems and methods for delivering electric fields to a target tissue of a patient for destruction of cancerous cells and eliciting or induction of a specific anti-cancerous cell immune response in the patient.

"The immune system is the body's natural defense against infection and disease, destroying foreign elements such as harmful bacteria and viruses that enter the body. In order for the immune system to provide effective defense against disease, it has to recognize and label agents that are 'foreign' and distinguish foreign infection from the body's own non-harmful cells and components. Once this happens, cells in the immune system can function to eliminate the foreign agents.

"Another important role of the immune system is to identify and eliminate tumors. The transformed cells of tumors include proteins or antigens that are not found on normal cells. To the immune system, these antigens appear foreign, and their presence causes immune cells to attack the transformed tumor cells. The antigens produced by tumors can have several sources, and may include those derived from a foreign infecting agent, such as a virus, as well as the body's own proteins that have been mutated or altered, or proteins that occur at low levels in normal cells but reach high levels in tumor cells.

"One primary response of the immune system to tumors is to destroy the abnormal cells using so called natural killer T cells, sometimes with the assistance of other immune cells, such as helper T cells. Tumor antigens may be processed and presented by immune cells in a similar way to viral or bacterial antigens. This allows immune cells such as killer T cells to recognize the tumor cell as abnormal. In addition, in some instances antibodies are generated against tumor cells allowing for their destruction by the complement system.

"While the immune system represents a powerful and vital defense against cancer, in some cases, tumors evade the immune system and go on to become cancers. Thus, there is great interest in cancer immunotherapy treatments and techniques that utilize or stimulate the body's own immune system to better combat and eradicate cancerous cells in the body. Cancer immunotherapy aims to teach the body's own natural defenses to identify cancer cells correctly and then kill them. There are different types of cancer immunotherapy, including cancer vaccines and a treatment called Antigen-Specific Cancer Immunotherapeutics (ASCI).

"While cancer immunotherapy holds tremendous promise, to date very few effective treatments have been developed. Thus, there is continued interest in techniques and treatments that can stimulate a patient's immune system to better combat cancerous cell growth."

In addition to the background information obtained for this patent, NewsRx journalists also obtained the inventors' summary information for this patent: "Systems and methods are provided for delivering electric fields to a target tissue of a patient for destruction of cancerous cells so as to elicit or induce a specific anti-cancerous cell immune response in the patient. Methods include establishing an electrical current flow through a volume of the target tissue so as to preferentially destroy cancerous cells in the volume.

"Thus, in one aspect, the present invention includes systems and related methods for delivering electric fields to a target tissue of a patient for destruction of cancerous cells, including establishing an electrical current flow through a volume of the target tissue so as to preferentially destroy cancerous cells in the volume and induce a specific host anti-cancerous cell immune response. The electrical current flow can be selected such that thermal based protein coagulation and denaturation in the cancerous cells or tissue is minimized or substantially avoided. Administering an immunostimulatory agent or adjuvant can further be
accomplished.

"In another aspect, the present invention further includes methods including identifying a first target tissue site and a second target tissue site; eliciting destruction of cancerous cells of the first target tissue site comprising establishing an electrical current flow through a volume of the second target tissue so as to preferentially destroy cancerous cells in the volume and induce a specific host anti-cancerous cell immune response so as to control growth of cancerous cells at a location remote from the second target tissue that have not directly received electrical current flow. In some instances, cancerous cells will have been seeded at the second target tissue site.

"The present invention further includes systems and methods for delivering electric fields to a target tissue of a patient for destruction of cancerous cells, including identifying a first target tissue site and a second target tissue site; eliciting destruction of cancerous cells of the first target tissue site including establishing an electrical current flow through a volume of the second target tissue so as to preferentially destroy cancerous cells in the volume; removing tissue or fluid from the second target tissue following electrical current application; delivering to the first target tissue site the tissue or fluid removed from the second target tissue, so as to reduce growth of cancerous cells at a location remote from the second target tissue that have not directly received electrical current flow.

"For a fuller understanding of the nature and advantages of the present invention, reference should be made to the ensuing detailed description and accompanying drawings. Other aspects, objects and advantages of the invention will be apparent from the drawings and detailed description that follows."

Keywords for this news article include: Antigens, Cancer, Tumors, Genetics, Oncology, Immunology, Immunotherapy, Biological Factors, Drugs and Therapies, LAZURE SCIENTIFIC INC., Hemic and Immune Systems.

Teva Pharmaceuticals Industries Ltd.

Patent Issued for Inhalers and Housing Caps for Inhalers (USPTO 9526858)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- According to news reporting originating from Alexandria, Virginia, by NewsRx journalists, a patent by the inventor Zuyderhoudt, Krijn Franciscus Marie (Leiden, NL), filed on November 30, 2011, was published online on December 27, 2016.

The assignee for this patent, patent number 9526858, is Teva Pharmaceuticals Industries Ltd. (Petach Tivka, IL).

Reporters obtained the following quote from the background information supplied by the inventors: "A known inhaler for inhalation into the airway of a user has a housing at least
partially defining a flow passageway extending through the inhaler from an air inlet to an outlet. A pressurised metered dose canister may be placed in the housing and, when a user sucks on a mouthpiece of the housing, air may be drawn into the housing between the canister and an inner wall of the housing and may flow along past the canister towards the outlet. The canister includes a valve stem and a metering valve arranged to seat in a valve stem block formed on the housing and a main canister body of the canister may be moved relative to the housing and valve stem so as to operate the metering valve and fire a metered dose of propellant and active drug through the valve stem block and into the flow passageway.

"This type of inhaler often works well, but some users may find it difficult to coordinate an inward breath for inhalation with firing of the canister and, if the canister is fired too early or late relative to an inhalation breath, optimum inhalation may not be achieved.

"In WO 2009/128491, which is incorporated by reference herein, a vinyl bag with holes in it is attached to an inhaler body to provide air flow resistance.

"In WO 98/41252, which is incorporated by reference herein, an inhaler includes an end cap and housing and the end cap is slideable relative to the housing between a configuration in which there are respective minimum and maximum air flows through the housing. The housing has to be specially formed with a rim and a special collar needs to be located between the housing and end cap and a movement of the collar relative to a dispensing container of the device is undesirably required during an initial setting up of the device. It may also be possible for fluff or debris to become lodged but difficult to sense near the air inlets of the device near the collar, potentially allowing inhalation thereof, and the air inlet area is limited by narrow gaps between the collar and housing.

"WO 2008/040062, which is incorporated by reference herein, discloses an inhaler with a cover cap arranged to seal the inhaler so that nothing may enter the inhaler through a housing top in order to exclude mud and dust and for use in wet conditions. The cover cap is flexible to allow operation of the device's canister without allowing mud or dust on the cap to be sucked in and inhaled. However, this requires a complicated arrangement of moving parts elsewhere on the housing in order to provide an air inlet. It is known to provide a breath-actuated inhaler in which the act of inhalation by a user causes a dose to be provided, but this type of device is fairly complicated and expensive."

In addition to obtaining background information on this patent, NewsRx editors also obtained the inventor's summary information for this patent: "The present invention aims to alleviate at least to a certain extent the problems of the prior art.

"According to a first aspect of the invention there is provided a housing cap apparatus for an inhaler, the housing cap having a valve for selectively restricting air flow through an air flow passageway of an inhaler. This is advantageous in that the valve can be used to restrict or prevent the user or patient from inhaling at a sub-optimal time relative to drug delivery and may, in particular prevent the user from inhaling substantially too early.

"Preferably, at least a portion thereof comprising a deformable portion formed of deformable material and including at least one valve, the deformable portion being deformable between a first configuration in which the valve is restricted and a second configuration in which the valve is open for allowing air flow through an air flow passageway of an inhaler. This is advantageous in that the valve can be used to restrict or prevent the user or patient from inhaling at a sub-optimal time relative to drug delivery and may, in particular prevent the user from inhaling substantially too early. Also, an inhaler using such a housing cap is reliable in its timing of dosing and inhalation, is easy to use and a relatively large valve opening may be achieved with little movement or effort. Additionally a smooth surface area can be provided in the region of the valve which is not likely to accumulate fluff or debris in a position from which
it may be inhaled.

"The housing cap may have a head portion at least partly formed of deformable material, the valve comprising at least one sealing aperture which is deformable between a closed configuration and an open configuration. The head portion may be formed at least partly of resiliently deformable material for self-closing the sealing aperture to the closed configuration and self-returning the head portion to a rest configuration thereof.

"The sealing aperture may be located on an inwardly concave surface of the head portion so as to be biased towards firmer sealing thereof in response to attempted negative inhaling pressure applied inside the head portion. Advantageously, therefore, the sealing arrangement cannot easily be opened just by inhaling with greater force. The sealing aperture may comprise an elongate sealing slit.

"The elongate sealing slit may be formed in a sidewall of the head portion.

"The sidewall may be generally at least part-cylindrical or at least part-conical when the sealing slit is in the closed configuration. The sidewall may have a lower generally cylindrical portion and an upper generally conical portion and the elongate sealing slit may extend at least partly along each of the generally cylindrical and generally conical portions.

"The sidewall may have a curved outwardly convex cross section when the sealing slit is closed. This has the advantage that the sidewall releasably collapses outwardly all around a perimeter thereof as the housing cap is deformed to the open configuration.

"The housing cap may include at least one corner and in which at least one said sealing slit is located substantially adjacent and/or aligned extending substantially towards the corner. This configuration has been found to be highly advantageous since it allows substantial opening of the sealing slit in response to little movement of input to the housing cap to open the slit.

"A series of said sealing slits may be arranged around the sidewall. In one example, four said sealing slits and four said corners may be provided. This arrangement is highly effective, enabling easy and wide opening of the slits to enable high air flow rates upon inhalation with little resistance due to pressure drop across the valve during proper inhalation. Between four and twenty said slits may be provided in some embodiments, some embodiments having between eight and fifteen said slits, one example having twelve said slits, another having four slits.

"When the sealing slit is closed, the head portion may have a generally flat top and the sealing slit may be oriented generally parallel to an axis perpendicular to the generally flat top of the head portion. Accordingly, manual pushing of the head portion along the axis perpendicular to the flat top may open the slit/series of slits.

"The generally flat top may be relatively rigid compared to the sidewall. Thus the sidewalls may deform without significant deformation of the flat top. The generally flat top may be: of thicker material than the sidewall, formed of stiffer material than the sidewall (such as being double-shot moulded integrally therewith), or both. Double shot moulding is possible when a stiffer material is used for the top. The extra stiffness of the top prevents undesirable deformation. For example, the centre of the top cannot easily be pushed down to fire the canister without the slits opening properly. The generally flat top may act to spread forces through the slits.

"The generally flat top may include an insert formed of stiffer and/or harder material than material of the sidewall.

"The sidewall may have a Shore A hardness of about 30, or from about 25 to about 35 Shore A. The generally flat top may have a Shore D hardness of about 40 or less, or from
about 35 to about 45 Shore D.

"The generally flat top may have a Shore A hardness of about 85, or from about 75 to about 100 Shore A.

"The generally flat top may incorporate a central concave finger grip. The finger grip may be surrounded by a chamfer. This encourages the user to push with a central force for good even deformation while also allowing enough room for the user's index finger to operate the housing cap comfortably and helps to align the finger.

"The sidewall may be arranged to adopt a deformed bulging configuration (such as an at least part-oblata spheroidal, an at least part-prolate spheroidal or at least part-spherical configuration) when the sealing slit is in the open configuration. With the sidewall cylindrical or conical in the closed configuration, as the head portion is pushed, the sidewall may gradually adopt a generally part-spheroidal configuration and it may transform through a generally part-prolate spheroidal configuration to a generally part-oblata spheroidal configuration or a generally part-spherical configuration as the sealing slit is progressively opened. The head portion may have an engagement portion arranged to engage, move and fire a metered dose canister. Such engagement may be direct or indirect such as via a return spring. The generally flat top may have a lower surface thereof having a downwardly convex central dome surround by a concave annular gutter leading to a downwardly extending cylindrical wall portion. The lower surface may therefore directly mate on top of and engage a metered dose canister with a corresponding mating surface. This advantageously allows a tight fit on the canister, minimising sideways movement if the head portion is pushed sideways, so that apertures/slits cannot be inadvertently deformed and opened without pushing the canister down to fire it.

"The engagement portion may comprise a component, such as an insert, the component having a flange of at least partly circular form for engaging a metered dose canister.

"The housing cap may include a skirt arrangement arranged to sealingly engage a housing of an inhaler. The slit or series of slits may be spaced from the skirt such that once the housing cap is fixed on the housing (of the inhaler), the slits are spaced from the housing such that when they are opened air may accordingly pass through the slits and into the housing. The skirt arrangement may include a stiffening portion, the stiffening portion having greater stiffness and/or hardness (durometer) than a sidewall portion of the housing cap.

"The skirt arrangement may have a shape arranged to fittingly match an end of an inhaler housing in only one relative angular configuration. The shape may have reflection symmetry, such as bilateral symmetry. The shape may have no rotational symmetry.

"The housing cap may be removable from the housing, such as by sliding or the provision of mutually engaging threads which permit a threaded twisting removal action for the housing cap. This may therefore advantageously allow cleaning of the housing cap and the housing of any inhaler to which it is attached.

"The valve may be operably-connected to a top of the cap such that depression of the top of the cap opens the valve from its closed, rest position. Preferably, the top of the cap is shaped to provide a corner aligned, adjacent or otherwise in communication with the valve, to facilitate opening of the valve. Further preferably, a top of the cap comprises an insert providing a corner aligned, adjacent or otherwise in communication with the valve, to facilitate opening of the valve. Most preferably, a corner per valve is provided, preferably four corners one for each of the four valves. This arrangement is highly effective, enabling easy and wide opening of the slits/valves to enable high air flow rates upon inhalation with little resistance due to pressure drop across the valve during proper inhalation. Preferably, the generally flat top includes a central concave finger grip. The finger grip may be surrounded by a chamfer.

"The generally flat top may have a lower surface thereof arranged to mate on top of a
A metered dose canister. The lower surface may have a downwardly convex central dome surrounded by a concave annular gutter leading to a downwardly extending cylindrical wall portion of the generally cylindrical flat top.

"The apparatus may include a skirt arranged to sealingly engage a housing of an inhaler. The cap may be arranged to be connectable to an inhaler housing by provision of mutually engaging threads which permit a threaded twisting removal or connection thereof. A second aspect of the invention provides an inhaler for inhalation into the airway of a user, the inhaler having a housing at least partially defining a flow passageway extending through the inhaler from an air inlet to an outlet, the inhaler including apparatus in accordance with the first aspect of the invention. Preferably, a metered dose canister is located in the housing.

"A third aspect of the present invention provides an inhaler for inhalation into the airway of a user, the inhaler having a housing at least partially defining a flow passageway extending through the inhaler from an air inlet to an outlet, wherein a valve is provided for selectively restricting the flow passageway. This is also advantageous in that the valve can be used to restrict or prevent the user or patient from inhaling at a sub-optimal time relative to drug delivery and may, in particular prevent the user from inhaling substantially too early.

"The inhaler may further comprise a housing cap apparatus in accordance with the first aspect of the invention.

"Preferably, the inhaler having a housing at least partially defining a flow passageway extending through the inhaler from an air inlet to an outlet, the inhaler having a deformable portion formed of deformable material and including at least one valve, the deformable portion being deformable between a first configuration in which the valve is restricted and a second configuration in which the valve is open for allowing air flow through the air flow passageway. This is advantageous in that the valve can be used to restrict or prevent the user or patient from inhaling at a sub-optimal time relative to drug delivery and may, in particular prevent the user from inhaling substantially too early. The deformable portion may comprise at least part of a housing cap, the housing cap being in accordance with the first aspect of the invention. A further aspect of the invention provides an inhaler for inhalation into the airway of a user, the inhaler having a housing at least partially defining a flow passageway extending through the inhaler from an air inlet to an outlet, wherein a valve is provided for selectively restricting the flow passageway. This is also advantageous in that the valve can be used to restrict or prevent the user or patient from inhaling at a sub-optimal time relative to drug delivery and may, in particular prevent the user from inhaling substantially too early.

"The outlet may comprise an aperture in a mouthpiece of the housing. The housing may have a canister-receiving portion arranged to receive a metered dose canister.

"The inhaler may include a metered dose canister arranged to be located in the canister-receiving portion, the canister having a main body which is movable in the canister-receiving portion for firing a metered dose of drug into the flow passageway.

"The canister may have a stem extending from the main body and a metering valve, the main body being pressurised and movable relative to the valve stem for firing the metered dose via the metering valve. Accordingly, a metered dose canister may advantageously be fired at a time when the valve is at a correct moment during or just after the valve for the flow passageway is opened or after the valve begins to open such that good timing and coordination may be achieved.

"The valve may be fully closable for fully preventing air flow along the flow passageway. Accordingly a user may be totally unable to inhale through the device when the valve is fully closed and will be prevented from starting an inhalation breath too long before a dose of drug is provided.
"The valve may be operable in response to a manual operation so as to permit airflow along the flow passageway. For example, the valve may be operable in response to a manual movement by hand of a metered dose canister received in the housing or by an element such as a housing cap or other actuator mounted to the housing and arranged to act upon such a canister. The canister and the valve may be arranged for coordinated opening of the valve and firing of the metered dose in response to a manual operation, the canister being moveable in the housing in response to the manual operation. In this case, the valve may be moveable in the housing in response to the manual operation. This is highly advantageous in that the provision of a drug, such as by way of a metered dose from the canister, may be timed to be at an optimum moment during an inhalation breath.

"The valve may include a sealing ring arranged to selectively form a seal between a metered dose canister and an inner wall of the housing. A metered dose canister may be located in the housing, the canister having a cylindrical surface arranged to selectively seal inside the sealing ring. The canister may have neck portion or other formation of smaller cross-dimension, e.g. diameter, than the cylindrical surface and may be slideable in the housing for placing the neck portion adjacent the sealing ring and spaced inwardly therefrom so as to open the valve. In this way, the valve may advantageously be opened at an optimum moment during movement of the canister so as to provide a dose of drug.

"A ring may be located in the housing and arranged to steady a canister inside the housing. This may therefore provide excellent sealing at the sealing ring and may assist in providing smooth sliding of the canister relative to the sealing ring. The sealing ring may be flexible and may additionally be arranged to deform from a closed configuration to an open configuration in which it permits airflow along the flow passageway. The inhaler may include a housing cap arranged to fit on the housing, at least part of the housing cap being moveable relative to the housing for opening and closing the valve. The housing may have at least one aperture formed in an outer wall thereof and the housing cap may have at least one inlet aperture formed through a wall thereof, the housing cap being moveable relative to the housing to place the apertures in and out of register with one another for opening and closing valve, respectively.

"The housing cap may have a skirt arranged to mate around the housing.

"The housing cap may be removably attachable to the housing.

"Housing caps in accordance with or used in any of the above aspects may advantageously be fitted to an inhaler housing thereby providing a valve for restricting or blocking airflow through the inhaler, such that opening of the valve from a restricted or fully blocking configuration may be coordinated with drug delivery for optimum inhalation. Housing caps with these features may be fitted to a wide range of existing inhaler housing bodies, thereby substantially improving the performance of the same without requiring substantial redesign costs.

"Housing caps in accordance with or used in any of the aspects of the invention may have a head portion formed of deformable material, the head portion incorporating the valve, which is in the form of at least one sealing aperture which is deformable between a closed configuration and an open configuration. The housing cap may be so deformable by pressing downwardly on the head portion. The closed configuration may be a relaxed or rest configuration of the head portion and the open configuration may be a deformed configuration thereof, such that the head portion may advantageously be biased towards and return to the closed configuration from the open configuration automatically. The head portion may be formed of resiliently deformable material for self-closing the aperture to the closed configuration and/or self-returning the head portion to the rest configuration."

Vitae Pharmaceuticals, Inc.

Patent Issued for Inhibitors of Beta-Secretase (USPTO 9526727)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- From Alexandria, Virginia, NewsRx journalists report that a patent by the inventors Bukhtiyarov, Yuri (Boothwyn, PA); Cacatian, Salvacion (Conshohocken, PA); Dillard, Lawrence Wayne (Yardley, PA); Dorner-Ciossek, Cornelia (Ingelheim am Rhein, DE); Fuchs, Klaus (Ingelheim am Rhein, DE); Jia, Lanqi (Horsham, PA); Lala, Deepak S. (Lower Gwynedd, PA); Morales-Ramos, Angel (Blue Bell, PA); Reeves, Jonathan (Ridgefield, CT); Singh, Suresh B. (Kendall Park, NJ); Venkatraman, Shankar (Lansdale, PA); Xu, Zhenrong (Chalfont, PA); Yuan, Jing (Lansdale, PA); Zhao, Yi (Blue Bell, PA); Zheng, Yajun (Hockessin, DE); Rast, Georg (Ingelheim am Rhein, DE), filed on February 4, 2015, was published online on December 27, 2016.

The patent's assignee for patent number 9526727 is Vitae Pharmaceuticals, Inc. (Fort Washington, PA).

News editors obtained the following quote from the background information supplied by the inventors: "beta.-Amyloid (also referred to herein as 'Abeta' or 'A.beta.') deposits and neurofibrillary tangles are two major pathologic characterizations associated with Alzheimer's disease (AD), including the genetically linked early onset familial forms due to mutations in amyloid precursor protein (APP), presenilin 1 and 2, as well as late onset sporadic AD. Clinically, AD is characterized by the loss of memory, cognition, reasoning, judgment, and orientation. Also affected, as the disease progresses, are motor, sensory and linguistic abilities until global impairment of multiple cognitive functions occurs. These cognitive losses take place gradually, but typically lead to severe impairment and eventual death in 4-12 years.

"beta.-Amyloid deposits are predominantly an aggregate of Abeta peptide, which in turn is a product of the proteolysis of APP. More specifically, AP peptide results from the cleavage of APP at the C-terminals by one or more .gamma.-secretases, and at the N-terminus by .beta.-secretase enzyme (BACE1), also known as aspartyl protease and memapsin2, as part of the .beta.-amyloidogenic pathway.

"BACE activity is correlated directly to the generation of A.beta. peptide from APP, and studies increasingly indicate that the inhibition of BACE inhibits the production of A.beta. peptide.

"Amyloidogenic plaques and vascular amyloid angiopathy also characterize the brains of patients with Trisomy 21 (Down Syndrome), Hereditary Cerebral Hemorrhage with Amyloidosis of the Dutch-type (HCHWA-D), and other neurodegenerative disorders. Neurofibrillary tangles also occur in other neurodegenerative disorders including dementia-inducing disorders.

"Recently, Abeta has been reported to be implicated in the development of retinal
ganglion cell (RGC) apoptosis in glaucoma, with evidence of caspase-3-mediated abnormal amyloid precursor protein processing, increased expression of Abeta in RGCs in experimental glaucoma and decreased vitreous A.beta. levels (consistent with retinal A.beta. deposition) in patients with glaucoma. Amyloid deposits have also been associated with macular degeneration in patients suffering from dry age-related macular degeneration (AMD) and in animal models of AMD.

As a supplement to the background information on this patent, NewsRx correspondents also obtained the inventors' summary information for this patent: "The present invention provides compounds that are BACE1 inhibitors and are useful as therapeutic agents in the treatment of a disease or disorder characterized by elevated .beta.-amyloid deposits or .beta.-amyloid levels in a patient. The disclosed BACE1 inhibitors are not only highly potent inhibitors of the BACE1 enzyme (assay 1) but also show: (1) highly potent inhibitory activity in the cellular Abeta assay (assay 2), (2) selectivity against the cardiac hERG channel in a cellular assay (assay 3), and (3) a low propensity to cause phospholipidosis in a cellular phospholipidosis assay (assay 4), as well.

"Thus, the present invention provides compounds which show a combination of high potency as BACE1 inhibitors, high selectivity against the cardiac hERG channel, and low phospholipidosis activity.

"One embodiment of the invention is a compound represented by a structural formula selected from:

```
##STR00001## ##STR00002## ##STR00003## ##STR00004## ##STR00005##
```
or a pharmaceutically acceptable salt of any of the foregoing compounds. The immediately foregoing compounds are referred to herein as 'compounds of the present invention'.

"Another embodiment of the invention is a compound of the present invention or a pharmaceutically acceptable salt thereof for use as a medicament.

"Another embodiment of the invention is a pharmaceutical composition comprising a compound of the present invention or a pharmaceutically acceptable salt thereof in admixture with a pharmaceutically acceptable adjuvant, diluent or carrier.

"Another embodiment of the invention is a compound of the present invention or a pharmaceutically acceptable salt thereof for use in the treatment of a BACE1 mediated disorder or disease in a subject.

"Another embodiment of the invention is the use of a compound of the present invention or a pharmaceutically acceptable salt thereof for the manufacture of a medicament for the treatment of a BACE1 mediated disorder in a subject.

"Another embodiment of the invention is a method of treating a subject with a BACE1 mediated disease or disorder, comprising administering to the subject an effective amount of a compound of the present invention or a pharmaceutically acceptable salt thereof.

"Yet another embodiment of the invention is an intermediate used in the preparation of a compound of the present invention. These intermediates are represented by a structural formula selected from:

```
##STR00006## ##STR00007## ##STR00008## ##STR00009## or a salt of any of the foregoing compounds."

**Patent Issued for Injectable Biodegradable Particles (USPTO 9526804)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- According to news reporting originating from Alexandria, Virginia, by NewsRx journalists, a patent by the inventor O'Gara, John E. (Ashland, MA), filed on July 10, 2012, was published online on December 27, 2016.

The assignee for this patent, patent number 9526804, is Boston Scientific Scimed, Inc. (Maple Grove, MN).

Reporters obtained the following quote from the background information supplied by the inventors: "Many clinical situations benefit from regulation of the vascular, lymphatic or duct systems by restricting the flow of body fluid or secretions. For example, the technique of embolization involves the introduction of particles into the circulation to occlude blood vessels, for example, so as to either arrest or prevent hemorrhaging or to cut off blood flow to a structure or organ. Permanent or temporary occlusion of blood vessels is desirable for managing various diseases and conditions.

"In a typical embolization procedure, local anesthesia is first given over a common artery. The artery is then percutaneously punctured and a catheter is inserted and fluoroscopically guided into the area of interest. An angiogram is then performed by injecting contrast agent through the catheter. An embolic agent is then deposited through the catheter. The embolic agent is chosen, for example, based on the size of the vessel to be occluded, the desired duration of occlusion, and/or the type of disease or condition to be treated, among others factors. A follow-up angiogram is usually performed to determine the specificity and completeness of the arterial occlusion.

"Various polymer-based microspheres are currently employed to embolize blood vessels. These microspheres are usually introduced to the location of the intended embolization through microcatheters. Many commercially available embolic microspheres are composed of polymers. Materials commonly used commercially for this purpose include polyvinyl alcohol (PVA), acetalized PVA (e.g., Contour SE.TM. embolic agent, Boston Scientific, Natick, Mass., USA) and crosslinked acrylic hydrogels (e.g., Embospheres.RTM., Biosphere Medical, Rockland, Mass., USA). Similar microspheres have been used in chemoembolization to increase the residence time of the therapeutic after delivery. In one specific instance, a therapeutic agent (doxorubicin) has been directly added to polyvinyl alcohol hydrogel microspheres such that it can be released locally after delivery (e.g., DC Bead.TM. drug delivery chemoembolization system, Biocompatibles International plc, Farnham, Surrey, UK)."
Other examples of commercially available microspheres include glass microspheres with entrapped radioisotopes (e.g., 90Y), in particular, TheraSpheres.TM., MDS Nordion, Ottawa, Canada and polymer microspheres that contain monomers that are capable of chelating radioisotopes (90Y), in particular, SIR-Spheres.RTM., SIRTex Medical, New South Wales, Australia.

"Currently, the only commercial biodegradable embolic material is GelFoam. Although used clinically, the material has the disadvantage that it is not available in a spherical form, which can lead to problems and variability during delivery through microcatheters. A spherical embolic material that is degradable would thus be attractive since it would have the benefits of the microsphere based materials such as a physician’s familiarity with microsphere handling and delivery as well as a longer and more flexible time period to handle and deliver the embolic material, while also possessing the capability of biodegrading over time in vivo, which is beneficial, for example, because the vasculature of the structure or organ being treated (e.g., tumor, etc.) may be accessed for additional treatments at a later time and/or because of reduced risk of complications or patient objections arising from a permanently implanted material.

"It is also known to use polymer-based microspheres as augmentative materials for aesthetic improvement, including improvement of skin contour. Furthermore, polymer-based microspheres have also been used as augmentative materials in the treatment of various diseases, disorders and conditions, including urinary incontinence, vesicourethral reflux, fecal incontinence, intrinsic sphincter deficiency (ISD) and gastro-esophageal reflux disease, among others. For instance, a common method for treating patients with urinary incontinence is via perirethral or transperineal injection of a bulking agent that contains polymer-based microspheres. In this regard, methods of injecting bulking agents for treatment of urinary incontinence commonly require the placement of a needle at a suitable treatment region, for example, perirethraly or transperineally. The bulking agent is injected into a plurality of locations, assisted by visual aids, causing the urethral lining to coapt. Commercially available bulking agents are typically biostable."

In addition to obtaining background information on this patent, NewsRx editors also obtained the inventor’s summary information for this patent: "In accordance with one aspect of the invention, biodegradable injectable polymeric particles are provided that contain a copolymer that contains a hydroxy-acid-based repeat unit selected from a mono(hydroxy acid) unit and a poly(hydroxy acid) unit, an alkyl-ether-based repeat unit selected from a mono(alkyl ether) unit and a poly(alkyl ether) unit, and an acid-based repeat unit selected from a unit comprising multiple carboxylic acid groups and derivatives thereof.

"Other aspects of the invention pertain to methods of making such particles. Still other aspects of the invention pertain to injectable compositions that comprise such particles and to methods of treatment that employ such injectable compositions.

"These and various additional aspects, embodiments and advantages of the present invention will become immediately apparent to those of ordinary skill in the art upon review of the Detailed Description and any appended claims to follow."

SpineCore, Inc.

**Patent Issued for Intervertebral Disc and Insertion Methods Therefor (USPTO 9526634)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- According to news reporting originating from Alexandria, Virginia, by NewsRx journalists, a patent by the inventors Errico, Joseph P. (Warren, NJ); Dudasik, Michael W. (Nutley, NJ); Errico, Thomas J. (New York, NY); Zubok, Rafail (Midland Park, NJ), filed on April 4, 2016, was published online on December 27, 2016.

The assignee for this patent, patent number 9526634, is SpineCore, Inc. (Allendale, NJ).

Reporters obtained the following quote from the background information supplied by the inventors: "The present invention is directed to a spinal joint replacement implant and more particularly to a cervical intervertebral disc implant having saddle shaped articulating surfaces and to methods of inserting the cervical intervertebral disc implant.

"As is well known to those skilled in the art, the structure of the intervertebral disc disposed between the cervical bones in the human spine comprises a peripheral fibrous shroud (the annulus) which circumscribes a spheroid of flexibly deformable material (the nucleus). The nucleus comprises a hydrophilic, elastomeric cartilaginous substance that cushions and supports the separation between the bones while also permitting articulation of the two vertebral bones relative to one another to the extent such articulation is allowed by the other soft tissue and bony structures surrounding the disc. The additional bony structures that define pathways of motion in various modes include the posterior joints (the facets) and the lateral intervertebral joints (the unco-vertebral joints). Soft tissue components, such as ligaments and tendons, constrain the overall segmental motion as well.

"Traumatic, genetic, and long term wearing phenomena contribute to the degeneration of the nucleus in the human spine. This degeneration of this critical disc material, from the hydrated, elastomeric material that supports the separation and flexibility of the vertebral bones, to a flattened and inflexible state, has profound effects on the mobility (instability and limited ranges of appropriate motion) of the segment, and can cause significant pain to the individual suffering from the condition. Although the specific causes of pain in patients suffering from degenerative disc disease of the cervical spine have not been definitively established, it has been recognized that pain may be the result of neurological implications (nerve fibers being compressed) and/or the subsequent degeneration of the surrounding tissues (the arthritic degeneration of the facet joints) as a result of their being overloaded.

"Traditionally, the treatment of choice for physicians caring for patients who suffer from significant degeneration of the cervical intervertebral disc is to remove some, or all, of the damaged disc. In instances in which a sufficient portion of the intervertebral disc material is removed, or in which much of the necessary spacing between the vertebrae has been lost (significant subsidence), restoration of the intervertebral separation is required.

"Unfortunately, until the advent of spine arthroplasty devices, the only methods known to surgeons to maintain the necessary disc height necessitated the immobilization of the segment. Immobilization is generally achieved by attaching metal plates to the anterior or posterior elements of the cervical spine, and the insertion of some osteoconductive material
(autograft, allograft, or other porous material) between the adjacent vertebrae of the segment. This immobilization and insertion of osteoconductive material has been utilized in pursuit of a fusion of the bones, which is a procedure carried out on tens of thousands of pain suffering patients per year.

"This sacrifice of mobility at the immobilized, or fused, segment, however, is not without consequences. It was traditionally held that the patient's surrounding joint segments would accommodate any additional articulation demanded of them during normal motion by virtue of the fused segment's immobility. While this is true over the short-term (provided only one, or at most two, segments have been fused), the effects of this increased range of articulation demanded of these adjacent segments has recently become a concern. Specifically, an increase in the frequency of returning patients who suffer from degeneration at adjacent levels has been reported.

"Whether this increase in adjacent level deterioration is truly associated with rigid fusion, or if it is simply a matter of the individual patient's predisposition to degeneration is unknown. Either way, however, it is clear that a progressive fusion of a long sequence of vertebrae is undesirable from the perspective of the patient's quality of life as well as from the perspective of pushing a patient to undergo multiple operative procedures.

"While spine arthroplasty has been developing in theory over the past several decades, and has even seen a number of early attempts in the lumbar spine show promising results, it is only recently that arthroplasty of the spine has become a truly realizable promise. The field of spine arthroplasty has several classes of devices. The most popular among these are: (a) the nucleus replacements, which are characterized by a flexible container filled with an elastomeric material that can mimic the healthy nucleus; and (b) the total disc replacements, which are designed with rigid baseplates that house a mechanical articulating structure that attempts to mimic and promote the healthy segmental motion.

"Among these solutions, the total disc replacements have begun to be regarded as the most probable long-term treatments for patients having moderate to severe lumbar disc degeneration. In the cervical spine, it is likely that these mechanical solutions will also become the treatment of choice. At present, there are two devices being tested clinically in humans for the indication of cervical disc degeneration. The first of these is the Bryan disc, disclosed in part in U.S. Pat. No. 6,001,130. The Bryan disc is comprised of a resilient nucleus body disposed in between concaval-covex upper and lower elements that retain the nucleus between adjacent vertebral bodies in the spine. The concaval-convex elements are L-shaped supports that have anterior wings that accept bones screws for securing to the adjacent vertebral bodies.

"The second of these devices being clinically tested is the Bristol disc, disclosed substantially in U.S. Pat. No. 6,113,637. The Bristol disc is comprised of two L-shaped elements, with corresponding ones of the legs of each element being interposed between the vertebrae and in opposition to one another. The other of the two legs are disposed outside of the intervertebral space and include screw holes through which the elements may be secured to the corresponding vertebra; the superior element being secured to the upper vertebral body and the inferior element being attached to the lower vertebral body. The opposing portions of each of the elements comprise the articulating surfaces that include an elliptical channel formed in the lower element and a convex hemispherical structure disposed in the channel.

"As is evident from the above descriptions, the centers of rotation for both of these devices, which are being clinically tested in human subjects, is disposed at some point in the disc space. More particularly with respect to the Bryan disc, the center of rotation is maintained at a central portion of the nucleus, and hence in the center of the disc space. The Bristol disc, as a function of its elongated channel (its elongated axis being oriented along the anterior to
posterior direction), has a moving center of rotation which is at all times maintained within the disc space at the rotational center of the hemispherical ball (near the top of the upper element).

"Thus, there remains a need for improved intervertebral discs, as well as new and improved methods for safely and efficiently implanting intervertebral discs."

In addition to obtaining background information on this patent, NewsRx editors also obtained the inventors' summary information for this patent: "Disclosed herein are intervertebral discs or implants, surgical instruments and procedures in accordance with certain preferred embodiments of the present invention. It is contemplated, however, that the implants, instruments and procedures may be slightly modified, and/or used in whole or in part and with or without other instruments or procedures, and still fall within the scope of the present invention. Although the present invention may discuss a series of steps in a procedure, the steps can be accomplished in a different order, or be used individually, or in sub-groupings of any order, or in conjunction with other methods, without deviating from the scope of the invention.

"In certain preferred embodiments of the present invention, a method of inserting an intervertebral disc into a disc space includes accessing a spinal segment having a first vertebral body, a second vertebral body and a disc space between the first and second vertebral bodies, securing a first pin to the first vertebral body and a second pin to the second vertebral body, and using the first and second pins for distracting the disc space. The method preferably includes providing an inserter holding the intervertebral disc, engaging the inserter with the first and second pins, and advancing at least a portion of the inserter toward the disc space for inserting the intervertebral disc into the disc space, wherein the first and second pins align and guide the inserter toward the disc space.

"In certain preferred embodiments, the inserter desirably includes an inserter head having an upper channel and a lower channel. During the advancing step, the first pin is preferably in contact with the upper channel and the second pin is preferably in contact with the lower channel. The channels may taper inwardly toward one another for urging the first and second pins away from one another as the inserter advances toward the disc space (preferably to more fully open the disc space as the inserter advances toward the disc space). In certain preferred embodiments, the inserter head has a distal end adapted to contact vertebral bone and a proximal end, and the upper and lower channels taper inwardly toward one another between the proximal and distal ends of the inserter head. As a result, the channels are closer together near the distal end of the inserter than near the proximal end of the inserter. In preferred embodiments, the inserter head includes distally extending arms for securing an intervertebral disc implant. Each of the distally extending arms may include an inwardly extending projection engageable with the intervertebral disc implant.

"In other preferred embodiments of the present invention, a method of inserting an intervertebral disc implant into a disc space includes accessing a spinal segment having a first vertebral body, a second vertebral body and a disc space between the first and second vertebral bodies, securing a first pin to the first vertebral body and a second pin to the second vertebral body, and using the first and second pins for distracting the disc space. The method may include engaging a chisel guide having a distal head with the first and second pins, and advancing the chisel guide toward the disc space for inserting the distal head of the chisel guide into the disc space, whereby the first and second pins align and guide the chisel guide as the chisel guide advances toward the disc space. The method may also include coupling a chisel having one or more cutting blades with the chisel guide and advancing the one or more cutting blades toward the first and second vertebral bodies for forming channels in one or more endplates of the first and second vertebral bodies. The distal head of the chisel guide preferably has a top surface with at least one groove formed therein for guiding the one or more chisel blades toward the disc space. The bottom surface of the head may also have at least one groove for guiding the
chisel.

"The method may also include providing an inserter holding an intervertebral disc implant, and after forming channels in the one or more endplates of the first and second vertebral bodies, disengaging the chisel guide from the first and second pins and engaging the inserter with the first and second pins. The inserter is preferably advanced toward the disc space for inserting the intervertebral disc implant into the disc space, whereby the first and second pins align and guide the inserter as the inserter advances toward the disc space.

"In other preferred embodiments of the present invention, a kit includes a plurality of two-part intervertebral disc implants having different sizes, and a plurality of implant dispensers, each implant dispenser holding together the two parts of one of the two-part intervertebral disc implants so that it can be manipulated as a single implantable unit. Each implant dispenser preferably has indicia corresponding to the size of the intervertebral disc implant held by the implant dispenser. The indicia on the implant dispenser may include a color code or text indicating the size of the intervertebral disc implant held by the implant dispenser.

"In particular preferred embodiments, each intervertebral disc implant has a top element including a bone engaging surface and an articulating surface and a bottom element including a bone engaging surface and an articulating surface. The implant dispenser desirably holds the articulating surfaces of the top and bottom elements in contact with one another.

"The implant dispensers may be flexible. In preferred embodiments, an implant dispenser includes a first arm engaging a top element of the intervertebral disc implant, a second arm engaging a bottom element of the intervertebral disc implant, and a connecting element for interconnecting the first and second arms. The connecting element is preferably flexible for enabling the first and second arms to move away from one another for releasing the intervertebral disc.

"The kit may also include a plurality of inserters, the inserters being adapted to couple with the intervertebral disc implants while the intervertebral disc implants are held in the implant dispensers, so that the intervertebral disc implants can be transferred from the implant dispensers to the inserters. Each inserter preferably has indicia corresponding to the size of a corresponding one of the intervertebral disc implants. The indicia on the inserter may include a color code or text. The intervertebral disc implants are preferably transferable from the implant dispensers to the inserters while being maintained as a single implantable unit. In certain preferred embodiments, an implant inserter will couple directly to the intervertebral disc implant while the disc implant is held by an implant dispenser.

"In other preferred embodiments of the present invention, a template for marking score lines on a spinal segment includes a shaft having a proximal end and a distal end, and a template marker provided at the distal end of the shaft. The template marker preferably includes a cruciform-shaped structure having a first vertical arm and a second vertical arm that extends away from the first arm, the first and second vertical arms being aligned with one another along a first axis. The cruciform-shaped structure also preferably includes a first lateral arm and a second lateral arm extending away from the first lateral arm, the first and second lateral arms being aligned with one another along a second axis, whereby distal surfaces of the first and second lateral arms form a concave curved surface that conforms to an anterior surface of a disc between superior and inferior vertebral bodies.

"The template may include a central pin or a plurality of pins provided at the distal end of the lateral arms for being inserted into the natural disc for stabilizing the template adjacent the disc space, and the vertical arms and the lateral arms spread outwardly from the distal end of the shaft. The first vertical arm desirably includes a first distally extending tack for engaging an anterior surface of the first vertebral body and the second vertical arm desirably
includes a second distally extending tack for engaging an anterior surface of the second vertebral body.

"In certain preferred embodiments of the present invention, each of the top and bottom elements of the implant has an anterior wall that preferably connects the anterior ends of the protrusions on the element. The anterior wall preferably serves as a vertebral body stop to prevent over-insertion of the implant and/or posterior migration of the implant. The anterior wall preferably serves as an engageable feature for engagement with instruments, including but not limited to tamps, extraction or repositioning instruments. The anterior wall in some embodiments may have a curved posterior face to sit flush against a curved anterior endplate face. At least the posterior surface of the wall may be coated with an osteoconductive material to facilitate long-term fixation to the endplate surface.

"In certain preferred embodiments of the present invention, the intervertebral disc implants includes a top element and a bottom element. Each implant part may have protrusions with outwardly laterally facing surfaces. One or more of the outwardly laterally facing surfaces may have a vertically extending channel, or groove, or depression, or like feature for engagement with instruments, including but not limited to insertion, extraction or repositioning instruments. Preferably, the surface of this feature can be coated with an osteoconductive material to facilitate long-term fixation to the endplate bone.

"In certain preferred embodiments, the intervertebral disc implant, or the instruments, may alternatively or additionally incorporate any or all of the features discussed previously, disclosed herein, or discussed in U.S. patents and/or patent applications incorporated by reference herein. Preferably, the configuration of the bearing surfaces of the intervertebral disc implant in this preferred embodiment may be substantially similar to those of the other bearing surface configurations discussed previously, disclosed herein, or incorporated by reference herein.

"Prior to insertion of the intervertebral disc implant disclosed herein, a surgeon preferably performs a cervical anterior exposure and initial natural disc removal (e.g., discectomy). After simple exposure and initial natural disc removal, the surgeon may introduce a guide, such as a reference pin drill guide that enables the surgeon to anchor a pair of alignment or reference pins (e.g., Caspar pins) into the adjacent vertebral bones, preferably along the midline of the bones, and at predetermined vertical distances from the endplate edges.

"The present application discloses the use of reference or alignment pins for properly aligning tooling and/or implants with bone. The reference or alignment pins shown herein are merely representative examples of certain preferred embodiments of the present invention. It is contemplated that other reference or alignment tools and techniques may be used for properly aligning tools and/or implants with bone, and that these other reference or alignment tools and techniques are within the scope of the present invention.

"With the reference pins in place, the surgeon may apply distraction to the disc space by using a distraction tool, such as a standard Caspar distractor, and then complete the discectomy and distraction. Once the disc space is cleared and restored to a desired height, the surgeon may choose to remove the distraction tools and advance a guide, such as a burr or drill guide along the reference pins and into the disc space. The burr or drill guide preferably engages the reference pins as the burr/drill guide is advanced toward the disc space. Thus, the reference pins serve to provide proper alignment of the burr/drill guide relative to the disc space. In certain preferred embodiments, the burr/drill guide includes a distal head that fits within the disc space. The burr/drill guide preferably permits the surgeon to introduce a burr or drill bit through each of four holes in the guide and burr or drill pilot grooves or holes at predetermined locations in the endplates. As will be described in more detail below, the pilot grooves are used
to form protrusion channels for the protrusions of the intervertebral disc.

"In certain preferred embodiments of the present invention, in order to cut protrusion channels in the endplates, a chisel guide may be utilized. The chisel guide preferably includes a distal head that is insertable into the disc space. The distal head preferably has grooves formed in top and bottom surfaces of the distal head for guiding a chisel for cutting protrusion channels. The chisel guide preferably has alignment openings for sliding over the reference pins. The reference pins preferably align and direct the chisel guide into the disc space. Chisels may then be advanced along the sides of the chisel guide for cutting the protrusion channels. In certain preferred embodiments of the present invention, a first pair of chisels (e.g., roughening chisels) is advanced along the sides of chisel guide to cut channels. Preferably, the first pair of chisels cuts channels that are approximately 1 mm wide. A second pair of larger chisels (e.g., finishing chisels) can be used to widen the protrusion channels, preferably to about 2 mm. In other preferred embodiments of the present invention, a first pair of chisels is approximately 1 mm wide and 1.5 mm high, and a second pair of chisels (e.g., the finishing chisels) are 1.5 mm wide and 2.5 mm high.

"Once the protrusion channels have been cut, the implant may be mounted to an insertion tool (e.g., to the distal tip of an insertion tool) and inserted into the disc space. The insertion tool preferably includes upper and lower guide slots or openings that permit the insertion tool to slide along the reference pins. The guide slots are preferably ramped so that the disc space is distracted (to preferably approximately 2 mm wider than the height of the implant) to ensure easy insertion of the implant. In other preferred embodiments, the reference pins may also be engaged by a distraction tool to distract the disc space during insertion, e.g., if such distraction is necessary. This additional distraction may ensure that the device is implanted easily without requiring excessive impacting.

"Once the intervertebral disc implant has been inserted into the disc space, a tamping instrument may be used to adjust the final position of the disc components relative to one another and/or relative to the vertebral bones. Should the surgeon want to remove the device intra-operatively, or in the case of a revision, a proximal feature of the device (e.g., an anterior wall) may be engaged by an instrument (e.g., an extraction instrument) to pull the device free from the disc space.

"In other preferred procedures, after simple exposure and initial disc removal, the surgeon may introduce a guide, such as a reference pin grill guide, that permits the surgeon to drill guide holes in superior and inferior vertebral bodies (preferably parallel to one another) for the placement of the pair of reference pins. A second guide, such as a sleeve or reference pin driver guide may be used to ensure that the reference pins are placed in the pre-drilled holes so that the pins are parallel, and are driven into the adjacent vertebral bones preferably along the midline of the bones, and at predetermined distances from the endplates.

"With the reference pins in place, the surgeon may apply distraction to the disc space, e.g., by means of a distraction tool, and then complete the discectomy and distraction. The surgeon should preferably remove any anterior or posterior osteophytes that may interfere with the ultimate placement of the implant.

"It should be noted that features and methods and functionalities of the present invention, including but not limited to features and methods and functionalities for engaging one tool (or parts thereof) with one or more other tools (or parts thereof) or with the implants (or parts thereof), and vice-versa; for addressing, avoiding, manipulating, or engaging the patient's anatomy; for aligning one or more tools with anatomic or non-anatomic reference points; and for aligning the tools and implants with one another and/or a treatment space; are not and should not be limited to those embodied in and achieved by the structures and methods of the specific
embodiments described and shown, but rather the structures and methods of the specific embodiments described and shown are merely examples of structures and methods that can achieve certain features and methods and functionalities of the present invention.

"These and other preferred embodiments of the present invention will be described in more detail below."

MicroVention, Inc.

Patent Issued for Intracorporeal Occlusive Device and Method (USPTO 9526505)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- According to news reporting originating from Alexandria, Virginia, by NewsRx journalists, a patent by the inventors Marks, Michael P. (Hillsborough, CA); Ross, Michael (Hillsborough, CA), filed on November 20, 2008, was published online on December 27, 2016.

The assignee for this patent, patent number 9526505, is MicroVention, Inc. (Tustin, CA).

Reporters obtained the following quote from the background information supplied by the inventors: "The present invention is generally directed to occlusion devices and, more specifically, to intracorporeal occlusion devices which can be used to treat a patient's blood vessels, intracorporeal conduits or other portions of a patient's body. A preferred embodiment can be used to treat intracranial aneurysms, arteriovenous fistulas, and other abnormalities within the cerebral vasculature.

"Cerebral aneurysms and other cerebral vascular abnormalities present a significant medical problem to the population of the United States. It is estimated that the number of ruptured intracranial aneurysms yearly is in the tens of thousands, often with devastating consequences for the patient. For a patient who has been diagnosed with a cerebral aneurysm, there are a few treatment modalities currently available. An invasive surgical treatment can be used where access to the external portion of the aneurysm is achieved by placing the patient under general anesthesia, performing a craniotomy, and brain tissue retraction. Once access has been gained to the external surface of the aneurysm, the neck of the aneurysm can be clipped. Clipping the aneurysm neck prevents the ingress of blood into the aneurysm cavity which can lead to rupture. Because of the invasive nature of the procedure and the vulnerability of the brain tissue surrounding the aneurysm, this procedure carries a high degree of risk with concomitant mortality and morbidity rates. This risk is particularly high when the aneurysm has
ruptured prior to the surgical intervention.

"An alternative to the surgical method currently in use involves percutaneous endovascular intervention. This method generally involves accessing the cerebral aneurysm by means of an intravascular microcatheter which is advanced under fluoroscopic imaging over a guidewire or the like within the patient's arteries from a puncture site in the patient's leg or arm. The distal end of the microcatheter is guided over a guidewire within a patient's vasculature and disposed adjacent the neck of the aneurysm. The distal tip of the microcatheter can then be directed into the cavity of the aneurysm and appropriate occlusive devices then delivered from a port in the distal end of the microcatheter. Presently, the most common occlusive device delivered via microcatheter is a vaso-occlusive coil which consists of stainless steel or radiopaque metals such as gold or platinum, tantalum. The vaso-occlusive coils are typically manufactured in a manner similar to the distal coils of a coronary guidewire, having a coil wire material with a small diameter and a coil outer diameter suitable for delivery through a microcatheter. Such vaso-occlusive coils are often given a secondary shape or configuration whereby the coils can be straightened and delivered through the inner lumen of a microcatheter, but form a convoluted or random space filling structure once delivered from the distal end of the microcatheter. The endovascular delivery of vaso-occlusive coils through a microcatheter represents a significant advance in treating cranial aneurysms. However, the coils are hollow bodies, often made of relatively soft metals which are subject to compaction due to the pressure exerted on the deployed coils by the patient's blood flow. Compaction and reforming of the coils leaves them susceptible to dislodging and being displaced within the patient's vasculature, with the potential for causing distal embolization. In addition, compaction of the coils into the dome of the aneurysm or blood clot surrounding the coils can lead to reappearance and regrowth of the aneurysm. Finally, aneurysms with wide necks having a dome to neck dimension ratio of less than 2 to 1 often do not provide a morphology conducive to retention of coils within the aneurysm. Thus currently available coils are generally contraindicated for use in wide neck aneurysms. What has been needed is an intracorporeal space filling device which can be delivered by non-invasive methods, is not subject to compaction or reforming and which is suitable for implantation in wide neck aneurysms."

In addition to obtaining background information on this patent, NewsRx editors also obtained the inventors' summary information for this patent: "The invention is directed generally to an intracorporeal space filling device and a delivery system for positioning and deploying the space filling device within a patient. The invention is also directed to a method for using the space filling device.

"One preferred embodiment of the invention is an intracorporeal space filling device which has an elongate tubular shell with a lumen disposed within the shell. The lumen is in fluid communication with a first port in a first end of the shell, and a second port in a second end of the shell. A transmutable material is disposed within the lumen of the shell substantially filling the lumen. The transmutable material has properties which enable transformation from a non-rigid state to a substantially rigid state within a patient's body. The transmutable character of the transmutable material allows for a space filling device that is soft and flexible at the time of deployment into an intracorporeal cavity and rigid and substantially incompressible after being converted to a rigid state. Such a device can conform readily to the varied morphology of intracorporeal cavities and transmute to a substantially rigid mass upon activation or hardening of the transmutable material so as to be resistant to compression and reforming due to vascular or other types of pressures within a patient's body.

"The elongate shell is generally made of a polymeric wall material and is sealed at either or both of the first and second ends. The transmutable material which fills the lumen of the shell can be selected from a variety of suitable polymers which can be made rigid or
hardened by the application of a variety of energy types, such as light emitted from a laser or other source, radiofrequency energy, ultrasonic energy or other suitable means such as controlled changes in the pH of the material surrounding the transmutable material. The space filling device is typically configured for percutaneous delivery through a suitable microcatheter from an incision in a peripheral artery in a patient's arm or leg to a desired intracorporeal cavity, such as a cerebral aneurysm.

"Optionally, the space filling device may have an elongated longitudinal member secured to and preferably coextensive with the elongate tubular shell of the device. Typically, the elongated longitudinal member is a thin wire member that may or may not be configured to give a secondary shape to the space filling device when in an unconstrained relaxed state. The secondary shape of the longitudinal member can be a convoluted, folded, coiled or twisted configuration or any other suitable space filling configuration when in an unconstrained state which is imparted to the intracorporeal space filling device to which the elongated longitudinal member is secured. When the device is in a linear constrained state or configuration, it may be advanced through an inner lumen of a microcatheter or other similar device for delivery to a desired site within a patient's body. Once the space filling device is removed from the constraint of the microcatheter, it again assumes the space filling secondary shape. The elongated longitudinal member can be made from a variety of suitable materials, including stainless steel and shape memory alloys such as nickel titanium (NiTi). The elongated longitudinal member can be disposed along a longitudinal axis of the space filling device, embedded in the transmutable material, encapsulated within the wall material of the elongate tubular shell, or adjacent an outside surface of the elongate tubular shell or any other suitable location on the device. Preferably the elongate longitudinal member is substantially parallel to the longitudinal axis of the elongate shell or intracorporeal space filling device. The elongated longitudinal member can also be configured to be heated by the passage of various types of energy therethrough. For example, an elongated longitudinal member made of NiTi alloy can be configured to be heated by the passage of electrical current, including radiofrequency, or ultrasonic energy through it. Heating of the elongated longitudinal member can be used to transmute or rigidify the transmutable material within the elongate shell and to act as a mechanism for detachment of the intracorporeal space filling device from the distal end of the delivery system.

"In a preferred embodiment, the elongate tubular shell is configured to have an outer surface which is self adhering to create attachment points from contact point upon activation of the self adhering outer surface. Contact points along the length of the space filling device inevitably occur when the device is deployed within an intracorporeal cavity or channel and the space filling device assumes a folded or convoluted space filling configuration. The folded or convoluted space filling configuration may be due to the confinement of the void or channel, a secondary shape assumed by the device in a relaxed state, or both. The creation of attachment points results in a more rigid and stable space filling mass that is resistant to compaction and reforming.

"The intracorporeal space filling device may optionally have a helical coil disposed about an outer surface of the elongate tubular shell. The helical coil may have properties similar to those discussed above with regard to the elongated longitudinal member. For example, the helical coil can be configured to impose a convoluted, folded or space filling secondary shape on the space filling device when in a relaxed unconstrained state. The helical coil may also be configured to heat or otherwise activate transmutation of the transmutable material when various forms of energy are passed through it such as electrical current, ultrasonic energy or the like. The materials of the helical coil may also be similar to those discussed above with regard to the elongated longitudinal member.
"In an alternative embodiment, the space filling device has a transmutable material disposed about an elongated longitudinal member without an outer shell so that the transmutable material is exposed when the device is deployed within a patient's body. The elongated longitudinal member can have properties similar to those of the elongated longitudinal members discussed above. For example, the elongated longitudinal member can be made of a thin wire with a secondary shape. The secondary shape can be imparted on the space filling device when the device is in an unconstrained state. Secondary shapes can include convoluted or folded space filling configurations. Exposure of an outside surface of the transmutable material allows the transmutable material to adhere to itself upon transmutation at attachment points where different portions of the space filling device make contact due to the secondary shape assumed. When the space filling device is deployed in an intracorporeal cavity and assumes a folded, bunched or convoluted configuration due to a secondary shape of the elongated longitudinal member or the natural confinement of the cavity, inevitably, certain portions of the space filling device will make physical contact with other portions of the device. As such, the transmutable material of these portions will make contact at contact points and will cross-link, bond, or self adhere to each other to form attachment points upon transmutation of the transmutable material. The cross-linking or bonding of the device at attachment points results in a rigid mass which is resistive to compression and reforming. The self adhering property of the outside surface of the transmutable material can be as a result of the intrinsic properties of the transmutable material, or as a result of a coating applied to the transmutable material with self adhering properties.

"In another embodiment, the intracorporeal space filling device has a plurality of beads connected to at least one adjacent bead by a flexible member with connections to adjacent beads being configured to produce a linear array of the beads. Each bead has a transverse dimension and is generally spaced within one transverse dimension of adjacent beads, however, other appropriate spacings are possible. The space filling device of interconnected beads is generally configured for percutaneous delivery through a microcatheter or the like from an incision in a peripheral artery of a patient to a desired cavity within the patient's vasculature such as a cerebral aneurysm. The individual beads typically have a generally spherical shape, but can also be substantially elliptical or elongated. The beads can be made from any suitable material, but are preferably made from a polymer material, and more preferably a transmutable polymer material. In a particular embodiment, the beads may have an outer shell which defines a cavity which optionally contains suitable filler material. Suitable filler materials include biocompatible fluids such as a saline, silicone and the like, and polymers such as a transmutable material similar to the transmutable material discussed above.

"Embodiments with beads of exposed transmutable material can be cross-linked or bonded to adjacent beads which are in contact at the time of transmutation at a desired site within a patient's body. Adjacent beads in contact while deployed within a desired location within a patient can adhere or bond together and create attachment points upon transmutation of the transmutable material. The attachment points create a more stable and rigid mass than would be achieved by transmutation of the beads without attachment points.

"The flexible member connecting adjacent beads may consist of interconnected portions of a polymer wall material of the outer shell of each adjacent bead. The flexible member may also be an elongated longitudinal member disposed substantially along a longitudinal axis of the space filling device and being substantially coextensive with at least two adjacent beads of the space filling device. In embodiments of the space filling device having a flexible member consisting of an elongated longitudinal member, the elongated longitudinal member may be a thin wire, preferably of a shape memory alloy. The thin wire longitudinal member can be configured to be heated by a passage of energy through it in order to activate transmutation of transmutable material disposed thereon. The elongated longitudinal member
may also be configured to have a secondary shape or space filling configuration in a relaxed state as discussed above with regard to other elongated longitudinal members. The secondary shape or space filling configuration of the elongated longitudinal member would be imparted to the space filling device as a whole when in an unconstrained relaxed state.

"The intracorporeal space filling devices discussed above are generally deployed at a desired site within a patient's body by disposing the distal end of a microcatheter or the like such that a distal port in the distal end of the microcatheter is directed to a desired cavity or channel within a patient. The space filling device is then distally advanced within the inner lumen of the microcatheter, preferably by means of a delivery system which has an elongate shaft with a detachment mechanism disposed on the distal end of the system. The detachment mechanism is detachably secured to a first end of the space filling device which provides a detachable connection and allows for remote advancement and retraction of the space filling device within the patient prior to detachment. The space filling device is then distally advanced out of a port in the distal end of the microcatheter and into the cavity or channel of the patient. When the space filling device is appropriately positioned, the transmutable material within the device is activated so as to be hardened or rigidified, and the device detached from the delivery system. Preferably, the space filling device is detached by a detachment mechanism utilizing degradation of a polymer link between the delivery system and the first end of the space filling device. Degradation of the polymer link may be accomplished by a chain cleavage reaction which can be initiated by heating of the polymer link. Alternative detachment mechanisms include mechanical detachment, electrolytic detachment, detachment by shape memory alloy or shape memory polymer activation via application of RF energy, laser energy or ultrasonic energy, heating of a hot melt adhesive joint, ultrasonic link degradation, hydrokinetic pressure activation of a mechanical retention device, and the like.

"During deployment of a space filling device, a blocking balloon may be deployed adjacent the opening of an intracorporeal void and distal end of a microcatheter disposed within the void prior to distally advancing the space filling device from the distal end of the microcatheter into the cavity. The blocking balloon prevents egress of the space filling device from within the cavity during deployment of the device.

"These and other advantages of the invention will become more apparent from the following detailed description of the invention when taken in conjunction with the accompanying exemplary drawings."

Our reports deliver fact-based news of research and discoveries from around the world. Copyright 2017, NewsRx LLC
2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A patent by the inventor Lentz, David Christian (Bloomington, IN), filed on January 15, 2014, was published online on December 27, 2016, according to news reporting originating from Alexandria, Virginia, by NewsRx correspondents.

Patent number 9526872 is assigned to Cook Medical Technologies LLC (Bloomington, IN).

The following quote was obtained by the news editors from the background information supplied by the inventors: "Angioplasty and other surgical techniques that utilize the natural body passageways of a patient to gain access percutaneously to a site to be treated have seen great success. As techniques have improved and medical technology has advanced, these procedures, such as angioplasty, have been performed in ever smaller branches of the circulatory system. For instance, it is now even recognized that angioplasty procedures can be performed in an artery in the lower leg of a patient.

"In a typical procedure, access to the patient's circulatory system is gained using the Seldinger technique. In other words, a puncture through the skin and through the wall of a vein or artery is made followed by entry of a small wire guide through the needle. The needle is then withdrawn leaving the wire guide in place. Next, a dilator and introducer are slid over the wire and into the vein or artery. The dilator is then withdrawn leaving only the introducer in place. FIG. 8 shows a prior art procedural step during treatment of a location 8 in an artery 6 of a patient's leg 5 after placement of an introducer 11 through a puncture site 7. With the access to the patient passageway now secured, fluoroscopic techniques may be utilized to gain access to a desired treatment location 8, such as a plaque build up in a artery, remote from the puncture entry site 7. This may be accomplished by injecting radiopaque dye into the patient's circulatory system while a physician 80 manipulates a guide wire guide 40 slid through the introducer 11. While under fluoroscopic vision, the wire guide 40 is maneuvered so that its distal end is at or near the area 8 to be treated. Physician 80 will often manipulate wire guide 40 with one hand 82 while holding the introducer 11 in place with their other hand 81. Because of the size of the fluoroscopic area footprint 70 and the nearness of the treatment location 8 to the entry site 7, the physician may undergo exposure to direct radiation during this portion of the procedure because their hands 81 and 82 as well as their head 83 may be located within the fluoroscopic area 70. After wire guide 40 has been properly positioned, a guide catheter may be slid over the wire guide so that its distal end is at or near the treatment site 8. Next, a balloon dilation catheter may be slid through the guide catheter to the desired treatment location 8. The balloon may be inflated to push back the plaque at the problem location to reopen the passageway for good blood flow. Finally, the balloon catheter is deflated and withdrawn from the patient, followed by withdrawal of the introducer 11 and closure of the entry site 7.

"During the fluoroscopic portion of the treatment, direct radiation passes through the patient in an area 70 that generally includes the area 8 to be treated along with some of the arteries 6 and passageways that must be traversed in order to gain access to the treatment site 8. However, in some instances, such as gaining access to an artery in the lower leg 5 via an antigrade stick, the access location 7 and the treatment location 8 may be sufficiently close that the exposed proximal end of the introducer 11 and the site 8 to be treated may both lay within the fluoroscopic area 70 that experiences direct radiation. While short term exposure to
fluroscopy for the patient poses little risk, a physician performing hundreds of these interventions a year will be exposed unnecessarily to direct radiation that may cumulatively result in permanent tissue damage. When performing such a procedure, the physician's 80 hands 81, 82 and eyes (head 83) will temporarily be exposed to direct radiation while manipulating the wire guide 40 to gain access to a treatment site 8. Because of the risks involved with exposure to direct radiation, physicians are generally less inclined to perform procedures that require direct radiation exposure.

"The present disclosure is directed toward one or more of the problems set forth above."

In addition to the background information obtained for this patent, NewsRx journalists also obtained the inventor's summary information for this patent: "In one aspect, an introducer assembly includes an introducer with a distal segment sized to be received through a puncture site and into a passageway within a patient, and a proximal segment with a fitting having a male luer. An extension includes a flexible tube extending between a first fitting with a female luer, and a second fitting with a male luer. The female luer of the extension is connected to the male luer of the introducer.

"In another aspect, a method of positioning a wire guide at a desired location in a passageway of a patient includes positioning a distal segment of an introducer through a puncture site into the passageway of the patient while a proximal segment extends outside the patient. An extension is connected to the proximal segment of the introducer. Radiopaque dye is injected into the passageway. The desired location for treatment and at least a portion of the introducer are positioned in a fluroscopic area while a proximal end of the extension is outside of the fluroscopic area. A wire guide is maneuvered through the extension and the introducer into the passageway, and toward the desired location from a location outside of the fluroscopic area while passing radiation through the fluroscopic area.

"In still another aspect, an introducer set includes a dilator mated to an introducer. An extension includes a flexible tube extending between a first fitting with a male luer and a second fitting with a female luer. The length between the male luer and the female luer of the extension being in a range of ten to thirty centimeters. The introducer, the dilator and the extension are sterile and sealed in a peel open package."

THE REGENTS OF THE UNIVERSITY OF...

Patent Issued for LEDGF Peptides and Formulations Thereof for Treatment of Degenerative Disorders (USPTO 9526760)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- THE REGENTS OF THE UNIVERSITY OF COLORADO, A BODY CORPORATE (Denver, CO) has been issued patent number 9526760, according to news
reporting originating out of Alexandria, Virginia, by NewsRx editors.

The patent's inventors are Kompella, Uday B. (Aurora, CO); Baid, Rinku (Aurora, CO); Upadhyay, Arun K. (Aurora, CO); Yandrapu, Sarath (Christianburg, VA).

This patent was filed on May 21, 2013 and was published online on December 27, 2016.

"The unique anatomy and physiology of the eye is a major hurdle in the advancement of drug therapeutic for the back of the eye including retinal degenerative diseases. (Kompella et al., Ther Deliv. 1(3): p. 435-56). Topical routes of administration are inefficient in delivering drugs to the back of the eye because of the presence of various static barriers (cornea, conjunctiva, and sclera among others tissues) and dynamic barriers (blinking, tear film, tear turnover, and induced lacrimation). (Gaudana, R., et al., Ocular drug delivery. Aaps J, 2010. 12 (3): p. 348-60; Thrimawithana et al. Drug Discov Today, 2011. 16(5-6): p. 270-7). On the other hand blood retinal barrier (BRB), systemic degradation, systemic side effects, and low concentrations at target site are major challenges for the intravenous route. Other routes such as intra cameral, periocular, subretinal have their own subset of problems sharing some issues in common with topical and systemic route of administration (Baid et al. Drug Development and the back of the eye. ed. Kompella UB. 2010, p. 409-448: Springer). Local delivery such as an intravitreal injection places the drug to close proximity to the retina (the target tissue for retinal degenerative diseases) and thus is the most effective route in delivering drug to retina. However, frequent intravitreal injections of the drug leads to various complications such as retinal detachment, retinal hemorrhage, endophthalmitis, increased intraocular pressure, and not to mention patient compliance and infections. (Peyman et al. Retina, 2009. 29(7): p. 875-912; Wu et al. Semin Ophthalmol, 2009. 24(2): p. 100-5). Thus there is a need of for compositions and delivery system that can extend the retention of drugs in the eye.

"Novel drug delivery systems have gained major attention which could sustain or control the release of drug for extended period of time as well as increase the stability and bioavailability of therapeutic agents such as proteins, genes and other small molecules. Biodegradable (PLGA, PCL) and non-biodegradable (e.g Vitraset and Retisert) implants provides a platform for sustaining release of drug over several months to years. However, erratic drug release profile for biodegradable implants and requirement of highly invasive eye surgery are few drawbacks. Micro and nanoparticles provide sustained release of encapsulated molecules for weeks to months. However, use of organic solvents such as dichloromethane during preparation denatures and reduces protein efficacy leading to non-effective treatment. Further encapsulation efficiency, controlled particles size, and sterility during preparations are among the other hurdles. Iontophoresis, microneedles, ultrasound based ocular deliver have also been tried, however, the major advances are with the small molecule drugs and still are in
investigation stage and needs validations to establish their efficacy and safety. Thus non- or minimally-invasive, controlled, and sustained delivery to the posterior segment is becoming extremely vital with escalating advances in the emerging therapies for retinal degenerations."

Supplementing the background information on this patent, NewsRx reporters also obtained the inventors' summary information for this patent: "The present invention is directed to biologically active peptides of LEDGF that can be produced in high quantity, purity, or both. For example, the present invention is directed to peptides of LEDGF that can be produced at, or greater than, 20 mg per liter of culture and at, or greater than, 90% purity as quantified by SDS-PAGE and SEC-HPLC. In one exemplary embodiment the peptide is approximately a 40 kDa monomer, that may exist as an 80 kDa dimer. In another exemplary embodiment, the peptide has primarily a random coil structure and includes an N-terminal stress related binding domain, and optionally a TAT binding domain.

"In another exemplary embodiment, the peptide comprises amino acids 1-326 of LEDGF (LEDGF.sub.1-326). In yet another exemplary embodiment, the peptide comprises SEQ ID NO: 2. In another exemplary embodiment, the peptide comprises an amino acid sequence with at least 70%, at least 75%, at least 80%, at least 85%, at least 90%, or at least 95% sequence identity with SEQ ID NO: 2. In addition, the present invention includes nucleic acid sequences encoding SEQ ID NO: 2, or nucleic acid sequences encoding amino acid sequences having at least 70%, at least 75%, at least 80%, at least 85%, at least 90%, or at least 95% sequence identity with SEQ ID NO: 2. The present invention further includes vectors containing such nucleic acid sequences. In one exemplary embodiment, the vector is a pET-28a (+) vector.

"In another aspect, the present invention comprises compositions containing the LEDGF peptides. In one exemplary embodiment, the composition comprises the LEDGF peptide in combination with a pharmaceutical carrier, diluent, excipient, or combination thereof. In another exemplary embodiment, the composition comprises the LEDGF peptide associated with or bound to colloidal metal particles, such as zinc, to form nano-assemblies. In yet another exemplary embodiment, the compositions comprise the LEDGF peptide encapsulated or bound to an inner particle loaded into a porous outer particle. In certain exemplary embodiments, the LEDGF peptide used in the above compositions is LEDGF.sub.1-326.

"In another aspect, the present invention is directed to methods of treating protein aggregation-mediated diseases by administering the above LEDGF peptide compositions to a patient in need thereof. In certain exemplary embodiments, the protein aggregation-mediated disease is a retinal degeneration disease. Exemplary retinal degeneration diseases include, but are not limited to, age related macular degeneration (AMD) retinitis pigmentosa (RP) and diabetic retinopathy (DR). In another exemplary embodiment, the protein aggregation-mediated diseases are neurodegenerative diseases including, but not limited to, Alzheimer's disease (AD), Parkinson's disease (PD), Huntington's disease (HD), amyotrophic lateral sclerosis, or a prion disease."

Patent Issued for Lipidated Glycosaminoglycan Particles and Their Use in Drug and Gene Delivery for Diagnosis and Therapy (USPTO 9526705)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A patent by the inventors Margalit, Rimona (Givatayim, IL); Peer, Dan (Qiryat Ono, IL), filed on January 7, 2016, was published online on December 27, 2016, according to news reporting originating from Alexandria, Virginia, by NewsRx correspondents.

Patent number 9526705 is assigned to TEL-AVIV UNIVERSITY FUTURE TECHNOLOGY DEVELOPMENT L.P. (Tel-Aviv, IL).

The following quote was obtained by the news editors from the background information supplied by the inventors: "Glycosaminoglycans, or mucopolysaccharides, along with collagen, are the chief structural elements of all connective tissues. Glycosaminoglycans, or gags, are large complexes of polysaccharide chains associated with a small amount of protein. These compounds have the ability to bind large amounts of water, thereby producing a gel-like matrix that forms the body's connective tissues. Gags are long chains composed of repeating disaccharide units (aminosugar-acidic sugar repeating units). The aminosugar is typically glucosamine or galactosamine. The aminosugar can also be sulfated. The acidic sugar may be D-glucuronic acid or L-iduronic acid. In vivo, gags other than hyaluronic acid are covalently bound to a protein, forming proteoglycan monomers. The polysaccharide chains are elongated by the sequential addition of acidic sugars and aminosugars.

"Among the most common gags are hyaluronic acid, keratan sulfate, chondroitin sulfate, heparin sulfate, and dermatan sulfate. Gags may be chemically modified to contain more sulfur groups than in their initially extracted form. In addition, gags may be partially or completely synthesized and may be of either plant or animal origin.

"Hyaluronic acid is a naturally occurring member of the glycosaminoglycan family which is present in particularly high concentration in the cartilage and synovial fluid of articular joints, as well as in vitreous humor, in blood vessel walls, and umbilical cord and other connective tissues. Hyaluronic acid can be in a free form, such as in synovial fluid, and in an attached form, such as an extracellular matrix component. This polysaccharide consists of alternating N-acetyl-D-glucosamine and D-glucuronic acid residues joined by alternating beta-1,3-glucuronidic and beta-1,4-glucosaminidic bonds. In water, hyaluronic acid dissolves to form a highly viscous fluid. The molecular weight of hyaluronic acid isolated from natural sources generally falls within the range of 5.times.10.sup.4 up to 10.sup.7 daltons. Hyaluronic acid has a high affinity for the extracellular matrix and to a variety of tumors, including those of the breast, brain, lung, skin, and other organs and tissues.

"A drug delivery system is used for maintaining a constant blood level of a drug over a long period of time by administering a drug into the body, or for maintaining an optimal concentration of a drug in a specific target organ by systemic or local administration, and over a prolonged period of time.

"Chemically modified hyaluronic acid can be used for controlled release drug delivery. Balazs et al, in U.S. Pat. No. 4,582,865, state that 'cross-linked gels of hyaluronic
acid can slow down the release of a low molecular weight substance dispersed therein but not covalently attached to the gel macromolecular matrix.’

"Various forms of pharmaceutical preparations are used as drug delivery systems, including the use of a thin membrane of a polymer or the use of a liposome as a carrier for a drug.

"There are two basic classes of drug carriers: particulate systems, such as cells, microspheres, viral envelopes, and liposomes; and non-particulate systems, which are usually soluble systems, consisting of macromolecules such as proteins or synthetic polymers.

"Generally, microscopic and submicroscopic particulate carriers have several distinct advantages. They can perform as sustained-release or controlled-release drug depots, thus contributing to improvement in drug efficacy and allowing reduction in the frequency of dosing. By providing protection of both the entrapped drug and the biological environment, these carriers reduce the risks of drug inactivation and drug degradation. Since the pharmacokinetics of free drug release from the particles are different from directly-administered free drug, these carriers can be used to reduce toxicity and undesirable side effects.

"Despite the advantages offered, there are some difficulties associated with using drug encapsulating biopolymers. For example, biopolymers structured as microparticulates or nanoparticles have limited targeting abilities, limited retention and stability in circulation, potential toxicity upon chronic administration, and the inability to extravasate. Numerous attempts have been made to bind different recognizing substances, including antibodies, glycoproteins, and lectins, to particulate systems, such as liposomes, microspheres, and others, in order to confer upon them some measure of targeting. Although bonding of these recognizing agents to the particulate system has met with success, the resulting modified particulate systems did not perform as hoped, particularly in vivo.

"Other difficulties have also arisen when using such recognizing substances. For example, antibodies can be patient-specific, and thereby add cost to the drug therapy. Additionally, not all binding between recognizing substrate and carrier is covalent. Covalent bonding is essential, as non-covalent binding might result in dissociation of the recognizing substances from the particulate system at the site of administration, due to competition between the particulate system and the recognition counterparts to the target site for the recognizing substance. Upon such dissociation, the administered modified particulate system can revert to a regular particulate system, thereby defeating the purpose of administration of the modified particulate system."

In addition to the background information obtained for this patent, NewsRx journalists also obtained the inventors' summary information for this patent: "It is an object of the present invention to overcome the deficiencies in the prior art.

"It is another object of the present invention to form glycosaminoglycan-based particles for encapsulating drugs.

"It is another object of the present invention to deliver drugs encapsulated in a glycosaminoglycan-based particle.

"It is a further object of the present invention to provide methods of drug delivery using particles of lipidated glycosaminoglycans as the drug delivery vehicles.

"In a preferred embodiment, the delivery is by oral administration of the particle formulation. In another preferred embodiment, the delivery is by intranasal administration of the particle formulation, especially for use in therapy of the brain and related organs (e.g., meninges and spinal cord) that seeks to bypass the blood-brain barrier (BBB). Along these lines, intraocular administration is also possible. In another preferred embodiment, the delivery means is by intravenous (i.v.) administration of the particle formulation, which is especially
advantageous when a longer-lasting i.v. formulation is desired.

"It is still another object of the present invention to provide gene delivery using particles of lipitated glycosaminoglycans as the gene delivery materials.

"The present invention provides a novel multi-product gene and drug delivery technology as well as methods of preparation and uses thereof. The delivery system comprises lipitated glycosaminoglycans, also known as gagomers, which are bioadhesive biopolymers produced by cross-linking a lipid having a primary amino group to a carboxylic acid-containing glycosaminoglycan. Micro- or nanoparticles are formed in a controlled manner, with dominant particle diameter ranges of about 2-5 microns for microparticles and about 50-200 nanometers for nanoparticles. Either small or large drugs, bioactive agents, or active ingredients such as antibiotics, chemotherapeutics, proteins, and nucleic acids can be entrapped in these particles with high efficiency, usually greater than 50%, even for large macromolecules. For example, for plasmid DNA the nanoparticles provide about 66% entrapment and the microparticles provide about 75% entrapment.

"For purposes of the present invention, 'drug' means any agent which can affect the body therapeutically, or which can be used in vivo for diagnosis. Examples of therapeutic drugs include chemotherapeutics for cancer treatment, antibiotics for treating infections, and antifungals for treating fungal infections. Examples of diagnostic drugs include radioactive isotopes such as 99Tc, 127I, and 67Gd, and fluorescent molecules which are used in visualizing sites of interest in the body.

"Preparation of the biopolymers of the present invention and drug entrapment are simple and cost-effective processes. These novel carriers act as sustained release drug depots, with half-lives in the range of 19–35 hours for the efflux of antibiotics and chemotherapeutics. These properties, together with their bioadhesive nature, provide these novel drug carriers the ability to perform as site-adherent, site-retained, sustained release drug depots for systemic, including oral, topical, and regional, including intranasal, administrations.

"Additionally, the gagomers of the present invention are non-toxic. When chemotherapeutic drugs were entrapped and tested in a cell culture model, the systems exhibited high potential in tumor treatment, even overcoming the well known impediment of drug resistance. Thus, the gagomers can be used as microscopic and submicroscopic drug delivery systems for a wide range of therapeutic activities, such as cancer, infectious diseases, wound healing, enzyme therapy, gene therapy, and others.

"Unexpectedly, the empty particles (containing only gagomers and no drug or other therapeutic formulation) also appear to have important tumor-inhibiting effects. Therefore, such particles may be useful for cancer therapy, especially for metastatic cancer, either as a main or adjuvant chemotherapeutic agent."

Arrowhead Pharmaceuticals, Inc.

**Patent Issued for Low Density Lipoprotein Receptor-Mediated siRNA Delivery (USPTO 9526799)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Arrowhead Pharmaceuticals, Inc. (Pasadena, CA) has been issued patent number 9526799, according to news reporting originating out of Alexandria, Virginia, by NewsRx editors.

The patent's inventor is Chatterton, Jon E. (Aliso Viejo, CA).

This patent was filed on February 9, 2016 and was published online on December 27, 2016.

From the background information supplied by the inventors, news correspondents obtained the following quote: "RNA interference (RNAi) is a process by which double-stranded RNA (dsRNA) is used to silence gene expression. RNAi is induced by short (i.e. <30 nucleotide) double stranded RNA (dsRNA) molecules which are present in the cell (Fire et al., 1998, Nature 391:806-811). These short dsRNA molecules called 'short interfering RNA' or 'siRNA,' cause the destruction of messenger RNAs (mRNAs) which share sequence homology with the siRNA to within one nucleotide resolution (Elbashir et al., 2001, Genes Dev, 15:188-200). It is believed that one strand of the siRNA is incorporated into a ribonucleoprotein complex known as the RNA-induced silencing complex (RISC). RISC uses this siRNA strand to identify mRNA molecules that are at least partially complementary to the incorporated siRNA strand, and then cleaves these target mRNAs or inhibits their translation. The siRNA is apparently recycled much like a multiple-turnover enzyme, with 1 siRNA molecule capable of inducing cleavage of approximately 1000 mRNA molecules. siRNA-mediated RNAi degradation of an mRNA is therefore more effective than currently available technologies for inhibiting expression of a target gene.

"RNAi provides a very exciting approach to treating and/or preventing diseases. Some major benefits of RNAi compared with various traditional therapeutic approaches include: the ability of RNAi to target a very particular gene involved in the disease process with high specificity, thereby reducing or eliminating off target effects; RNAi is a normal cellular process leading to a highly specific RNA degradation and a cell-to-cell spreading of its gene silencing effect; and RNAi does not trigger a host immune response as in many antibody based therapies.

"Several interfering RNA delivery methods are being tested/developed for in vivo use. For example, siRNAs can be delivered 'naked' in saline solution; complexed with polycations, cationic lipids/lipid transfection reagents, or cationic peptides; as components of defined molecular conjugates (e.g., cholesterol-modified siRNA, TAT-DRBD/siRNA complexes); as components of liposomes; and as components of nanoparticles. These approaches have shown varying degrees of success. Thus, there is a need for new and improved methods for delivering siRNA molecules in vivo to achieve and enhance the therapeutic potential of RNAi."

Supplementing the background information on this patent, NewsRx reporters also obtained the inventor's summary information for this patent: "The invention provides interfering RNA molecule-ligand conjugates, wherein the ligand can bind to a low density lipoprotein receptor (LDLR) or LDLR family member. The invention also provides methods of using the conjugates for delivering an interfering RNA molecule into a cell in vitro or in vivo. In one aspect, an interfering RNA molecule-ligand conjugate of the invention can be used to deliver an interfering RNA molecule to an eye of a patient."
"The invention further provides methods of treating or preventing an ocular disorder in a patient, comprising administering to the patient an interfering RNA molecule-ligand conjugate, wherein the ligand can bind to a low density lipoprotein receptor (LDLR) or LDLR family member and wherein the interfering RNA molecule can attenuate expression of a gene associated with the ocular disorder. In certain aspects, the ocular disorder is or is associated with ocular angiogenesis, dry eye, ocular inflammatory conditions, ocular hypertension, or glaucoma. In other aspects, the conjugate is administered by intraocular injection, subconjunctival injection, intravitreal injection, anterior or posterior juxtascleral injection, ocular topical application, intravenous injection, oral administration, intramuscular injection, intraperitoneal injection, transdermal application, intranasal application, or transmucosal application.

"Specific preferred embodiments of the invention will become evident from the following more detailed description of certain preferred embodiments and the claims."

superconducting ring, or the like.

"FIGS. 6A and 6B are schematic diagrams of magnetic flux detecting coils showing an example of the SQUID in the related art. FIG. 6A is a diagram showing a magnetic flux detecting coil (magnetometer), which is wound once. FIG. 6B is a diagram showing a magnetic flux detecting coil that two parallel coils wound in opposite directions to each other are connected in series (first-order gradient type gradiometer).

"As shown in FIG. 6A, in a magnetometer 101, a magnetic field 110 coming into the coil is totally detected. Therefore, in order to detect only a magnetic field (for example, cardiac magnetism or cerebral magnetism) generated from near the coil, it is necessary to prepare a separate method of completely eliminating a noise by a magnetic field having the source distant from the coil (for example, external magnetic noise).

"As shown in FIG. 6B, in a first-order gradient type gradiometer 102, the magnetic field 110 is detected as a difference of detection signals detected from the two coils wound in the opposite directions to each other. For this reason, the influence of the magnetic field having the source distant from the coils is negated and becomes zero between the two coils, and only the magnetic field generated from near the coils is detected. However, the SQUID costs are high because a superconducting device or a Josephson device is used. In addition, the SQUID needs an effort because it is necessary to frequently supply liquid helium or liquid nitrogen to a cooling system in order to maintain a low temperature environment.

"On the other hand, there is an optically-pumped atomic magnetometer as a method of measuring a micro-magnetic field without using the SQUID. The optically-pumped atomic magnetometer is an apparatus that measures a magnetic field by detecting a magnetization state of an atom by causing an atom and a magnetic field to interact with each other using an optical pumping method (a method in which an electron spin of atoms is polarized using polarized light and the polarized atoms are detected with high sensitivity). For example, in Appl. Phys. B75, 605-612 (2002) and Appl. Phys. B76, 325-328 (2003), two laser beams having polarization directions different from each other are incident on a gas cell into which alkali metal atoms such as cesium and the like are injected, the two laser beams transmitted through the gas cell are each received with two photodetectors to detect light intensities. After that, optical signals detected by the two photodetectors are converted into electric signals to calculate a difference in intensity variations of the laser beams, and thereby measuring a micro-magnetic field excluding an influence of an external magnetic field.

"However, in the Appl. Phys. B75, 605-612 (2002) and Appl. Phys. B76, 325-328 (2003), there is a case where a noise occurs when optical signals detected by the two photodetectors are converted into electric signals to calculate a difference in intensity variations of the laser beams, and thereby causing difficulties to measure a micro-magnetic field with high accuracy. In addition, since two photodetectors are used as detectors, the structure of a magnetic sensor is complicated and the calculation also becomes complicated."

In addition to the background information obtained for this patent, NewsRx journalists also obtained the inventor's summary information for this patent: "An advantage of some aspects of the invention is to provide a magnetic sensor that enables the measurement of a micro-magnetic field with high accuracy and achieves a simplified structure.

"According to an aspect of the invention, there is provided a magnetic sensor for measuring a magnetic field using an optical pumping method including a first gas in which a valence electron is composed of an odd number of atoms or ions, a probe light source which causes first circular polarized light to be incident on the first gas, a second gas in which a valence electron arranged on an optical path of second circular polarized light that is the first circular polarized light transmitted through the first gas is composed of an odd number of atoms
or ions, an AC magnetic field generator which generates an AC magnetic field in a direction intersecting with an optical axis of the first circular polarized light and the second circular polarized light for the first gas and the second gas and generates magnetic resonance, a bias magnetic field generator which generates bias magnetic fields in a direction parallel to the optical axis of the first circular polarized light and the second circular polarized light with different intensities for the first gas and the second gas and differentiates the optical transmittance of the first circular polarized light in the first gas from the optical transmittance of the second circular polarized light in the second gas, and a detector which detects a light amount of the first circular polarized light and third circular polarized light that is the second circular polarized light transmitted through the second gas.

"With the configuration, by generating magnetic resonance and a gradient magnetic field to the first gas and the second gas, the optical transmittance of the circular polarized light is different in the first gas and the second gas. In addition, the light amount of the circular polarized light before/after the light is transmitted through the first gas and the second gas is detected. Accordingly, a difference between the optical transmittance of the circular polarized light in the first gas and the optical transmittance of the circular polarized light in the second gas is obtained. Then, a difference between the magnetic field applied to the first gas and the magnetic field applied to the second gas is calculated. As a result, the influence of an external magnetic field for the first gas and the influence of an external magnetic field for the second gas offset each other, and thereby, only a measuring target magnetic field applied to the first gas is measured. In other words, the calculation of a difference in optical signals is performed without converting the optical signals into electric signals as in Appl. Phys. B75, 605-612 (2002) and Appl. Phys. B76, 325-328 (2003). In addition, since two photodetectors are not used as detectors, the structure of the magnetic sensor is simple and the calculation becomes smooth. Therefore, it is possible to provide the magnetic sensor that enables the measurement of a micro-magnetic field with high accuracy and achieves a simplified structure.

"Furthermore, according to the above aspect of the invention, there is provided the magnetic sensor in which the bias magnetic field generator generates a bias magnetic field so that the intensity of a bias magnetic field in the first gas is greater than that of a bias magnetic field in the second gas.

"With the configuration, the optical transmittance in the first gas and the second gas is assuredly different. Therefore, it is possible to provide the magnetic sensor that assuredly enables the measurement of a micro-magnetic field with high accuracy and achieves a simplified structure.

"Furthermore, according to the above aspect of the invention, there is provided the magnetic sensor in which the bias magnetic field generator may generate a bias magnetic field so that the intensity of the bias magnetic field in the second gas is greater than that of the bias magnetic field in the first gas.

"With the configuration, the optical transmittance in the first gas and the second gas is assuredly different. Therefore, it is possible to provide the magnetic sensor that assuredly enables the measurement of a micro-magnetic field with high accuracy and achieves a simplified structure.

"Furthermore, according to the above aspect of the invention, there is provided the magnetic sensor in which the first gas and the second gas may be injected into the same cell.

"With the configuration, since the first gas and the second gas are injected into the same cell, the structure of the device is simpler than a case where the first gas and the second gas are injected into difference cells. In addition, when the first gas and the second gas are injected into difference cells, the alignments of the optical axis of the probe light and each cell
have to be performed separately from each other, but when the first gas and the second gas are injected into the same cell, such alignment is completed for one time, and therefore, the setting becomes easy."

THE BOARD OF TRUSTEES OF THE UNIVERSITY...

Patent Issued for Mandelic Acid Condensation Polymers (USPTO 9527793)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- THE BOARD OF TRUSTEES OF THE UNIVERSITY OF ILLINOIS (Urbana, IL) has been issued patent number 9527793, according to news reporting originating out of Alexandria, Virginia, by NewsRx editors.

The patent's inventors are Anderson, Jr., Robert A. (Chicago, IL); Diao, Xiao-Hui (Chicago, IL); Zaneveld, Lourens J. D. (Sao Paulo, BR); Chany, II, Calvin J. (Dubuque, IA); Krunic, Aleksej (Chicago, IL); Waller, Donald P. (Oak Brook, IL); Venton, Duane L. (Lombard, IL); Jain, Sanjay (Pune, IN).

This patent was filed on November 30, 2012 and was published online on December 27, 2016.

From the background information supplied by the inventors, news correspondents obtained the following quote: "The HIV/AIDS epidemic has significantly and dramatically underscored the threat of STDs to the human population. Until there is a cure, or at least an effective treatment, the best, and perhaps only realistic, approach to this increasing problem of STDs (especially HIV/AIDS) appears to be reducing the risk of transmission of STDs by the causative pathogens and thus reducing the number of new infections. Even when STD treatments or cures become available, prevention will likely remain as the first line of defense for economic and medical reasons.

"At present, education in regard to STDs, their modes of transmission, and so-called 'safe-sex' techniques has, at least to some degree in the more developed countries, shown promise in reducing the risks of STD transmission through sexual activity. Screening of the blood supply has helped to reduce the risk of transmission of such STD-causing organisms via blood transfusions and related medical practices. Nonetheless, the spread of such STDs has not been halted to a satisfactory degree even in developed countries with active and progressive education programs. Even with their known effectiveness in preventing STDs, current safe-sex techniques are not always used, or are not always used properly, for many reasons (e.g., carelessness, lack of knowledge, improper techniques, cultural barriers, unplanned or spontaneous sexual activity, and the like). Moreover, even when used correctly, safe-sex techniques are not always effective. Various birth control devices--including barrier methods..."
and vaginal contraceptives--are currently available. Some of these may, in addition, also have a least some degree of anti-STD activity.

"Sexually transmitted diseases, especially HIV/AIDS, also present risks to health care providers and laboratory personnel working with STD-infected patients and/or blood and tissue samples from such patients. Physical contact with the bodily fluids of infected patients can, especially if there are breaks or cuts in the skin, increase the risk of transmission of the STD-causing organisms. In recent years, such health care providers and laboratory personnel have increasingly donned protective clothing and equipment when working with patients or biological samples where exposure to bodily fluids is possible. Latex gloves (often double or triple layered), goggles, protective clothing, and the like are often used when treating or examining patients in both medical and dental offices or working with biological samples from patients (e.g., blood, tissue, and the like). In spite of these precautions, exposure to bodily fluids can still occur. For example, sudden movement by a patient while having a blood sample withdrawn can cause blood to splatter and, perhaps, come in contact with an unprotected part of the body of other persons in the area; needle punctures or scalpel cuts can expose health-care providers to bodily fluids in spite of gloves and other protective layers; or aerosols containing blood and/or saliva can be generated during dental procedures which may contact the body of other persons. Although contact with unbroken and healthy skin is unlikely to result in transmission of the STD, breaks, cuts, or damage to the protective skin layer can increase the risk of transmission.

"Treatments are available for many STDs subsequent to infection, but such infections are increasingly showing resistance to available treatments. For example, HIV can become drug resistant to convention antiretroviral therapies. This phenomenon is well established and is monitored by the WHO in developing countries. In the Unites States, 50% of HIV patients receiving treatment are known to be infected with a strain of HIV that expresses resistance to at least one known treatment drug. In one study, nearly 30% of new HIV infections in one region of Africa were of a drug-resistant strain. The particular drug had been introduced only 18 months earlier. Patients with HIV must be monitored for such drug resistance and are typically on a cocktail of drugs to maintain suppression of the infection. Not only can a sexually active person become infected with an already drug resistant strain, but once infected and under treatment, HIV can mutate and thus become resistant to further treatment.

"Accordingly, what is needed are improved compounds, compositions, and methods for reducing the risk of STD infections. It would be desirable if such compounds, compositions, and methods would not interfere with the natural and protective vaginal mechanisms so as to maintain the naturally protective vaginal flora and maintain integrity of vaginal and cervical tissues, yet prevent pathogens from infecting host cells such as macrophages and CD4+ cells. It would also be desirable if such compounds, compositions, and methods would be relatively easy to use and have significantly fewer side effects than currently available products so that it would more likely be used on a consistent basis. It would also be desirable if such compounds, compositions, and methods could be used in heterosexual, homosexual, and bisexual relationships and for a wide range of sexual activities. It would also be desirable if such compounds, compositions, and methods could be implemented by either party to the sexual activity. It would also be desirable to provide compounds, compositions, and methods by which the risk of infection by sexually transmitted diseases, especially HIV/AIDS, could be reduced for individuals working with patients and/or biological samples."

Supplementing the background information on this patent, NewsRx reporters also obtained the inventors' summary information for this patent: "In one aspect, compounds having formula (I) are disclosed,
or a pharmaceutically acceptable salt, ester, amide, or prodrug form thereof,

wherein

R.sup.1, R.sup.2, and R.sup.3 are each independently selected from the group consisting of hydrogen, alkyl, alkenyl, alkynyl, cycloalkyl, heterocycle, heteroaryl, aryl, and counterion;

R.sup.4 is independently selected from the group consisting of hydrogen, alkyl, alkenyl, alkynyl, cycloalkyl, heterocycle, heteroaryl, and aryl;

R.sup.5, R.sup.6, and R.sup.7 are each independently selected from the group consisting of alkyl, alkoxy, hydroxy, and halogen;

n is an integer greater than zero; and

x, y, and z are each an integer independently selected from the group consisting of 0, 1, 2, 3, and 4.

In another aspect, compounds having repeating units of formula (II) are disclosed,

or a pharmaceutically acceptable salt, ester, amide, or prodrug form thereof,

wherein

R.sup.2 is independently selected from the group consisting of hydrogen, alkyl, alkenyl, alkynyl, cycloalkyl, heterocycle, heteroaryl, aryl, and counterion.

In another aspect, disclosed are compositions comprising a compound of the invention and a pharmaceutically acceptable carrier. Preferably, the compositions are adapted for topical use as protective agents against transmission of one or more sexually transmitted diseases, and in particular, HIV/HSV.

In yet another aspect, disclosed is a process for producing a compound of the invention. In one embodiment, the process comprises cooling a strong acid to a temperature below 0.degree. C., preferably below -10.degree. C., more preferably below -25.degree. C., and most preferably below about -30.degree. C.; and adding mandelic acid or a mandelic acid derivative to the strong acid to provide a reaction mixture. In another embodiment, the process comprises providing a reaction mixture comprising mandelic acid or a mandelic acid derivative and a strong acid, wherein the reaction mixture is at a reduced temperature ranging from about -45.degree. C. to about -5.degree. C., preferably from about -35.degree. C. to -30.degree. C.

In another aspect, disclosed is a method for reducing the risk of infection. In one embodiment, the method comprises applying to the body or portion of the body of an individual an effective amount of a protective agent, wherein the protective agent comprises a compound of the invention. In another embodiment, the method comprises contacting a pathogen or cells susceptible to infection by the pathogen with an effective amount of a compound of the invention, thereby reducing the risk of transmission of the pathogen.

"The compounds, compositions, methods and processes are further described herein."

Patent Issued for Materials and Methods for Quality-Controlled Two-Color RT-QPCR Diagnostic Testing of Formalin Fixed Embedded And/Or Fresh-Frozen Samples (USPTO 9528161)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A patent by the inventors Willey, James C. (Toledo, OH); Yeo, Jiyoun (Maumee, OH); Crawford, Erin (Rossford, OH), filed on February 11, 2015, was published online on December 27, 2016, according to news reporting originating from Alexandria, Virginia, by NewsRx correspondents.

Patent number 9528161 is assigned to The University of Toledo (Toledo, OH).

The following quote was obtained by the news editors from the background information supplied by the inventors: "Reverse transcription quantitative real-time polymerase chain reaction (RT-qPCR) tests that measure transcript abundance of selected genes in clinical specimens have been demonstrated to increase cancer diagnostic accuracy and enable 'personalized medicine' through selection of the most effective treatment for each cancer."

"There are challenges to using such methods, however, and these methods do not work well when the amount of sample is small or when the sample contains degraded RNA.

"A particular challenge is that current clinical pathology sample collection and processing procedures focus on formalin fixation and paraffin embedding (FFPE) and fresh/fresh-frozen tissues rarely are available for molecular analysis. FFPE samples are difficult to work with because they yield RNA that 1) often contains PCR-interfering substances, and 2) is uniformly highly fragmented and often in low abundance. Economic factors prevent changing this workflow to ensure collection of samples in a form more conducive to molecular genetic analysis, such as fresh-frozen, therefore, there is a need to develop methods that are sufficiently robust to reliably conduct molecular genetic analysis in FFPE samples. These RT-qPCR tests must be able to assess FFPE samples with quality control and inter-laboratory reproducibility."

In addition to the background information obtained for this patent, NewsRx journalists also obtained the inventors' summary information for this patent: "Described herein are materials, methods, and kits enabling accurate and reproducible two-color reverse-transcription real-time quantitative PCR (RT-qPCR) for quality-controlled molecular diagnostic testing of samples that may contain degraded RNA.

"In a particular embodiment described herein is a kit for use in molecular diagnostic testing of a sample, comprising a) synthetic competitive internal standards (IS), wherein known quantities of each IS are formulated into an internal standards mixture (ISM); b) an external standards mixture (ESM) comprising 1) purified synthetic native template (NT), and 2) synthetic competitive internal standards (IS), wherein known quantities of each purified synthetic NT and IS are formulated into the ESM; c) pairs of gene-specific primers (GSP) specific to specific genes and primers; and d) sequence-specific fluorometric hydrolysis probes, wherein all fluorometric hydrolysis probes are labeled with a fluorescent reporter."
"Another particular embodiment provided herein provides a method for using a kit described herein, comprising the steps of: a) extracting RNA from a sample; b) reverse-transcribing (RT) the RNA extracted from the sample; c) pre-amplifying cDNA generated by the RT of the RNA extracted from the sample along with the ISM, wherein the pre-amplification of the cDNA and ISM is done by polymerase chain reaction (PCR) using the pairs of GSP specific to the genes; d) performing a second round of PCR amplification for the genes, wherein a reaction mixture for a single gene comprises: 1) a dilution of the pre-amplified cDNA and ISM; 2) a primer mixture comprising the pairs of GSP corresponding to the genes; and 3) fluorometric hydrolysis probes specific for the single gene NT and corresponding IS; e) along with the second round of PCR amplification, for each gene, simultaneously performing PCR amplification on two distinct concentrations of the ESM, wherein each distinct concentration of ESM further comprises the same fluorometric hydrolysis probes specific for the single gene NT and corresponding IS of step d) 3); and f) quantifying the copy number for loading the genes (e.g., a control gene and one or more target genes).

"In another particular embodiment provided herein is a method for using a kit described herein, wherein the step of quantifying the copy number for each target gene comprises the steps of: a) calculating the difference in quantification cycle (Cq) between the NT and IS for a target gene using the formula \(\text{NT Cq-IS Cq}_{\text{Target Gene}}\); b) calculating an average difference in Cq between the NT and IS of two concentrations of ESM using the formula \(\frac{\text{NT Cq-IS Cq}_{\text{ESM Concentration 1}} + \text{NT Cq-IS Cq}_{\text{ESM Concentration 2}}}{2} = \text{NT Cq-IS Cq}_{\text{ESM}}\); c) calculating a corrected delta Cq using the formula \(\text{NT Cq-IS Cq}_{\text{Target Gene}} - \text{NT Cq-IS Cq}_{\text{ESM}}\); d) obtaining a target gene NT copy number by multiplying \(2^{-\text{corrected delta Cq}}\) by a known number of input IS copies corresponding to the target gene in the reaction; and e) normalizing the target gene NT copy number to a gene loading control NT value.

"In another particular embodiment provided herein is a method described herein, wherein the samples comprise material having degraded RNA therein.

"In another particular embodiment provided herein is a method described herein, wherein the samples comprise formalin fixed paraffin embedded (FFPE) samples.

"In another particular embodiment provided herein is a method described herein, wherein the samples comprise fresh-frozen samples.

"In a particular embodiment described herein is a kit for use in molecular diagnostic testing of a sample comprising: a) one or more synthetic competitive internal standards (IS), wherein each IS is synthesized to correspond with a unique target gene or reference gene, wherein an IS probe binding site has a 4-6 bp difference than that of a native template (NT), and wherein known quantities of the one or more IS are formulated into an internal standards mixture (ISM); b) an external standards mixture (ESM) comprising: 1) one or more purified synthetic NT, wherein each NT is synthesized to correspond with a unique target gene or reference gene; and 2) one or more synthetic competitive internal standards (IS), wherein each IS is synthesized to correspond with a unique target gene or reference gene, wherein known quantities of each purified synthetic NT and IS are formulated into the ESM; c) one or more pairs of gene-specific primers (GSP), wherein each pair of GSP is specific for a unique target gene or reference gene, and is designed to amplify a PCR product having a product size of approximately 60-80 base pairs and span introns/exon splice junctions of the unique target gene or reference gene; and d) at least one pair of fluorometric hydrolysis probes, wherein each pair of fluorometric probes is specific for a particular target gene or reference gene, and comprises a first fluorometric hydrolysis probe that is sequence-specific for an NT probe binding site and is labeled with a first fluorescent reporter, and a second fluorometric hydrolysis probe that is sequence specific for an IS probe binding site of an IS corresponding to the NT against which
the first fluorometric hydrolysis probe is sequence-specific for, and is labeled with a second fluorescent reporter.

"Another particular embodiment provided herein provides a method for using a kit described herein, comprising the steps of: a) extracting RNA from the sample; b) reverse-transcribing (RT) the RNA extracted from the sample; c) pre-amplifying cDNA generated by the RT of the RNA extracted from the sample along with ISM including IS for each target gene or reference gene, wherein the pre-amplification of the cDNA and ISM is done by polymerase chain reaction (PCR) using the pairs of GSP specific to each target gene or reference gene; d) performing a second round of PCR amplification for each target gene and at least one reference gene, wherein a reaction mixture for a single target gene or reference gene comprises: 1) a dilution of the pre-amplified cDNA and ISM; 2) a primer mixture comprising the one or more pairs of GSP; and 3) one pair of fluorometric hydrolysis probes, specific for a single target gene or reference gene and its corresponding IS; e) along with the second round of PCR amplification, for each target gene or reference gene, simultaneously performing a PCR amplification on two distinct concentrations of the ESM containing the same pair of fluorometric hydrolysis probes used in step d) 3); and f) quantifying the copy number for each target gene.

"In another particular embodiment provided herein is a method for using a kit described herein, wherein the step of quantifying the copy number for each target gene comprises the steps of: a) calculating the difference in quantification cycle (Cq) between the NT and IS for a target gene using the formula\(\text{[NT Cq-IS Cq].sub. Target Gene}\); b) calculating an average difference in Cq between the NT and IS of two concentrations of ESM using the formula \(\frac{\text{[NT Cq-IS Cq].sub.ESM Concentration 1} + \text{[NT Cq-IS Cq].sub.ESM Concentration 2}}{2} = \text{[NT Cq-IS Cq].sub.ESM}\); c) calculating a corrected delta Cq using the formula \(\text{[NT Cq-IS Cq].sub. Target Gene} - \text{[NT Cq-IS Cq].sub.ESM}\); d) obtaining a target gene NT copy number by multiplying \(2^{\text{(-corrected delta Cq)}}\) by the known number of input IS copies corresponding to the target gene in the reaction; and e) normalizing the target gene NT copy number to a reference gene loading control gene NT value.

"Another particular embodiment provided herein provides a method to control for inter-experimental variation occurring during two-color RT-qPCR amplification comprising: a) providing one or more synthetic competitive internal standards (IS), wherein each IS is synthesized to correspond with a unique target gene or reference gene, and wherein known quantities of the one or more IS are formulated into an internal standards mixture (ISM); b) providing an external standards mixture (ESM) comprising: 1) one or more purified synthetic NT, wherein each NT is synthesized to correspond with a unique target gene or reference gene; and 2) one or more synthetic competitive internal standards (IS), wherein each IS is synthesized to correspond with a unique target gene or reference gene, wherein known quantities of each purified synthetic NT and IS are formulated into the ESM; c) while running a two-color RT-qPCR amplification to quantify a target gene using the ISM, simultaneously amplify two distinct concentrations of ESM, wherein the ESM comprises probes for the NT and IS being quantified; d) correcting a measured copy number for one or more target genes by: 1) calculating the difference in quantification cycle (Cq) between NT and IS for a target gene \(\text{([NT Cq-IS Cq].sub. Target Gene)}\); 2) calculating an average difference in Cq between NT and IS of two concentrations of ESM \(\frac{\text{([NT Cq-IS Cq].sub.ESM Concentration 1} + \text{[NT Cq-IS Cq].sub.ESM Concentration 2}}{2} = \text{[NT Cq-IS Cq].sub.ESM}\); 3) calculating the corrected delta Cq using the formula \(\text{[NT Cq-IS Cq].sub. Target Gene} - \text{[NT Cq-IS Cq].sub.ESM}\); 4) obtaining a target gene NT copy number by multiplying \(2^{\text{(-corrected delta Cq)}}\) by the known number of input IS copies corresponding to the target gene in the reaction; and 5) normalizing the target gene NT copy number to a reference gene loading control gene NT value, wherein normalizing the target
gene NT copy number to a reference gene loading control gene NT value controls for inter-
experimental variation occurring during two-color RT-qPCR, as any variation in the observed
[NT Cq-IS Cq]_ESM relative to the expected value of 0 is attributable to the inter-
experimental variation.

"In another particular embodiment provided herein is a method, wherein the two-
color RT-qPCR amplification is being done on cDNA originated from a sample having
degraded RNA therein.

"In another particular embodiment provided herein is a method, wherein the inter-
experimental variation arises from variation in fluorescence specific activity.

"In another particular embodiment provided herein is a method, wherein the inter-
experimental variation arises from the RT-qPCR reaction being conducted on a different
machine.

"In another particular embodiment provided herein is a method, wherein the inter-
experimental variation arises from variation in equipment and procedures between different
laboratories.

"Other systems, methods, features, and advantages of the present invention will be or
will become apparent to one with skill in the art upon examination of the following drawings
and detailed description. It is intended that all such additional systems, methods, features, and
advantages be included within this description, be within the scope of the present invention, and
be protected by the accompanying claims."

Ecolink Intelligent Technology, Inc.
Patent Issued for Method and Apparatus for Detecting a Hazard Alarm
Signal (USPTO 9530298)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness
& Wellness Week -- From Alexandria, Virginia, NewsRx journalists report that a patent by the
inventors Gruber, Brandon (Vista, CA); Seelman, George (Temecula, CA), filed on July 7,
2015, was published online on December 27, 2016.

The patent's assignee for patent number 9530298 is Ecolink Intelligent Technology,
Inc. (Carlsbad, CA).

News editors obtained the following quote from the background information
supplied by the inventors: "I. Field of the Invention

"The present invention relates to home security and, more particularly, to a method
and apparatus for audible/visual detection of conventional consumer smoke or carbon monoxide
II. Description of Related Art

Many homes and businesses contain hazard alarms for detecting the presence of smoke and/or carbon monoxide. Such detectors are typically purchased by consumers at the retail level and installed in their homes and businesses. When a fire or excess carbon monoxide is detected, these detectors typically emit a piercing siren and/or visual effect (e.g., flashing light). However, older people often have hearing or mobility difficulty and remain at a significantly increased risk of injury even if the audible alarm sounds.

Home security monitoring vendors such as Ackerman or ADT.TM. offer networked detectors and failsafe deployment of first responders. Again, when an alarm condition is detected, these systems emit an audible local alarm and also send an alarm code to a central panel for alerting a remote monitoring station, which in turn dispatches proper authorities to the location where the alarm condition exists. However, these network detectors are typically system-specific, and are installed by a third party along with other detectors such as door and window monitors for unauthorized entry. These network systems and their dedicated alarms are expensive and not generally used for middle and low income housing.

Inexpensive consumer smoke or carbon monoxide detectors cannot communicate with home security systems, or vice versa, since these consumer-grade detectors generally lack the capability to wirelessly communicate with a centrally-located security panel. Further, most wireless security panels use proprietary protocols to reduce the ability for third party products to communicate with these panels. Consequently, when a consumer smoke or carbon monoxide detector sounds an alarm and no one is present inside the home, the alarm will not be acted on.

Consequently, there remains a need for an apparatus that would enable network monitoring of consumer-level fire and carbon monoxide alarms.

As a supplement to the background information on this patent, NewsRx correspondents also obtained the inventors’ summary information for this patent: "Accordingly, it is an object of the present invention to provide a method and device for audibly and/or visually detecting activation of a conventional consumer smoke or carbon monoxide detector and for communicating that fact to a network security system for communication with a remote monitoring station.

"It is another object to accomplish the foregoing in an environment where multiple different alarm types may be activated at once, and to be able to discriminate the different alarm types.

"It is another object to accomplish the foregoing with a digital processor-based circuitry and a buffer for storing digital samples on a FIFO basis and for analyzing a contiguous subset of the digital samples stored in buffer memory to detect each cadence patterns.

"In accordance with the foregoing and other objects, the present invention comprises a method and apparatus for detecting an audible and/or visual alarm, typically in the form of a pattern warning signal, generated by one or more hazard alarms, and in response thereto sending an alert signal to a home security panel for notification to a remote monitoring station. Such an apparatus generally comprises an audio and/or visual detection device for converting such pattern warning signals to an analog signal, providing amplification and filtering to the analog signal, then converting it to a digital signal for evaluation by a processor."

For additional information on this patent, see: Gruber, Brandon; Seelman, George. Method and Apparatus for Detecting a Hazard Alarm Signal. U.S. Patent Number 9530298, filed July 7, 2015, and published online on December 27, 2016. Patent Issued for Method and Apparatus for Treating a Carotid Artery (USPTO 9526504)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- From Alexandria, Virginia, NewsRx journalists report that a patent by the inventor Chang, David W. (Sunnyvale, CA), filed on February 13, 2015, was published online on December 27, 2016.

The patent's assignee for patent number 9526504 is Silk Road Medical, Inc. (Sunnyvale, CA).

News editors obtained the following quote from the background information supplied by the inventors: "Field of the Invention

"Certain inventions disclosed herein relate to treating a carotid artery. For example, a carotid artery may have a lesion or a partial occlusion that can be treated using the methods and apparatus disclosed herein.

"Description of the Related Art

"Carotid angioplasty and stenting (CAS) is a minimally invasive approach for treating carotid stenoses. Since its introduction two decades ago, the use of CAS has steadily increased, with 8% of the 107,000 carotid procedures performed in Europe in 2001 utilizing CAS. The prospect of an outpatient procedure without the discomfort of a sizable neck incision appears to be driving patient decision making away from carotid endarterectomy, the standard procedure for carotid bifurcation disease for the past fifty years."

As a supplement to the background information on this patent, NewsRx correspondents also obtained the inventor's summary information for this patent: "One disclosed embodiment comprises an apparatus for use in carotid angioplasty. The apparatus comprises a catheter having a distal end and a proximal end opposite the distal end, and first and second occlusive members, of which at least the first occlusive member is located on the catheter. The first and second occlusive members are configured to reverse the natural direction of blood flow in the internal carotid artery when the first occlusive member occludes the common carotid artery and the second occlusive member occludes the external carotid artery. The catheter has a first shaft portion extending proximally from the first occlusive member. The first shaft portion has a maximum cross-section sized to be insertable into the common carotid artery. The first shaft portion has a relatively short length suitable for transcervical access to the common carotid artery. The catheter has a blood entry port located distal of the first occlusive member. The apparatus further comprises a collection reservoir configured to be connected to the catheter and placed in passive fluid communication with the blood entry port.

"Another disclosed embodiment comprises a method of treating a lesion in a carotid artery in a patient. The method comprises inserting a catheter into the carotid vasculature via a transcervical approach, and occluding blood flow in the common carotid artery and the external carotid artery, thus reversing the direction of natural blood flow in the internal carotid artery.
The method further comprises allowing blood to flow into a blood entry port in the catheter, and passively collecting the blood in a reservoir.

"Another disclosed embodiment comprises an apparatus for use in carotid angioplasty. The apparatus comprises a catheter having a distal end and a proximal end opposite the distal end, and first and second occlusive members, of which at least the first occlusive member is located on the catheter. The first and second occlusive members are configured to reverse the natural direction of blood flow in the internal carotid artery when the first occlusive member occludes the common carotid artery and the second occlusive member occludes the external carotid artery. The catheter has a first shaft portion extending proximally from the first occlusive member. The first shaft portion has a maximum cross-section sized to be insertable into the common carotid artery. The first shaft portion has a relatively short length suitable for transcervical access to the common carotid artery. The catheter has a blood entry port located distal of the first occlusive member. The apparatus further comprises a passive fluid conduit and a collection reservoir. The collection reservoir is configured to be connected to the catheter via the passive fluid conduit.

"Another disclosed embodiment comprises a method for treating lesions in the carotid artery of a mammalian body. The method comprises transcervical access and blocking of blood flow through the common carotid artery to the venous system of the mammalian body and treating the lesion in the carotid artery. The method may optionally further comprise blocking blood flow through the external carotid artery.

"In the method, access to the carotid artery can optionally be obtained percutaneously, or via a cutdown incision, or with any suitable technique. The treating step of the method can optionally include dilating the lesion with a balloon. The treating step of the method can optionally include stenting the dilated lesion. The shunting step of the method can optionally include filtering the blood for debris. The blocking step of the method can optionally include occluding the external carotid artery with a balloon. The blocking step of the method can optionally include occluding the common carotid artery with a balloon. The blocking step of the method can optionally include clamping the common carotid artery. The introducing step of the method can optionally include introducing a single sheath with balloons to occlude the common and external carotid artery and a side port for deployment of an angioplasty balloon or stent. The blocking step of the method can optionally include introducing at least one catheter directly into the common carotid artery. The introducing step of the method can optionally include introducing first and second introducer sheaths directly into the common carotid artery. The introducing step of the method can optionally include introducing first and second balloon catheters directly into the common carotid artery.

"Another disclosed embodiment comprises a method for treating lesions in the carotid artery. The method comprises transcervical access, blocking blood flow through the common carotid artery to allow safe treatment of the lesion and returning blood flow back to the carotid artery. The method may further comprise blocking blood flow through the external carotid artery.

"In the method, the blood in the carotid artery may be actively withdrawn and returned to the carotid artery. In the method, access to the carotid artery can optionally be obtained percutaneously, or via a cutdown incision, or with any suitable technique. The treating step of the method can optionally include dilating the lesion with a balloon. The treating step of the method can optionally include stenting the dilated lesion. The shunting step of the method can optionally include filtering the blood for debris. The blocking step of the method can optionally include occluding the external carotid artery with a balloon. The blocking step of the method can optionally include occluding the common carotid artery with a balloon. The blocking step of the method can optionally include clamping the common carotid artery.
introducing step of the method can optionally include positioning a single sheath with balloons to occlude the common and external carotid artery and a side port for deployment of an angioplasty balloon or stent. The blocking step of the method can optionally include introducing at least one catheter directly into the common carotid artery. The introducing step of the method can optionally include introducing first and second introducer sheaths directly into the common carotid artery. The introducing step of the method can optionally include introducing first and second balloon catheters directly into the common carotid artery.

"Another disclosed embodiment comprises a method for treatment of lesions in the carotid artery. The method comprises transcervical access, blocking blood flow through the common carotid artery and passive collection of blood and debris and subsequent return of filtered blood to the carotid artery. The method may further comprise blocking blood flow through the external carotid artery.

"In the method, access to the carotid artery can optionally be obtained percutaneously, or via a cutdown incision, or with any suitable technique. The treating step of the method can optionally include dilating the lesion with a balloon. The treating step of the method can optionally include stenting the dilated lesion. The shunting step of the method can optionally include filtering the blood for debris. The blocking step of the method can optionally include occluding the external carotid artery with a balloon. The blocking step of the method can optionally include occluding the common carotid artery with a balloon. The blocking step of the method can optionally include clamping the common carotid artery. The introducing step of the method can optionally include positioning a single sheath with balloons to occlude the common and external carotid artery and a side port for deployment of an angioplasty balloon or stent. The blocking step of the method can optionally include introducing at least one catheter directly into the common carotid artery. The introducing step of the method can optionally include introducing first and second introducer sheaths directly into the common carotid artery. The introducing step of the method can optionally include introducing first and second balloon catheters directly into the common carotid artery.

"Certain objects and advantages of the invention are described herein. Of course, it is to be understood that not necessarily all such objects or advantages may be achieved in accordance with any particular embodiment of the invention. Thus, for example, those skilled in the art will recognize that the invention may be embodied or carried out in a manner that achieves or optimizes one advantage or group of advantages as taught herein without necessarily achieving other objects or advantages as may be taught or suggested herein.

"All of the embodiments summarized above are intended to be within the scope of the invention herein disclosed. However, despite the foregoing discussion of certain embodiments, only the appended claims (and not the present summary) are intended to define the invention. The summarized embodiments, and other embodiments of the present invention, will become readily apparent to those skilled in the art from the following detailed description of the preferred embodiments having reference to the attached figures, the invention not being limited to any particular embodiment(s) disclosed."

APERIAM MEDICAL, INC.

Patent Issued for Method and Device for Treatment of Hypertension and Other Maladies (USPTO 9526572)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- From Alexandria, Virginia, NewsRx journalists report that a patent by the inventor Kunis, Christopher Gerard (Escondido, CA), filed on April 26, 2012, was published online on December 27, 2016.

The patent's assignee for patent number 9526572 is APERIAM MEDICAL, INC. (Boise, ID).

News editors obtained the following quote from the background information supplied by the inventors: "Hypertension is a common and dangerous disease and represents a significant global health issue that continues to grow. Present treatments for hypertension typically include lifestyle changes, surgical procedures such as angioplasty, and various drug therapies which can be effective in some cases. However, the overall rate of control of hypertension and the therapeutic efforts to prevent progression of related maladies such as myocardial infarction, heart failure, chronic kidney disease, and diabetic nephropathy remain unsatisfactory and new treatment options are desirable.

"This Background is provided to introduce a brief context for the Summary and Detailed Description that follow. This Background is not intended to be an aid in determining the scope of the claimed subject matter nor be viewed as limiting the claimed subject matter to implementations that solve any or all of the disadvantages or problems presented above."

As a supplement to the background information on this patent, NewsRx correspondents also obtained the inventor's summary information for this patent: "Systems and methods for treating hypertension and other maladies are implemented using an implant device that is configured with one, two, or more coils of ribbon which form ring-like structures when deployed in a patient's vasculature and, in the case of multiple rings or sets of coils, are interconnected via respective extension arms formed from at least one helical-shaped winding. In an illustrative example, a delivery catheter is positioned in the patient's aorta near the right angle junction with renal vasculature so that the axis of the catheter is substantially perpendicular to the axis of the vasculature. Through operation of an implant device delivery system having a pigtail distal end, the ribbon emerges from the catheter tip and coils into the ring-like structures which deploy into the renal vasculature so that the longitudinal axes of the device and vasculature are substantially co-linear.

"In some implementations, the present systems and methods facilitate utilization of an implanted device that has an improved safety profile and which minimizes collateral damage over many current therapies. Therapy is delivered within the vessel having a focal tissue effect at the point of contact. Advantageously, no external energy source or capital investment is required for use with the implant device in many typical implementations. Methods utilized with the implant device need not directly integrate the device into the wall surface of the vessels. Rather, in an acute treatment, the implant device is designed and configured to apply and maintain radial or substantially radial force along the circumference of the vessels in which it is implanted, while employing a helical pattern of extension arms, connecting the two or more
coils, each forming a ring-like structure. The radial force imparted from the implanted device is found to efficaciously block or retard sympathetic nerve communication to the kidneys which is identified as a principle contributor to the pathophysiology of hypertension, kidney disease, and heart failure. The implant device can be configured with multiple rings so that the radial force can be imparted along a target length of renal vasculature. The implant device may further be delivered using a procedure under only local anesthesia rather than requiring general anesthesia.

"This Summary is provided to introduce a selection of concepts in a simplified form that are further described below in the Detailed Description. This Summary is not intended to identify key features or essential features of the claimed subject matter, nor is it intended to be used as an aid in determining the scope of the claimed subject matter."

Keywords for this news article include: Kidney, Anesthesia, Cardiology, Nephrology, Hypertension, Heart Disease, Heart Failure, Pain Medicine, APERIAM MEDICAL INC., Heart Disorders and Diseases, Cardiovascular Diseases and Conditions.

DANISCO US INC.

Patent Issued for Method for Amplifying Locus in Bacterial Cell (USPTO 9528114)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A patent by the inventors Ferrari, Eugenio (Reggioi, IT); Peres, Caroline M. (Palo Alto, CA), filed on March 27, 2009, was published online on December 27, 2016, according to news reporting originating from Alexandria, Virginia, by NewsRx correspondents.

Patent number 9528114 is assigned to DANISCO US INC. (Palo Alto, CA).

The following quote was obtained by the news editors from the background information supplied by the inventors: "Expression and recombinant production of exogenous polypeptides is a widely used technique. It is well known that cells can be transformed with nucleic acids encoding exogenous polypeptides of interest for expression and production of large quantities of the desired polypeptides. In some applications, the methods are used to produce vast amounts of polypeptide over what would be produced naturally by the originating organism. Indeed, expression of exogenous nucleic acid sequences, as well as over-expression of endogenous sequences have been extensively used in modern biotechnology.

"Despite advances in molecular biology and protein engineering, there remains a need for new methods and compositions that increase expression levels of polypeptides in host cells."

In addition to the background information obtained for this patent, NewsRx journalists also obtained the inventors' summary information for this patent: 'Provided herein is a method of amplifying a genomic locus. In certain embodiments, the method may comprise: a) contacting a population of bacterial host cells with an inhibitor of an essential enzyme, where
the bacterial host cells comprise a genomic locus of the structure: A.sub.1-P-M-A.sub.2, where A.sub.1 and A.sub.2 are direct repeats, P comprises a coding sequence for a polypeptide of interest, and M comprises a coding sequence for the essential enzyme, and b) selecting for cells that are resistant to the inhibitor; where cells that are resistant to the inhibitor have multiple copies of the amplification unit. The bacterial host cell may be a Bacillus sp. cell, although other bacterial cell types, e.g., Streptomyces sp., are envisioned. In some embodiments, the polypeptide of interest is a subtilisin e.g. the subtilisin of SEQ ID NO:8, or mature form thereof set forth in SEQ ID NO:12. In certain cases, the method avoids the use of antibiotic markers and antibiotics, and provides an alternative to antibiotic-based amplification systems. In certain embodiments, the essential enzyme has the amino acid sequence of an enzyme e.g. a wild-type enzyme, that is endogenous to the cell. In particular embodiments, the bacterial host cell used in the method may or may not contain an inactivated endogenous gene encoding the essential enzyme, where the inactivated gene may be at a different genomic locus to the genomic locus of structure: A.sub.1-P-M-A.sub.2. In certain cases, the essential enzyme may be alanine racemase e.g. SEQ ID NO:11, and the inhibitor may be .beta.-chloro-D-alanine or cycloserine, although other enzyme/inhibitor combinations may be employed. In some embodiments, the amplification unit comprises the sequence set forth in SEQ ID NO:7.

"The amplification unit provides for expression of the essential enzyme encoded by region M. In particular embodiments, M may comprise a coding sequence and a promoter operably linked to the coding sequence, wherein the promoter is native to the coding sequence for the essential enzyme. In certain embodiments, the coding sequence and the promoter may be endogenous to the host cell. The amplification unit also provides for expression of the protein of interest encoded by region P. In particular embodiments, the coding sequence of P may be operably linked to an endogenous or non-endogenous promoter that is present in the adjacent direct repeat (A.sub.1). In other embodiments, the promoter for P may not be present in the adjacent direct repeat. Rather, the promoter may be present in region P."

"In some embodiments, the invention provides a bacterial host cell comprising a genomic locus comprising an amplification unit of the structure: A.sub.1-P-M-A.sub.2, wherein A.sub.1 and A.sub.2 are direct repeats, P comprises a coding sequence for a polypeptide of interest, and M comprises a coding sequence for an essential enzyme is also provided. In this embodiment, the amplification unit provides for significant expression of the essential enzyme. The bacterial host cell may be a Bacillus sp. cell, although other bacterial cell types, e.g., Streptomyces sp., are envisioned. In some embodiments, the polypeptide of interest is a subtilisin e.g. the subtilisin of SEQ ID NO:8, or mature form thereof set forth in SEQ ID NO:12. In certain cases, the method avoids the use of antibiotic markers and antibiotics, and provides an alternative to antibiotic-based amplification systems. In certain embodiments, the essential enzyme has the amino acid sequence of an enzyme e.g. a wild-type enzyme, that is endogenous to the cell. In particular embodiments, the bacterial host cell may or may not contain an inactivated endogenous gene encoding the essential enzyme, where the inactivated gene may be at a different genomic locus to the genomic locus of structure: A.sub.1-P-M-A.sub.2. In certain cases, the essential enzyme may be alanine racemase e.g. SEQ ID NO:11, and the inhibitor may be .beta.-chloro-D-alanine or cycloserine, although other enzyme/inhibitor combinations may be employed. In some embodiments, the amplification unit comprises the sequence set forth in SEQ ID NO:7.

"In other embodiments, the bacterial host cell of the invention comprises a genomic locus comprising multiple copies of an amplification unit of the structure: A.sub.1-P-M-A.sub.2, where A.sub.1 and A.sub.2 are direct repeats, P comprises a first coding sequence for a polypeptide of interest, and M comprises a second coding sequence of an essential enzyme. In some embodiments, the amplification unit comprises a polynucleotide sequence set forth in SEQ
ID NO:7. In some embodiments, the first coding sequence is operably linked to a promoter that is present in direct repeat A1. In particular embodiments, the bacterial host cell comprises a genomic locus comprising multiple copies an amplification unit described by the formula: 

\[(\text{A.sub.1-P-M}).\text{sub.n-A.sub.2}, \text{where n is at least 2, A.sub.1 and A.sub.2 are direct repeats, P comprises a coding sequence for a polypeptide of interest, and M encodes an essential enzyme, where the coding sequence of M is operably linked to an endogenous or non-endogenous promoter. In one embodiment, the coding sequence of M and the promoter may be endogenous to the host cell. In some embodiments, the bacterial host cell comprises a genomic locus comprising multiple copies e.g. at least 2 copies, of the amplification unit of SEQ ID NO:7. The amplification unit provides for expression of both the polypeptide of interest e.g. a subtilisin, and the essential enzyme. In some embodiments, the expressed polypeptide of interest is subtilisin FNA set forth in SEQ ID NO:8, or mature form thereof set forth in SEQ ID NO:12, and the essential enzyme is alanine racemase set forth is SEQ ID NO:11. In a particular embodiment, the promoter operably linked to the coding sequence of P may be part of the adjacent direct repeat (A.sub.1). In another embodiment, the promoter operably linked to the coding sequence of region P is present in region P rather than in the adjacent direct repeat.

"In another embodiment, the invention encompasses a bacterial cell culture that comprises growth medium and a population of bacterial host cells comprising at least one, at least 2 or more copies of the amplification unit of the structure A.sub.1-P-M-A.sub.2, wherein A.sub.1 and A.sub.2 are direct repeats, P comprises a first coding sequence for a protein of interest, and M comprises a second coding sequence of an essential enzyme. As described above, the amplification unit provides for expression of both the polypeptide of interest e.g. a subtilisin, and the essential enzyme. In some embodiments, the expressed polypeptide of interest is subtilisin FNA set forth in SEQ ID NO:8, or mature form thereof set forth in SEQ ID NO:12, and the essential enzyme is alanine racemase set forth is SEQ ID NO:11. In yet another embodiment, the bacterial cell culture may be employed in a protein production method that comprises: maintaining a culture of subject cells under conditions suitable to produce the polypeptide of interest encoded by the coding sequence. In particular embodiments, this method may further comprise recovering the polypeptide of interest from the culture medium."
inventors Pani, Amar K. (Lakeland, TN); Smeyne, Richard Jay (Collierville, TN), filed on
February 28, 2014, was published online on December 27, 2016.

The patent's assignee for patent number 9528976 is St. Jude Children's Research
Hospital (Memphis, TN).

News editors obtained the following quote from the background information
supplied by the inventors: "Purine and pyrimidine nucleosides and bases, the essential building
blocks of nucleic acids, occur widely throughout the animal kingdom and underlie a number of
critical functions including energy transduction, metabolism and cell signaling. One
endogenous purine nucleoside, adenosine (ADO), plays an important role in a number of
biochemical processes including energy transfer.

"In the nervous system, ADO acts as a non-classical inhibitory neurotransmitter
adenosine or its signaling have been linked to a number of neurological disorders including
schizophrenia (Boison, et al. (2012) Neuropharmacology 62:1527-43), panic disorder and
(2007) Prog. Neurobiol. 83:332-47). Alterations in ADO have also been linked to changes in a

"With the brain, extracellular ADO concentrations have been reported to be in the
(1982) Neurosci. Lett. 29:111-115). However, in response to cellular damage (e.g., seizure or
ischemia), these concentrations can quickly elevate (Zetterstrom, et al. (1982) supra; Berman,
Neurol. 32:618-24), suggesting that ADO, in addition to signaling, also can have a
neuroprotective function.

"Adenosine functions by binding to and signaling through four known receptor
compounds that acts via ADO signaling, and in particular by bind to the A2A receptor, is
caffeine. This drug's stimulatory effects are primarily (although not entirely) credited to its
inhibition of ADO via competitive inhibition of these receptors (Lazarus, et al. (2011) J.
Neurosci. 31:10067-75), effectively blocking adenosine signaling. The subsequent reduction in
ADO signaling leads to increased activity of other neurotransmitters including acetylcholine (Jin

"Conventionally, the ability to directly measure adenosine and its metabolites has
been difficult, and has generally been carried out by proxy. For example, aptamer-based
approaches have been described (Zhou & Zhao (2012) Analyst 137:4262-6; Liu & Yan (2012)
Commun. 31:4747-9), as have label-based (Huang, et al. (2011) Biosens. Bioelectron. 29:178-

"More direct approaches have also been suggested. For example, a combined high pressure liquid chromatography (HPLC) separation and electrochemical detection method has been described for identifying adenosine and guanosine (Henderson & Griffin (1984) J. Chromatograph. A 298:231-42). However, clean-up procedures were suggested to remove interfering material in biological samples. Similarly, a combined reversed-phase HPLC, gradient elution and electrochemical and UV detection method has been described for detecting adenosine, guanosine, inosine, guanine, hypoxanthine, xanthine and urate in mouse brain and serum, as well as in post-mortem human brain (Burdett, et al. (2012) Biomed. Chromatograph. Doi:10.1002/bmc.2760). Moreover, simultaneous detection of dopamine and adenosine has been described using a boron-doped diamond working electrode in combination with HPLC (Birbeck & Mathews (2012) Pittcon 2012, Abstract 1370-3; Birbeck & Mathews (2013) Anal. Chem. 85:7898-404)."

As a supplement to the background information on this patent, NewsRx correspondents also obtained the inventors' summary information for this patent: "The present invention is a method for simultaneously detecting adenosine, and its metabolites, by (i) separating the components of a biological sample by reversed phase high pressure liquid chromatography under isocratic elution conditions; (ii) collecting fractions; and (iii) simultaneously detecting the levels of adenosine, and metabolites thereof, in each fraction with a coulometric electrochemical detector. In one embodiment, the method also includes the step of comparing the detected levels of adenosine, and metabolites thereof, with a standard curve to quantitate the amount of adenosine, and metabolites thereof, present in the biological sample. In other embodiment, step (i) is carried out under acidic conditions or with a mobile phase containing sodium perchlorate and acetonitrile at a pH in the range of 2 to 4. In a further embodiment, the adenosine metabolites include adenosine monophosphate, adenosine diphosphate, and adenosine triphosphate."

Robert Bosch GmbH

Patent Issued for Method for Determining the Predisposition of a Patient to Changed Biotransformation and to the Development of Undesired Drug Effects in a Treatment of the Patient with Atrovastatin (2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Robert Bosch GmbH (Stuttgart, DE) has been issued patent number
9528156, according to news reporting originating out of Alexandria, Virginia, by NewsRx editors.

The patent's inventors are Klein, Kathrin (Stuttgart, DE); Riedmaier, Stephan (Stuttgart, DE); Zanger, Ulrich (Korntal, DE).

This patent was filed on February 23, 2010 and was published online on December 27, 2016.

From the background information supplied by the inventors, news correspondents obtained the following quote: "Muscle diseases, such as for example myopathies and rhabdomyeloses, are diseases of the muscles which can for example be triggered by the administration of statins.

"Statins, which include the active substance atorvastatin, are medicinal substances which are 3-hydroxy-3-methylglutaryl coenzyme A reductase (HMG CoA reductase) inhibitors. HMG CoA in turn is an intermediate of human cholesterol synthesis, because of which statins are mainly used as cholesterol lowering agents in fat metabolism disorders. Here, through the inhibition of HMG CoA reductase, the statins effect a lipid lowering in the blood. Since HMG CoA is a substance involved in the biosynthesis of cholesterol, less cholesterol is formed in the body under the action of statins than without the administration of statins. Inter alia, examples of the statins include atorvastatin, cerivastatin, fluvastatin, lovastatin, pravastatin, rosuvastatin and simvastatin.

"Although statins are generally regarded as useful drugs, there are problems in the therapy, namely firstly as regards the uncertainty in the prediction of the effect corresponding to a certain dose, and secondly in the risk of the development of undesired drug effects (also abbreviated herein as ‘UDE’ and generally also described as side-effects).

"All statins, including atorvastatin, can cause undesired drug effects, among which the most severe are the so-called toxic myopathies, wherein there are structural and functional changes in the skeletal musculature. The most severe form of toxic myopathy is rhabdomyelosis, which inter alia manifest themselves in complete lamming of all four limbs and can often take a fatal course. Up to the year 2003, ca. 3350 cases of rhabdomyelosis triggered by lipid lowering agents had been described in the literature.

"Also, the strength of action of the various statins at present obtainable on the market is different; thus for example fluvastatin exhibits a low myopathy incidence, but on the other hand exhibits one of the weakest lipid lowering actions even at the maximum dosage.

"As further undesired drug effects during the use of statins such as atorvastatin, liver damage, a decline in memory performance and alertness, as well as increased aggressivity and increased irritability have been observed, as well as headache, nausea, anemia, nerve damage, hair loss, and the like.

"Since not all patients who are subjected to treatment with statins, in particular atorvastatin, for lowering the cholesterol content develop undesired drug effects, and patients react differently to certain statins, in particular atorvastatin, and the dosages thereof, it would be desirable to be able to determine, in advance of statin therapy, in particular atorvastatin therapy, the predisposition of a patient to develop undesired drug effects or to react other than as desired to the therapy."

Supplementing the background information on this patent, NewsRx reporters also obtained the inventors’ summary information for this patent: "The purpose of the present disclosure is therefore to provide a method for determining a predisposition of a patient for the development of undesired drug effects or for altered efficacy in a treatment of the patient with statins.

"According to the present disclosure, this problem is solved in that, in a biological
sample from the patient the presence of at least one single nucleotide polymorphism (SNP) in
the UGT1A3 gene (uridine diphosphate glucuronosyl transferase gene 1A3) and/or increased
UGT1A3 gene expression is determined.

"The problem on which the disclosure is based is fully solved in this manner.

"In their own experiments on the basis of the study of many human liver samples, the
inventors were able to show that genetic variations in the UGT1A3 gene led to increased
UGT1A3 gene expression. Further, the inventors were able to show that the increased gene
expression was accompanied by increased lactonization of the statin atorvastatin (ATV).

"An increased content of ATV lactone is found in atorvastatin patients who suffer
from a myopathy, and also increased concentrations of hydroxy metabolites of atorvastatin (see
Hermann et al., 'Exposure of atorvastatin is unchanged but lactone and acid metabolite are
increased several-fold in patients with atorvastatin-induced myopathy', Clin. Pharmacol. Ther.,
2006, 79: 532-539). Moreover, it has been demonstrated on a cell culture model that in
comparison to the respective statin acids, statin lactones exhibit 14-37 fold increased
myotoxicity (Skottheim et al., Statin induced myotoxicity: the lactone forms are more potent
than the acid forms in human skeletal muscle cells in vitro; Eur. J. Pharm. Sci. 33: 317-25
(2008)).

"It is known that in vivo atorvastatin is biotransformed inter alia into 2-(ortho) and 4-
(para) hydroxy ATV acids (pharmacologically active metabolites). Alternatively, the free acid
side-chain can be converted into cyclic ATV lactone. Owing to the higher lipophilicity of the
ATV lactone, this is hydroxylated much more readily than ATV itself (see Jacobsen et al., Drug
Metabol. Dispos. 28(11): 1369-78 (2000)). Thus with the present discoveries the inventors
were able for the first time to show that the increased content of ATV lactone and of hydroxy
ATV lactone is attributable to an increased activity of the enzyme uridine diphosphate
glucuronosyl transferase, or rather to the increased activity of the isoform 1A3 of this enzyme
triggered by the genetic variations.

"The ATV lactonization can admittely be catalyzed by several UGT isoforms (see
for example Goosen et al.: 'Atorvastatin glucoronidation is minimally and non-selectively
inhibited by the fibrates Gemfibrozil, Fenofibrate and Fenofibric Acid', Am. Soc. Clinic.
Pharma. Therap., 2007: 35(8) 1315-1323), however it was not previously known which of the
isoforms assumes the main function in vivo. As already stated, UGTs (UDP glucuronosyl
transferases) are enzymes which inter alia cause the lactonization of statins, for example
atorvastatin. In turn, compared to the statins themselves, the lactonized statins are preferentially
converted by the enzyme CYP3A into hydroxy-statins lactones.

"Herein, the UGT1A3 gene is always understood to mean the coding sequence of this
gene as well as the intron sequences and the 5`- and 3` untranslated/regulatory regions of the
gene.

"With the method now existing, it is for the first time possible to screen patients who
are to undergo a statin treatment, in particular an atorvastatin treatment, or patients who are
already undergoing a statin treatment, so as to determine whether they are genetically
predisposed to increased activity of the isozyme UGT1A3, and thereby run the risk of forming
more statin lactone and hydroxy statin lactone, which can lead to the abovementioned muscle
diseases, or to a partial failure of therapy, since the statin lactones are pharmacologically
inactive metabolites. Thus in this case or in these patients, atorvastatin very probably does not
possess the same activity as is the case in patients who do not exhibit these polymorphisms.
Advantageously, by the determination of the polymorphisms it can then directly be predicted
whether atorvastatin is biotransformed to an increased extent and will thus be less effective at its
dosage than in a patient who does not exhibit the polymorphisms; if polymorphisms according
to the present disclosure are identified, either the actual or planned dosage of atorvastatin can be appropriately adapted, i.e. increased, in order to achieve a similar activity of atorvastatin as in wild type patients, or recourse can be had to another statin or another therapeutic approach in order to avoid undesired drug effects.

"According to the present disclosure, this is effected by the determination of at least one SNP in the UGT1A3 gene. Thereby, the therapy of the patient to be treated with the statin can be individually tailored, i.e. either entirely different alternatives to the statins can be used, or else the dosage and hence the efficacy of certain statins to be administered can be individually considered for the patient.

"As well as atorvastatin, other statins are at present also used, such as for example cerivastatin, fluvastatin, lovastatin, pravastatin, rosuvastatin and simvastatin.

"Said statins are at present sold on the market for example under the names Sortis.RTM., Lipitor.RTM. (atorvastatin), Baycol.RTM., Zenas.RTM. (cerivastatin), Cranoc.RTM., Lescol.RTM., Locol.RTM., Fractal.RTM. (fluvastatin), Mevinacor.RTM. (lovastatin), Mevalotin.RTM., Pravasin.RTM., Pravachol.RTM. (pravastatin), Crestor.RTM. (rosuvastatin), Gerossim.RTM., Simvabeta.RTM., Zocor.RTM. (simvastatin) and the corresponding generic forms thereof.

"With the method now available, a targeted and individualized cholesterol synthesis inhibitor therapy can now advantageously be provided whereby the patients who have to undergo such a therapy can be examined for the presence of SNPs in the UGT1A3 gene either before or during the treatment with one of said drugs. If an SNP which leads to increased expression of this gene and hence to increased activity of the UDP glucuronyl transferase is present, the treatment can be performed or continued either with alternatives to the statins or with a statin other than that intended, or else with a dosage other than the original one or that originally intended.

"In a further embodiment, it is preferred if at least one of the following haplotypes is determined in the method according to the disclosure: UGT1A3*2, UGT1A3*3, UGT1A3*6 and in particular one of the following SNPs in the UGT1A3 gene:

"UGT1A3*2: rs55772651, rs1983023, rs6304713, rs45507691, rs3806597, rs3806596, rs3821242, rs6706232, rs6431625, rs1786836 and rs7574296;

"UGT1A3*3: rs55772651, rs6304713, rs3806597, rs3806596, rs3821242, rs6706232 and rs7574296;

"UGT1A3*6: rs55772651, rs1983023, rs6304713, rs3806597, rs3806596, rs3821242, rs6706232, rs6431625, rs7574296 and rs45449995.

"Herein the expression 'genomic Pos. in AF297093' is used to designate an SNP for which no rs number is available, the position whereof in the UGT1 gene locus which is designated with the access number AF297093 according to the publicly accessible databases is correspondingly stated (on the UGT1 gene locus see for example the EMBL EBI database under http://www.ebi.ac.uk/cgi-bin/expasyfetch?AF297093 or the database GenBank of the National Center for Biotechnology Information NCBI http://www.ncbi.nlm.nih.gov/).

"SNPs (single nucleotide polymorphisms) designate variations of individual base pairs in a DNA strand compared to the wild type in a certain population. SNPs represent ca. 90% of all genetic variants in the human genome, and occur unequally strongly in certain regions in the genome. They are mutations, i.e. genetic changes, which have to a certain extent become established in the gene pool of a population. Also, the SNPs can occur as substitutions, in which a base, for example cytosine, is replaced by another base, for example thymine, or else as deletions or insertions.

"Here, SNPs always have one of two or very rarely also several states and are
allelically transmitted. The majority of the known SNPs affect non-coding regions in the genome, i.e. regions which lie either between genes or between exon regions of individual genes. In principle, these gene variants in non-coding regions can also affect regulatory sequences, e.g. promoters, enhancers or splicing sites and hence have effects on the expression of genes. SNPs which directly affect the coding sequence can be silent, i.e. the base substitution does not alter the translation of the corresponding triplet code into the analogous amino acid and hence thereby has no influence on the peptide sequence. However, because of different frequency of equivalent t-RNAs for specific base triplets, differences for the efficiency of the translation can arise and thus the expression of certain genes can be influenced post-transcriptionally by silent SNPs. Some SNPs have a coding function, i.e. the different alleles lead to the incorporation of a different amino acid into the resulting peptide, with the result that the function thereof can be changed.

"In the genome, if they are present biallelically, SNPs can occur in three possible genotypes, namely in one of two homozygotic forms (allele 1/allele 1 or allele 2/allele 2) or else in one heterozygotic form (allele 1/allele 2). Adjacent SNPs can be linked together to a varying extent. That is, up to a certain percentage they arise in the population in a certain combination only together and thus form a so-called haplotype. Here, 'coupling' is understood to mean the tendency that the alleles present each time at two different positions on one chromosome are passed on together (on the same chromosome), i.e. are transmitted coupled. In general here, with alleles that tend to be transmitted together the term 'linkage disequilibrium' is used.

"Since genomic DNA is double-stranded, each SNP can be identified with reference to each of the two strands. The SNPs preferred in the present application admittedly contain one substitution of one nucleotide by another at the polymorphic sites of the SNP, but SNPs can also be more complex and can have a deletion of a nucleotide from one, or an insertion of a nucleotide into, one of two corresponding sequences.

"The expression 'determine' as it is used herein for the determination of the SNPs, relates to various methods and processes for the analysis of one or more SNP at a certain site in the genome, and the expression also includes both direct determination, i.e. for example sequencing, and also indirect determination, i.e. for example amplification and/or hybridization.

"The inventors have now discovered that, surprisingly, it is possible on the basis of certain SNPs in the UGT1A3 gene to diagnose a genetic predisposition for the development of muscle diseases or a changed efficacy in the administration of statins.

"With the new method, it is now for the first time possible to prognosticate an individually probable exacerbation of a muscle disease on administration of atorvastatin or an individually probable lowered efficacy of atorvastatin.

"Also, in a further embodiment it is preferred if the at least one SNP is selected from the SNPs which are in linkage disequilibrium with the SNPs of the UGT1A3*2, UGT1A3*3 and UGT1A3*6 haplotypes.

"This means that in the context of the method according to the disclosure SNPs can also be detected which can likewise be used as markers of the haplotypes of the UGT1A3*2, UGT1A3*3 and UGT1A3*6, but are not explicitly listed here, but which are in linkage disequilibrium with the aforesaid SNPs (see for example Menard V. et al., 'Analysis of inherited genetic variations at the UGT1 locus in the French-Canadian population'. Hum Mutat. 2009 Feb. 8).

"In a further embodiment of the method according to the disclosure, it is preferred if the increased UGT1A3 gene expression is determined via an increased mRNA level and/or an increased protein level.

"The proof provided by the inventors that the genetic variations in the UGT1A3 gene
lead to increased UGT1A3 expression and hence also to increased activity of this enzyme is contrary to the knowledge previously obtained, albeit only by means of recombinant isoenzymes, according to which the genetic variations were as a rule associated with decreased function (see for example Chen et al., 'Genetic Variants of Human UGT1A3: Functional Characterization and Frequency Distribution in a Chinese Han Population', Drug Metabolism and Disposition, 2006, 34: 1462-1467; Caillier et al., 'A pharmacogenomics study of the human estrogen glucuronosyl transferase UGT1A3', Pharmacogenet. Genomics 2007, 17(7): 481-95).

"Hence the present discoveries and the method provided, although admittedly UGT1A3 and UGT1A3 polymorphisms were already identified in the state of the art, are novel and surprising, since the polymorphisms were associated with decreased activity or expression of UGT1A3. However the inventors of the present application have now precisely found out that the polymorphisms are accompanied by higher UGT1A3 expression and as a result also increased activity, which, as described further above, leads to the increased ATV lactonization.

"In particular in the process according to the disclosure it is preferred if for the detection of at least one SNP in the UGT1A3 gene an oligonucleotide is used which is selected from one of the oligonucleotides listed in Tables 1 and 2, or from the oligonucleotides with the SEQ ID Nos. 1 to 27:

"TABLE-US-00001 TABLE 1 UGT1A3 amplification primers. Ampl. SEQ-ID Genomic product No. position Primer sequence (5'.fw darw. 3') (bp) 1 144852-145219 ACGTTGGATGCTCTGGATGACTGAATTAAG 388 2 ACGTTGGATGCACTTGGAGGCTGGCTATG 3 145477-145927 ACGTTGGATGACTTGGATGTTCCCCAGAGT 471 4 ACGTTGGATGCTCTGGGGTGAGGACCACT 5 145934-146495 ACGTTGGATGACTTTGAGTCTCCACAGAGT 582 6 ACGTTGGATGACAGATGCATGACTGAGAAT 7 146519-146741 ACGTTGGATGCTCTGGGGTGAGGACCACT 5 145934-146495 ACGTTGGATGACTTTGAGTCTCCACAGAGT 582 6

"Here, the oligonucleotides with the SEQ ID Nos. 1, 3, 5 and 7 are forward ('f') primers and the oligonucleotides with the SEQ ID Nos. 2, 4, 6 and 8 reverse ('r') primers.

"TABLE-US-00002 TABLE 2 Extension primers for the MALDI-TOF mass spectrometric analysis SEQ-ID Genomic Mass of the ampl. No. Assay position Primer sequence (5'.fw darw. 3') product (Da) 9 1 144977 CTCCCTGAAACCCTACAGCA 5411.4 11 1 145154 GGATATTTCTTGTAAGGATCA 6475.2 12 3 145182 TGGGTGTTGTGTTTTTTT 5219.4 13 1 145531 CCTGGAAAGACCGATCA 5501.6 14 1 145669 TGCTACATTTGTCTTCTTC 5710.7 15 3 145765 CTGAGATGCCCAGAGATGCTCCAGCC 4858.2 17 1 145815 ACCAAACACTCTTACT 5034.3 18 2 145874 GCACTGGAGCTCCGCAAG 5509.6 19 2 145968 ACGAAATGCGTGGAGGAA 5459.3 20 3 146062 ATTTGGCTACCTTCTGCG 5501.6 1 146076 GACATATTTGCTCAACAGTCCTGCCTC 5770.8 21 1 146207 CCCTGAACTTTCTCAGCGATCA 6091.0 22 3 146207 GCGGCGCTCTTCTCAGCGATCA 6801.9 23 1 146253 GATTCCTACCTTTCTCTCTC 6374.2 24 1 146253 GATTCCTACCTTTCTCTCTC 6374.2 25 1 146271 AGAACATTTCCCATGTA 5218.4 26 1 146356 CACCAATTCAGACCACATGACATTC 7852.1 27 1 146542 TACCCAGGCAATC 4481.9

"Genomic (gen.) position corresponding to the file with the GenBank access number (Acc. Number) AF297093.1.

"With these oligonucleotides, the inventors were successfully able to amplify the regions containing the SNPs and to identify the SNPs via the extension of these oligonucleotides
(primers). Hence the present disclosure also relates to these oligonucleotides themselves.

"In a further embodiment it is preferred if at least one of the following methods is used for the determination of the at least one SNP: PCR-based methods, DNA sequencing methods, hybridization methods, mass spectroscopy, HPLC methods and primer extension methods.

"These methods are adequately known in the state of the art and are already used for the identification of SNPs. For example reference is hereby made to 'Guide to Mutation Detection' by Graham R. Taylor and Ian N. M. Day (Wiley & Sons, 2005) in which these methods are adequately described.

"In a further embodiment it is preferred if the following PCR cycles are used for the amplification of the SNP containing regions.

"Denaturation at ca. 95°. C. for 15 mins, followed by 5 cycles with the steps ca. 95°. C. for 20 secs, ca. 65°. C. for 30 secs and ca. 72°. C. for 1 min; followed by 40 cycles with the steps ca. 95°. C. for 20 secs, ca. 62°. C. for 30 secs and ca. 72°. C. for 1 min, followed by a final extension step at ca. 72°. C. for 10 mins.

"Further, the disclosure also relates to diagnostic kits for the determination of a predisposition of a patient for the development of muscle diseases in a treatment of the patient with statins, wherein the kit contains at least one oligonucleotide as described above.

"With the kit according to the disclosure a simple tool is provided with which at least one relevant SNP in the UGT1A3 gene and can be rapidly detected, whereby patients can be identified who will with high probability develop muscle diseases as a side-effect during a therapy with a statin.

"The disclosure further relates to the use of at least one SNP in the human UGT1A3 gene, in particular the SNPs rs55772651, rs1983023, rs56304713, rs45507691, rs3806597, Rs3806596, rs3821242, rs6706232, rs6431625, rs17868336, rs7574296, g.146356 (gen. Pos. In Af297093) and rs45449995 and also other SNPs which are in linkage disequilibrium with the UGT1A3*2, UGT1A3*3 and UGT1A3*6 haplotypes for the determination of the predisposition of a patient to the development of muscle diseases during the treatment of statins.

"Further advantages and features of the disclosure emerge from the following description and the attached diagrams.

"It goes without saying that the features stated above and features yet to be explained below are usable not only in the combination stated in each case, but also in other combinations or alone, without departing from the scope of the present disclosure."

Patent Issued for Method for Diagnosing Glaucoma by Observing Connective Tissue of Lamina Cribrosa (USPTO 9526414)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Yoneya; Shin (Maebashi-Shi, JP) has been issued patent number 9526414, according to news reporting originating out of Alexandria, Virginia, by NewsRx editors.

The patent's inventor is Yoneya, Shin (Maebashi, JP).

This patent was filed on May 23, 2014 and was published online on December 27, 2016.

From the background information supplied by the inventors, news correspondents obtained the following quote: "In the past, glaucoma was regarded as a disease causing characteristic optic nerve disablement (optic nerve damage) due to ocular hypertension. However, an epidemiological research ('the Tajimi study') conducted from 2000 to 2001 has revealed that the prevalence rate of normal-tension glaucoma (normotensive glaucoma) is significantly higher than that of hypertension glaucoma (high-tension glaucoma) in Japan compared with the Western countries. At present, glaucoma is defined as 'a disease that involves distinctive changes in optic disc and the visual field and is marked by functional and structural abnormalities (disorders) in the eye in which optic nerve damage can ordinarily be alleviated and inhibited by sufficiently reducing intra-ocular pressure' (the Japan Glaucoma Society Guidelines for Glaucoma (3rd Edition)). Therefore, at present, the main purpose of glaucoma treatment is to reduce intra-ocular pressure. In addition, there have been attempts to develop neuroprotective agents in recent years. However, treatment of glaucoma involving the reduction of intra-ocular pressure has limitations. Thus, glaucoma is the leading disease in terms of the certification of physical disability caused by visual impairment in Japan.

"Regarding glaucoma in the Western countries, the prevalence rate of high-tension glaucoma has been higher than that of normal-tension glaucoma and thus there has been little attention to normal-tension glaucoma. In the history of glaucoma, the possibility of the presence of normal-tension glaucoma was suggested. For example, 'Duke-Elder's System of Ophthalmology' published in 1969 recites as follows: 'It is to be remembered that an intra-ocular pressure that is generally accepted as being within the normal range may produce the typically pathological effects at the optic disc and in the visual fields when the nerve head is unduly vulnerable and may occur, for example, in myopic eyes; these cases properly come under the definition of glaucoma.' It is suggested that the reason for the high prevalence rate of normal-tension glaucoma in Japan is associated with myopia. However, there has been no specific explanation why optic disc is 'fragile' in patients with myopia.

"Optic Nerve Structure and Optic Disc Structure

"Light enters into the eye and then is received by visual cells (the first neurons) so as to be converted into signals. The signals are further transmitted from bipolar cells (the second neurons) to ganglion cells. Axis cylinders of the ganglion cells serve as optic nerve fibers (the third neurons). The optic nerve fibers form a fascicle and the fascicle extends from optic disc outside the eye for signal transmission to the visual center of the brain.

"Optic disc has a relatively oblong elliptical shape with a diameter of about 1.6 mm and is positioned on the nasal side of macula lutea (limbus luteus).
Cylinders of ganglion cells form a fascicle of optic nerve fibers such that the fascicle extends outside the eye. In addition, the central retinal artery and vein also extend through optic disc. When the fascicle of optic nerve fibers extends outside the eye, the optic nerve fibers run through 500-600 lamina pores of lamina cribrosa formed with connective tissue. When viewed from the exterior of the eye, the optic nerve is positioned on the nasal side of the eyeball in a horizontal view.

"FIG. 2 shows a general image of a fascicle of optic nerve fibers extending through lamina cribrosa obtained by histological examination or scanning microscopic observation. However, there has been no literature about the anatomical role of lamina cribrosa as well as the morphological details thereof."

Supplementing the background information on this patent, NewsRx reporters also obtained the inventor's summary information for this patent: "The inventors of this invention developed femto second mode-lock type optical coherence tomography (OCT) using a laser as a light source, which is disclosed in Suzuki M, Baba M, Yoneya S and Kuroda H. Efficient special broadening of Supercontinuum in photonic crystal fiber with self-phase modulation induced by femtosecond laser pulse, Applied Physics Letters 101. 191110 (2012). The present inventors further succeeded in three-dimensionally observing lamina cribrosa of the living eye by the OCT. Accordingly, the present inventors elucidated the mechanism of the onset of glaucoma by comparing normal eyes and glaucoma eyes and revealed that changes in connective tissue of lamina cribrosa caused by aging of optic disc and continuous mechanical stimulation are associated with the primary lesion of glaucoma. The above findings have led to the completion of the present invention.

"The present invention relates to a method for diagnosing the primary lesion of glaucoma by observing lamina cribrosa to determine the degree of movability of the lamina cribrosa with respect to the retina surface."

Ghost Medical Technologies, Ltd.

**Patent Issued for Method for Non-Contrast Enhanced Magnetic Resonance Angiography (USPTO 9526423)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Ghost Medical Technologies, Ltd. (Highland Park, IL) has been issued patent number 9526423, according to news reporting originating out of Alexandria, Virginia, by NewsRx editors.

The patent's inventor is Edelman, Robert (Highland Park, IL).
This patent was filed on May 25, 2016 and was published online on December 27, 2016.

From the background information supplied by the inventors, news correspondents obtained the following quote: "The field of the invention is magnetic resonance imaging (‘MRI’) and systems. More particularly, the invention relates to methods for non-contrast enhanced magnetic resonance angiography (‘MRA’).

"When a substance such as human tissue is subjected to a uniform magnetic field (polarizing field B\textsubscript{0}), the individual magnetic moments of the nuclei in the tissue attempt to align with this polarizing field, but precess about it in random order at their characteristic Larmor frequency. If the substance, or tissue, is subjected to a magnetic field (excitation field B\textsubscript{1}) that is in the x-y plane and that is near the Larmor frequency, the net aligned moment, M\textsubscript{z}, may be rotated, or 'tipped', into the x-y plane to produce a net transverse magnetic moment M\textsubscript{xy}. A signal is emitted by the excited nuclei or 'spins', after the excitation signal B\textsubscript{1} is terminated, and this signal may be received and processed to form an image.

"When utilizing these ‘MR’ signals to produce images, magnetic field gradients (G\textsubscript{x}, G\textsubscript{y}, and G\textsubscript{z}) are employed. Typically, the region to be imaged is scanned by a sequence of measurement cycles in which these gradients vary according to the particular localization method being used. The resulting set of received MR signals are digitized and processed to reconstruct the image using one of many well known reconstruction techniques.

"The measurement cycle used to acquire each MR signal is performed under the direction of a pulse sequence produced by a pulse sequencer. Clinically available MRI systems store a library of such pulse sequences that can be prescribed to meet the needs of many different clinical applications. Research MRI systems include a library of clinically proven pulse sequences and they also enable the development of new pulse sequences.

"Magnetic resonance angiography (‘MRA’) uses the magnetic resonance phenomenon to produce images of the human vasculature. To enhance the diagnostic capability of MRA, a contrast agent such as gadolinium can be injected into the patient prior to the MRA scan. The trick with this contrast enhanced (‘CE’) MRA method is to acquire the central k-space views at the moment the bolus of contrast agent is flowing through the vasculature of interest. Collection of the central lines of k-space during peak arterial enhancement, therefore, is key to the success of a CE-MRA exam. If the central lines of k-space are acquired prior to the arrival of contrast, severe image artifacts can limit the diagnostic information in the image. Alternatively, arterial images acquired after the passage of the peak arterial contrast are sometimes obscured by the enhancement of veins. In many anatomic regions, such as the carotid or renal arteries, the separation between arterial and venous enhancement can be as short as 6 seconds.

"The short separation time between arterial and venous enhancement dictates the use of acquisition sequences of either low spatial resolution or very short repetition times (‘TR’). Short TR acquisition sequences severely limit the signal-to-noise ratio (‘SNR’) of the acquired images relative to those exams in which a longer TR is employed. The rapid acquisitions required by first pass CE-MRA methods thus impose an upper limit on either spatial or temporal resolution.

"Recently, a rare and serious pathology involving fibrosis of skin, joints, eyes, and internal organs referred to as nephrogenic systemic fibrosis (‘NSF’) has been correlated to the administration of gadolinium-based contrast agents to patients undergoing contrast-enhanced MRA studies. The link between gadolinium-based contrast agents and NSF is described, for example, by P. Marckmann, et al., in 'Nephrogenic Systemic Fibrosis: Suspected Causative Role of Gadodiamide Used for Contrast-Enhanced Magnetic Resonance Imaging,' J. Am. Soc. Nephrol., 2006; 17 (9):2359-2362. As a result of the increased incidence of NSF, methods for
MRA that do not rely on the administration of a contrast agent to the patient have become an important field of research. However, current methods for non-contrast angiography are limited in their utility because they are sensitive to patient motion, do not consistently or accurately portray vessel anatomy in patients with severe vascular disease, and require excessively long scan times.

"While single shot acquisition methods such as two-dimensional ('2D') balanced steady-state free precession ('bSSFP') have the potential to reduce motion artifacts and shorten exam times, arterial conspicuity is inadequate due to high background signal. Moreover, bSSFP methods do not lend themselves to the creation of maximum intensity projection ('MIP') angiograms. In one example, a saturation-recovery bSSFP pulse sequence employed for cardiac perfusion imaging following the administration of a paramagnetic contrast agent is described by W. G. Schreiber, et al., in 'Dynamic Contrast-Enhanced Myocardial Perfusion Imaging Using Saturation-Prepared TrueFISP,' JMRI, 2002; 16:641-652. However, this pulse sequence applies a spatially non-selective saturation pulse that suppresses the signal from blood and, thus, cannot be employed for MRA. Additionally, Schreiber's method does not provide a means for distinguishing arteries from veins.

"It is, in fact, particularly challenging to suppress venous signal with a single shot acquisition since, unlike arterial blood, venous blood typically flows slowly or even, for periods of time, not at all. In addition, the venous flow pattern is largely unpredictable, sometimes varying with a patient's respiration cycle, cardiac cycle, or both. Consequently, it is problematic to eliminate the signals from veins with single shot acquisitions, since venous blood flows only a short distance or not at all during the short scan time. Unfortunately, venous signals tend to overlap with arterial signals on projection images, thereby making it difficult or impossible to diagnose arterial disease using such methods for MRA. In addition, a robust single shot non-contrast MRA technique must provide an accurate depiction of arterial anatomy over a wide range of flow velocities, ranging from a few centimeters per second ('cm/sec') to more than 100 cm/sec. Moreover, the arterial anatomy must be depicted with sufficient arterial conspicuity to allow creation of a projection angiogram.

"Several approaches have been previously described to suppress venous signal on non-contrast MR angiograms as follows. One method for venous suppression has been accomplished using image subtraction. Techniques like fresh blood imaging ('FBI') involve the subtraction of two images with different arterial signals, but identical venous signals. In this manner, the venous, but not arterial, signals cancel with subtraction. Unlike the saturation-based methods, subtraction techniques eliminate the signals from both stationary and moving venous spins. However, image subtraction doubles scan time and greatly increases the sensitivity of the technique to patient motion. In addition, these methods require prior knowledge of flow velocities in order to maximize arterial conspicuity.

"Another method for suppressing venous signals is to employ a T.sub.2-weighted magnetization preparation pulse, which diminishes signal in veins since venous blood has a reduced oxygen tension. However, this method is inconsistently effective since the level of venous oxygenation varies widely and unpredictably.

"Yet another method is to repeatedly apply a saturation radio frequency ('RF') pulse just prior to the pulse sequence used for data acquisition, and to repeat this process multiple times at typical intervals of 20-200 milliseconds ('ms'). However, the use of a single shot acquisition with subsecond data acquisition time does not afford the time to repeatedly apply a saturation RF pulse. As a result, this approach is only applicable to multi-shot acquisition techniques where the data is acquired over tens of seconds to several minutes. Moreover, the repeated application of RF pulses causes marked suppression of arterial signal in tortuous
vessels, thereby limiting the diagnostic accuracy of these methods.

"A single shot acquisition method for MRA is described by R. Edelman, et al., in 'Fast Time-of-Flight MR Angiography with Improved Background Suppression,' Radiology, 1991; 179:867-870. This method requires the use of an inversion recovery preparation pulse and relies on arterial inflow during the data acquisition period to produce arterial contrast. In this respect, the inversion time ('TI') is selected solely to match the center lines of k-space to the 'null' point for the longitudinal magnetization of background tissue, and is not selected in order to allow for the inflow of arterial blood into the imaging slice. In other words, the purpose of the TI is to reduce the signal intensity of background tissues.

"This method suffers from several drawbacks. For example, the method acquires data over a lengthy time period on the order of one second, thereby encompassing both systole and diastole. With this lengthy time period required for data acquisition, it is not possible to synchronize TI to the period of rapid, systolic arterial flow, nor to the period of slow diastolic flow. Moreover, the TI employed by Edelman is too short (on the order of 75 ms) to allow for substantial arterial inflow. As a result, most of the arterial inflow occurs during the application of repeated RF pulses. As described above, the repeated application of RF pulses in this manner causes marked suppression of arterial signal in tortuous vessels, thereby limiting the diagnostic accuracy of such methods for MRA. The method also does not allow for the effective suppression of venous or fat signals, which are both essential to accurately depict the arteries.

"Other methods of non-contrast enhanced MRA are described, for example, by M. Katoh, et al., in 'Free-Breathing Renal MR Angiography With Steady-State Free-Precession (SSFP) and Slab-Selective Spin Inversion: Initial Results,' Kidney International, 2004; 66:1272-1278, and by Y. Yamashita, et al., in 'Selective Visualization of Renal Artery Using SSFP with Time-Spatial Labeling Inversion Pulse: Non-Contrast Enhanced MRA for Patients with Renal Failure,' Proc. Intl. Soc. Mag. Reson. Med. 13 (2005) p. 1715. The method described by Katoh utilizes a three-dimensional ('3D') acquisition with a pre-inversion of the 3D region, while Yamashita employs two inversion pulses (one spatially selective and the other spatially non-selective). Each of these methods uses inversion preparation pulses rather than saturation pulses and further requires the use of a 3D, rather than 2D, acquisition for MRA. Given the substantial thickness of the 3D imaging slab, inflowing unsaturated spins must travel a large distance (for example, up to several centimeters) to replace in-plane saturated ones. Consequently, there is poor depiction of slowly flowing arterial spins. In fact, the inversion time, TI, must be very long (on the order of 1 second) to provide adequate inflow of even moderately fast flowing arterial spins. The long TI spans both the systolic and diastolic phases of the cardiac cycle. Given the long TI, it is problematic to synchronize data acquisition to diastole. In addition, 3D acquisitions are too time-consuming to permit data acquisition within a single breath-holding period.

"A 2D adaptation of Yamashita's 'time-SLIP' acquisition is described by S. Yamada, et al., in 'Visualization of Cerebrospinal Fluid Movement with Spin Labeling at MR Imaging: Preliminary Results in Normal and Pathophysiologic Conditions,' Radiology, 2008; 249:644-652. This method, however, is employed to image the flow of cerebrospinal fluid flow rather than for MRA applications. Additionally, it uses two inversion pulses, rather than saturation pulses, and has a very long TI (on the order of 2500 ms) that is incompatible with MRA studies.

"It would therefore be desirable to provide a method for non-contrast enhanced MRA that produced images of a patient's vasculature in a relatively short duration of time while maintaining significant discrimination of the arteries and substantially suppressing venous signals. Moreover, it would be desirable to provide a method for non-contrast enhanced MRA that was insensitive to flow velocities and was relatively insensitive to patient motion and other
imaging artifacts."

Supplementing the background information on this patent, NewsRx reporters also obtained the inventor's summary information for this patent: "The present invention overcomes the aforementioned drawbacks by providing a method for non-contrast enhanced magnetic resonance angiography (MRA) that has a short scan time and is insensitive to patient motion, while maintaining significant arterial conspicuity and substantial venous signal suppression. This is achieved by employing a two-dimensional ('2D') single shot acquisition.

"It is an aspect of the invention to provide a method for non-contrast enhanced MRA that is substantially insensitive to variations in arterial flow velocity or heart rate and that further substantially suppresses unwanted venous signal in a prescribed 2D imaging slice. A method for accurately depicting normal and diseased arteries despite a wide range of flow velocities is provided by synchronizing a quiescent interval ('QI') to the period of rapid, systolic arterial blood flow so as to maximize flow-related enhancement into the imaging slice. Additionally, this method is provided by synchronizing data acquisition to occur during diastole when arterial blood is stationary or flowing relatively slowly into a prescribed imaging slice. If venous blood flow is flowing in a cranial direction and arterial blood flow in a caudal direction, as is the case for the peripheral arteries, this venous suppression can be further augmented by the application of saturation pulses prior to the QI. The saturation pulses are applied not only in the imaging slice, but also in a slab contiguous with and caudal to the imaging slice. Likewise, when venous blood flow is flowing in a cranial direction and arterial blood in the cranial direction, as is the case in the internal jugular vein and common carotid artery, respectively, the slab is selected to be contiguous with and cranial to the imaging slice. In this manner, saturated venous spins and unsaturated arterial spins will flow into the imaging slice over the duration of the QI. Such a method differs fundamentally from previously described methods for suppressing venous signal since, in prior methods, saturation pulses were applied directly before the radio frequency ('RF') excitation, allowing negligible time for inflow of saturated venous spins into the imaging slice."

"It is another aspect of the invention to provide a method for non-contrast enhanced MRA that can produce images in a relatively short duration of time. For example, the entire length of the peripheral arteries can be imaged in 8 minutes with high arterial conspicuity and marked suppression of venous signal. Since the method uses a single shot acquisition, no ghost artifacts occur and the method is highly resistant to motion artifact. Previously described MRA techniques, including fresh blood imaging and 2D time of flight, do not use a single shot acquisition and thus are prone to motion artifacts and longer scan times. Additionally, the shortened scan time required with the method of the present invention allows for a series of 2D images to be obtained within a single breath-hold.

"The foregoing and other aspects and advantages of the invention will appear from the following description. In the description, reference is made to the accompanying drawings which form a part hereof, and in which there is shown by way of illustration a preferred embodiment of the invention. Such embodiment does not necessarily represent the full scope of the invention, however, and reference is made therefore to the claims and herein for interpreting the scope of the invention."

Patent Issued for Method for Producing Heterogeneous Catalysts Containing Metal Nanoparticles (USPTO 9527068)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A patent by the inventors Jia, Jifei (El Cerrito, CA); Wang, Jian (San Mateo, CA); Fujdala, Kyle L. (San Jose, CA), filed on April 1, 2013, was published online on December 27, 2016, according to news reporting originating from Alexandria, Virginia, by NewsRx correspondents.

Patent number 9527068 is assigned to Shubin, Inc. (Los Altos, CA).

The following quote was obtained by the news editors from the background information supplied by the inventors: "Field of the Invention"

"The present invention generally relates to the production of supported catalysts, and more particularly, to a method for making a heterogeneous catalyst containing metal nanoparticles dispersed throughout the support material for the heterogeneous catalyst.

"Description of the Related Art"

"Many industrial products such as fuels, lubricants, polymers, fibers, drugs, and other chemicals would not be manufacturable without the use of catalysts. Catalysts are also essential for the reduction of pollutants, particularly air pollutants created during the production of energy and by automobiles. Many industrial catalysts are composed of a high surface area support material upon which chemically active metal nanoparticles (i.e., nanometer sized metal particles) are dispersed. The support materials are generally inert, ceramic type materials having surface areas on the order of hundreds of square meters/gram. This high specific surface area usually requires a complex internal pore system. The metal nanoparticles are deposited on the support and dispersed throughout this internal pore system, and are generally between 1 and 100 nanometers in size.

"Processes for making supported catalysts go back many years. One such process for making platinum catalysts, for example, involves the contacting of a support material such as alumina with a metal salt solution such as chloroplatinic acid. The salt solution 'impregnates' or fills the pores of the support during this process. Following the impregnation, the support containing the salt solution would be air dried, causing the metal salt to precipitate within the pores. The support containing the crystallized metal salt would then be exposed to a hydrogen or carbon monoxide gas environment, reducing the solid metal salt to metal particles.

"Another process for making supported catalysts involves the steps of contacting a support material with a metal salt solution and reducing the metal ions to metal particles in situ using suitable reducing agents. The following are examples of this process. U.K. Patent No. 1,282,138 teaches methods for preparing metal catalysts using different reducing agents, including glucose, hydroxylamine hydrochloride, and hydrazine. U.S. Pat. No. 4,086,275 teaches methods for preparing copper catalysts using sodium borohydride as the in situ reducing agent. U.S. Pat. No. 4,835,131 teaches methods for preparing molybdenum on silica catalyst, copper on gamma-alumina catalyst, silver on silica catalyst and silver on gamma-alumina catalyst. The reducing agents used to prepare these catalysts include hydrazine, ammonium..."
hydroxide, and formaldehyde. U.S. Pat. Nos. 5,275,998 and 5,275,999 teach methods for preparing metal catalysts on carbon support and on alumina support using different reducing agents, including hydrazine hydrate, ascorbic acid, and sodium borohydride. According to these patents, supported catalysts having very small metal particle size (average size not greater than 2 nanometers) can be produced if the preparation steps are carried out in the presence of ethylene and/or acetylene (U.S. Pat. No. 5,275,998) or in the presence of carbon monoxide (U.S. Pat. No. 5,275,998). U.S. Pat. No. 6,686,308 teaches methods for preparing metal catalysts on silica using sodium citrate or potassium citrate as the reducing agent. This patent also teaches the use of colloid stabilizers including sodium sulfanilate, and discloses that it is preferable to use colloid stabilizers that can also act as reducing agents, namely ammonium citrate, potassium citrate, and sodium citrate.

In addition to the background information obtained for this patent, NewsRx journalists also obtained the inventors’ summary information for this patent: "The present invention provides additional methods for preparing supported metal catalysts. According to an embodiment of the present invention, a monomer is added to a solvent containing metal salt and porous support materials and the solvent is stirred for a period of time to precipitate and/or reduce the metal salt in the pores of the support materials. The solids that are dispersed in the solvent are then separated from the liquid, dried and calcined to form the supported catalyst. The monomer that is added to the solvent is of a type that can be polymerized in the solvent to form oligomers or polymers, or both. Acrylic acid may be used as such a monomer.

"According to another embodiment of the present invention, a supported catalyst is prepared by first forming an interim supported metal catalyst through reduction or precipitation, and then carrying out the further steps of mixing the interim supported metal catalyst and metal salt of the same metal type in a solvent, adding a fixing agent to the solvent and stirring the solvent to precipitate or reduce the metal salt in the pores of the support materials for the catalyst, separating out the solid in the solvent, drying the separated solid, and calcining it. The fixing agent for causing the reduction or precipitation during the process for forming the interim supported metal catalyst is selected based on the particular metal-support combination being used. Likewise, the fixing agent that is added to the solvent is selected based on the particular metal-support combination being used.

"According to still another embodiment of the present invention, a supported catalyst is prepared by first forming an interim supported metal catalyst through reduction or precipitation, and then carrying out the further steps of mixing the interim supported metal catalyst and metal salt of a different metal type in a solvent, adding a fixing agent to the solvent, stirring the solvent, separating out the solid in the solvent, drying the separated solid, and calcining it. At least one of the fixing agents for causing the reduction or precipitation during the process for forming the interim supported metal catalyst and the fixing agent that is added to the solvent is a monomer of a type that can be polymerized in the solvent to form oligomers or polymers, or both. Acrylic acid may be used as such a monomer."

Nuvectra Corporation

Patent Issued for Method of Making a Braided Lead with Imbedded Fixation Structures (USPTO 9526887)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Nuvectra Corporation (Plano, TX) has been issued patent number 9526887, according to news reporting originating out of Alexandria, Virginia, by NewsRx editors.

The patent's inventors are Finley, James (St. Anthony, MN); Swoyer, John M. (Blaine, MN).

This patent was filed on January 23, 2014 and was published online on December 27, 2016.

From the background information supplied by the inventors, news correspondents obtained the following quote: "Implantable medical electronics devices consist of an implanted pulse generator that is used to provide electrical stimulation to certain tissues and an implantable lead or leads that are used to transmit the electrical impulse to the targeted tissues. Examples include cardiac pacemaking, and a number of related applications for cardiac rhythm management, treatments for congestive heart failure, and implanted defibrillators. Other applications for implantable pulse generators include neurostimulation with a wide range of uses such as pain control, nervous tremor mitigation, incontinent treatment, epilepsy seizure reduction, vagus nerve stimulation for clinical depression, and the like.

"Despite various suture fixation devices, nerve stimulation leads can be dislodged from the most efficacious location due to stresses placed on the lead by the ambulatory patient. A surgical intervention is then necessary to reposition the electrode and affix the lead. The implantable pulse generator ('IPG') is programmed to deliver stimulation pulse energy to the electrode providing the optimal nerve response. The efficacy of the selected electrode can fade over time due to dislodgement or other causes.

"Physicians spend a great deal of time with the patient under a general anesthetic placing the small size stimulation electrodes relative to the target nerves. The patient is thereby exposed to the additional dangers associated with extended periods of time under a general anesthetic. Movement of the lead, whether over time from suture release or during implantation during suture sleeve installation, is to be avoided. As can be appreciated, unintended movement of any object positioned proximate a nerve may cause unintended nerve damage. Moreover reliable stimulation of a nerve requires consistent nerve response to the electrical stimulation that, in turn, requires consistent presence of the stimulation electrode proximate the target nerve. On the other hand, if the target nerve is too close to the electrode, inflammation or injury to the nerve can result, diminishing efficacy and possibly causing patient discomfort.

"Cardiac pacing leads are commonly provided with passive fixation mechanisms that non-invasively engage heart tissue in a heart chamber or cardiac blood vessel or active fixation mechanisms that invasively extend into the myocardium from the endocardium or epicardium. Endocardial pacing leads having pliant tines that provide passive fixation within interstices of trabeculae in the right ventricle and atrial appendage are well known in the art as exemplified by U.S. Pat. Nos. 3,902,501, 3,939,843, 4,033,357, 4,236,529, 4,269,198, 4,301,815, 4,402,328, 4,409,994, and 4,883,070, for example. Such tined leads typically employ tines that extend outwardly and proximally from a band proximal to a distal tip pace/sense electrode and that
catch in natural trabecular interstices when the distal tip electrode is advanced into the atrial appendage or the ventricular apex.

"Certain spinal cord stimulation leads have been proposed employing tines and/or vanes as stand-offs to urge the stimulation electrode in the epidural space toward the spinal cord as disclosed in U.S. Pat. Nos. 4,590,949 and 4,658,535, for example, and to stabilize the stimulation electrode in the epidural space as disclosed in U.S. Pat. No. 4,414,986, for example.

"Stimulation leads for certain pelvic floor disorders have been proposed with a fixation mechanism that includes a plurality of tine elements arrayed in a tine element array along a segment of the lead proximal to the stimulation electrode array, such as for example in U.S. Pat. Nos. 6,999,819; 7,330,764; 7,912,555; 8,000,805; and 8,036,756. Each tine element includes a plurality of flexible, pliant, tines. The tines are configured to be folded inward against the lead body when fitted into and constrained by the lumen of an introducer.

"Peripheral nerve field stimulation ('PNFS') involves delivery of stimulation to a specific peripheral nerve via one or more electrodes implanted proximate to or in contact with a peripheral nerve, such as disclosed in U.S. Pat. Publication No. 2009/0281594. PNFS may be used to deliver stimulation to, for example, the vagal nerves, cranial nerves, trigeminal nerves, ulnar nerves, median nerves, radial nerves, tibial nerves, and the common peroneal nerves. When PNFS is delivered to treat pain, one or more electrodes are implanted proximate to or in contact with a specific peripheral nerve that is responsible for the pain sensation.

"Tined leads can create problems during removal or explant. In particular, the human body recognizes a lead as a foreign body and forms fibrous tissue around the lead. The fibrous tissue strengthens the engagement with the tines. If the anchoring of the tines is stronger than the lead itself, the lead may break during removal, leaving fragments behind. These fragments can migrate creating pain and increasing the risk of infection. Additional surgery is often required to remove the fragments."

Supplementing the background information on this patent, NewsRx reporters also obtained the inventors' summary information for this patent: "The present disclosure is directed to a therapy delivery element configured for at least partial insertion in a living body. The therapy delivery element includes a plurality of fibers braided to form an elongated braided structure with a lumen. At least one reinforcing structure is woven into the fibers of the braided structure. A portion of the reinforcing structure extends from the braided structure to form a fixation structure. A conductor assembly including a plurality of conductors is located in the lumen. An electrode assembly is located at a distal end of the conductor assembly. The electrode assembly includes a plurality of electrodes that are electrically coupled to the conductors. A connector assembly is located at a proximal end of the conductor assembly. The connector assembly includes a plurality of electrical contacts that are electrically coupled to the conductors. At least one of the braided structure or the reinforcing structure is attached to at least one of the electrode assembly or the connector assembly.

"The braided structure can be attached to both the electrode assembly and the connector assembly. The reinforcing structure is preferably attached to at least the connector assembly. At least one reinforcing structure preferably extends substantially the entire length of the braided structure.

"In one embodiment, a tubular structure surrounds the braided structure. The tubular structure is preferably bonded to the braided structure. In one embodiment, the tubular structure is a thermoplastic material melted into engagement with the braided structure. The at least one reinforcing structure is preferably bonded to the braided structure.

"The fixation structure is preferably a distal end of the at least one reinforcing
structure pulled from the braided structure. The fixation structures can be distal ends of a plurality of the reinforcing structures pulled from the braided structure to form a plurality of fixation structures. The braided structure preferably includes least one reinforcing structure that extends the entire length of the braided structure. The fixation structures preferably have a shape configured to fold against the lead body during removal of the therapy delivery element from the living body.

"In one embodiment, a plurality of fixation structures is radially spaced around the elongated braided structure. The fixation structures can be axially and/or radially offset along the elongated braided structure.

"The braided structure and the reinforcing structure increase the tensile strength of the therapy delivery element by about at least about 15%, and more preferably at least about 30%. The fixation structures preferably have a length of at least about 0.050 inches.

"The present disclosure is also directed to a neurostimulation system including an implantable pulse generator. A therapy delivery element as discussed herein is provided. The electrical contacts on the connector assembly are configured to electrically couple with the implantable pulse generator. At least one of the braided structure or the reinforcing structure is attached to at least one of the electrode assembly or the connector assembly.

"The present disclosure is also directed to a method of making a therapy delivery element configured for at least partial insertion in a living body. The method includes braiding a plurality of fibers to form an elongated braided structure with a lumen. At least one reinforcing structure is woven into the fibers of the braided structure. A portion of the reinforcing structure extends from the braided structure to form at least one fixation structure. A conductor assembly with a plurality of conductors is located in the lumen of the braided structure. Electrodes on an electrode assembly are electrically coupled to the conductors. The electrode assembly is attached to a distal end of the conductor assembly. Electrical contacts on a connector assembly are electrically coupled to the conductors. The connector assembly is attached to a proximal end of the conductor assembly. At least one of the braided structure or the reinforcing structure is attached to at least one of the electrode assembly and the connector assembly.

"The method optionally includes attaching both the electrode assembly and the connector assembly to the braided structure. The method also optionally includes attaching the reinforcing structure to at least the connector assembly. In one embodiment, the method includes locating a tubular structure around the braided structure and bonding the tubular structure to the braided structure.

"In one embodiment, a distal end of at least one reinforcing structure is removed from the braided structure to form the fixation structure. The fixation structure can be shaped to fold against the lead body during removal of the therapy delivery element from the living body."
New York University

Patent Issued for Methods and Agents for Preventing and Treating Plasma Cell Dyscrasias (USPTO 9526712)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- According to news reporting originating from Alexandria, Virginia, by NewsRx journalists, a patent by the inventors Orlov, Seth J. (New York, NY); Mazumder, Amitabha (East Setauket, NY); Doudican, Nicole (New York, NY), filed on February 25, 2014, was published online on December 27, 2016.

The assignee for this patent, patent number 9526712, is New York University (New York, NY).

Reporters obtained the following quote from the background information supplied by the inventors: "The citation of references herein shall not be construed as an admission that such is prior art to the present invention.

"Monoclonal gammopathy of undetermined significance (MGUS) and smoldering multiple myeloma (SMM) are asymptomatic myeloproliferative disorders characterized by monoclonal plasma cell proliferation. It is estimated that approximately 5% of the population above the age of 50 is affected by plasma cell dyscrasias [Kyle et al. N Engl J Med 354, 1362-1369, 2006]. Both conditions consistently precede multiple myeloma (MM), an incurable malignancy of terminally differentiated B cells, with recent studies demonstrating that these conditions represent one disease on a disease spectrum [Landgren. Hematology Am Soc Hematol Educ Program 2010, 295-302]. For patients with MGUS or SMM, the lifetime risk of progression to MM is estimated to be 15-59% [Perez-Persona et al. Blood 110, 2586-2592, 2007]. Consequently, MGUS and SMM patients require indefinite follow-up. Currently there is no accepted prevention or treatment strategy available for either condition--patients simply undergo continuous monitoring of plasma markers [Kumar. Cancer Treat Rev 36 Suppl 2, S3-11].

"Once MM develops, patients typically receive the proteasome inhibitor bortezomib (BTZ) as first line treatment. BTZ has demonstrated remarkable response rates in both relapsed and newly diagnosed MM. By virtue of inhibiting the proteasome, BTZ causes accumulation of misfolded proteins in the endoplasmic reticulum (ER) and activation of the unfolded protein response (UPR), which culminates in induction of caspase 12-mediated apoptosis [Chari et al. Biologics 4, 273-287, 2010]. An expansive, well developed rough ER highly specialized for the constant synthesis and secretion of large amounts of protein, namely immunoglobulin (Ig), is a defining characteristic of plasma cells. The innate biology of this class of cells is believed to account for the exquisite sensitivity of plasma cell disorders to agents like BTZ which target ER stress related signaling pathways to induce apoptosis.

"Given the clinically validated importance of targeting ER stress pathways in the treatment of MM and the biological similarities that exist between SMM and MM [Shah et al. Leukemia 23, 1964-1979, 2009], BTZ is also predicted to be effective in the management of MGUS and/or SMM. However, BTZ carries the potential for serious side effects; for example, more than 30% of the patients receiving BTZ treatment develop painful peripheral neuropathy [Cavaletti. Lancet Oncol 12, 120-121]. In fact, Takeda Pharmaceuticals recently received FDA approval for administration of BTZ by subcutaneous injection in an effort to reduce the number of patients experiencing severe nerve damage. It is expected that this will become the preferred route of administration. This route of administration, however, along with the potential for harmful side effects, precludes BTZ from being used in the treatment of MGUS/SMM."
In addition to obtaining background information on this patent, NewsRx editors also obtained the inventors' summary information for this patent: "In a first aspect, a method for treating and/or preventing a myeloproliferative disorder characterized by monoclonal plasma cell proliferation in a subject is presented, the method comprising administering a therapeutically effective amount of S-allylcysteine (SAC), a compound comprising SAC, or a composition thereof to a patient afflicted with such a disorder so as to target cells involved in these disorders for cell killing via ER stress mediated pathways. In so doing, the method effectively reduces the number of proliferating monoclonal plasma cells in the subject, thereby treating the subject.

"In a second aspect, a method for treating and/or preventing a myeloproliferative disorder characterized by monoclonal plasma cell proliferation in a subject is presented, wherein the myeloproliferative disorder is an asymptomatic myeloproliferative disorder or a symptomatic myeloproliferative disorder, the method comprising administering a therapeutically effective amount of S-allylcysteine (SAC), a compound comprising SAC, or a composition thereof to a patient afflicted with such a disorder so as to target cells involved in these disorders for cell killing via ER stress mediated pathways. In a particular aspect, the asymptomatic myeloproliferative disorder is monoclonal gammopathy of undetermined significance (MGUS) or smoldering multiple myeloma (SMM). In another particular aspect, the symptomatic myeloproliferative disorder is multiple myeloma (MM). In a particular embodiment thereof, the subject has treatment resistant or refractive MM. Such embodiments may further comprise a chemotherapeutic agent, such as, for example, bortezomib (BTZ). BTZ may be administered before, concomitantly, or after SAC or a compound or composition thereof at the discretion of a skilled practitioner. In yet another embodiment, the subject is in remission following successful treatment for MM and methods described herein are implemented to slow or prevent relapse in the patient. Under such circumstances, the methods are implemented for preventive or prophylactic purposes.

"In a particular embodiment, the compound or composition consists essentially of SAC or consists of SAC.

"In another particular embodiment, the subject is a mammal. In a more particular embodiment, the subject is a human.

"In another aspect, a method for treating and/or preventing a myeloproliferative disorder characterized by monoclonal plasma cell proliferation in a patient or patient population is presented, the method comprising providing a patient afflicted with an asymptomatic myeloproliferative disorder or providing a patient population comprising patients afflicted with an asymptomatic myeloproliferative disorder and administering a therapeutically effective amount of S-allylcysteine (SAC), a compound comprising SAC, or a composition thereof to the patient or each one of the patients afflicted with the asymptomatic myeloproliferative disorder so as to target cells involved in this disorder for cell killing via ER stress mediated pathways. In a particular embodiment thereof, the patient or patient population has either MGUS or SMM. In a further embodiment thereof, the patient is a mammal (e.g., a human) or the patient population comprises mammals (e.g., humans). In a particular embodiment, the compound or composition consists essentially of SAC or consists of SAC.

"In another aspect, a method for treating and/or preventing a myeloproliferative disorder characterized by monoclonal plasma cell proliferation in a patient or patient population is presented, the method comprising selecting the patient afflicted with a symptomatic myeloproliferative disorder or patient population comprising patients afflicted with a symptomatic myeloproliferative disorder and administering a therapeutically effective amount of S-allylcysteine (SAC), a compound comprising SAC, or a composition thereof to the patient or each one of the patients afflicted with the symptomatic myeloproliferative disorder so as to
target cells involved in this disorder for cell killing via ER stress mediated pathways. In a particular embodiment thereof, the patient population has MM. In a particular embodiment thereof, the subject has treatment resistant or refractive MM. Such embodiments may further comprise a chemotherapeutic agent, such as, for example, bortezomib (BTZ). BTZ may be administered before, concomitantly, or after SAC or a compound or composition thereof at the discretion of a skilled practitioner. In yet another embodiment, the subject is in remission following successful treatment for MM and methods described herein are implemented to slow or prevent relapse in the patient. Under such circumstances, the methods are implemented for preventive or prophylactic purposes. In a further embodiment thereof, the patient population comprises mammals (e.g., humans). In a particular embodiment, the compound or composition consists essentially of SAC or consists of SAC.

"As described herein, the therapeutically effective amount of S-allylcysteine (SAC), a compound comprising SAC, or a composition thereof may be administered via a nutraceutical, a dietary supplement, or a drug. In a particular embodiment, the therapeutically effective amount of S-allylcysteine (SAC) is administered orally. In a more particular embodiment, the therapeutically effective amount of S-allylcysteine (SAC) is administered via AGE tablets. A suitable therapeutic regimen of AGE tablets comprises about 500-2,500 mg of AGE administered per day. In a particular embodiment thereof, three 500 mg AGE tablets are administered per day.

"Efficacy of the preventative and/or therapeutic methods described herein can be assessed by assaying a number of parameters, including: measuring the free light-chain ratio (rFLC) and the difference between clonal and nonclonal light-chain (dFLC) and involved free light-chain (iFLC), wherein a reduction in any of these parameters is a positive indicator of efficacy. A decrease in urinary deoxypyridinoline (uDPYD), a marker of bone resorption is also an indicator of efficacy, as is a decrease in serum creatinine levels.

"In another aspect, S-allylcysteine (SAC) or a compound or composition thereof is presented for use in the treatment of a myeloproliferative disorder in a subject, wherein the SAC or the compound or composition thereof is administered in a therapeutically effective amount to the subject. The myeloproliferative disorder may be an asymptomatic myeloproliferative disorder or a symptomatic myeloproliferative disorder. In a particular embodiment, the asymptomatic myeloproliferative disorder is MGUS or SMM. In another embodiment, the symptomatic myeloproliferative disorder is MM. In a more particular embodiment, the symptomatic myeloproliferative disorder is treatment resistant MM. Under such circumstances, the aforementioned use may be supplemented with use of chemotherapeutic agent, such as, for example, bortezomib (BTZ). Use of BTZ may entail administering before, concomitantly, or after SAC or a compound or composition thereof at the discretion of a skilled practitioner. In another embodiment, the aforementioned use is envisioned for treating a subject in remission following successful treatment of MM, in which case, the use of SAC or a compound or composition thereof is directed to preventive or prophylactic treatment of such patients so as to delay or prevent relapse to MM. As described herein, subjects and patients may be mammals, and more particularly, may be humans. In a more particular embodiment, the SAC or compound or composition thereof used consists essentially of SAC or consists of SAC.

"The therapeutically effective amount of S-allylcysteine (SAC) or the compound or composition thereof is administrable via a nutraceutical, a dietary supplement, or a drug. It may, moreover, be used in an oral formulation. AGE tablets are set forth as exemplary tablets for oral administration. An exemplary dosing regimen calls for use of about 500-2,500 mg of AGE per day. In a particular embodiment thereof, a dosing regimen comprises use of a total of three 500 mg AGE tablets per day. As described herein, efficacy may be determined by measuring clinical indicators of disease comprising free light-chain ratio (rFLC), a differential between clonal and
nonclonal light-chain (dFLC), involved free light-chain (iFLC), urinary deoxypyridinoline (uDPYD), and/or serum creatinine levels. In a particular embodiment, a decrease in any one of these clinical indicators of disease is a positive indicator of efficacy.

"In another aspect, use of S-allylcysteine (SAC) or a compound or composition thereof for the manufacture of a medicament for treating a myeloproliferative disorder in a subject is envisioned, wherein the medicament is prepared to be administered in a dosage regime whereby SAC or the compound or composition thereof is delivered in a therapeutically effective amount to the subject. The myeloproliferative disorder may be an asymptomatic myeloproliferative disorder (e.g., MGUS or SMM) or a symptomatic myeloproliferative disorder (e.g., MM). In a particular embodiment thereof, the medicament is prepared to be administered to a subject with treatment resistant MM. This embodiment may further comprise a medicament comprising a chemotherapeutic agent, such as, for example, bortezomib (BTZ), which may be administered in conjunction with a medicament comprising SAC or a compound or composition thereof. The medicament comprising BTZ may be administered before, concomitantly, or after a medicament comprising SAC or a compound or composition thereof at the discretion of a skilled practitioner. In another embodiment, the medicament is prepared to be administered to a subject in remission following successful treatment for MM. In accordance with such an implementation, the medicament is administered for preventive or prophylactic purposes so as to delay or prevent relapse to MM. In a particular embodiment, the subject is a mammal. In a more particular embodiment, the mammal is a human. In an even more particular embodiment, the medicament consists essentially of SAC or consists of SAC.

"The medicament may be prepared to be administered in the form of a nutraceutical, a dietary supplement, or a drug. In a particular embodiment thereof, the medicament is prepared to be administered orally. In a more particular embodiment, the medicament comprises AGE tablets, which are administrable in a dosing regimen of about 500-2,500 mg of AGE administered per day. In a still more particular embodiment, a total of three 500 mg AGE tablets are administered per day. Efficacy of the medicament may be determined by measuring clinical indicators of disease comprising free light-chain ratio (rFLC), a differential between clonal and nonclonal light-chain (dFLC), involved free light-chain (iFLC), urinary deoxypyridinoline (uDPYD), and/or serum creatinine levels, wherein a decrease in any one of the clinical indicators of disease is a positive indicator of efficacy.

"Other objects and advantages will become apparent to those skilled in the art from a review of the ensuing detailed description, which proceeds with reference to the following illustrative drawings, and the attendant claims."

ABBOTT LABORATORIES

Patent Issued for Methods and Reagents for Diagnosing Rheumatoid Arthritis (USPTO 9528998)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- According to news reporting originating from Alexandria, Virginia, by NewsRx journalists, a patent by the inventors Yoshimura, Toru (Matsudo, JP); Chiba, Ryotaro (Matsudo, JP), filed on April 14, 2011, was published online on December 27, 2016.

The assignee for this patent, patent number 9528998, is ABBOTT LABORATORIES (Abbott Park, IL).

Reporters obtained the following quote from the background information supplied by the inventors: "Rheumatoid arthritis (RA) is a serious, chronic autoimmune disease that afflicts about 1% of the world's population. Women are affected three times more often than men. RA primarily attacks the joints, where an inflammatory synovitis frequently destroys articular cartilage and causes ankylosis. RA may involve other tissues in diffuse inflammation including lungs, pericardium, pleura, and sclera. RA is both crippling and painful, and frequently leads to substantial loss of mobility and overall function.

"Diagnosis of RA is typically based initially on clinical signs and symptoms, but because the clinical indicators of RA are shared with a number of other common diseases and conditions, the clinical evaluation is usually supplemented by X-rays, and by blood tests for known markers, such as rheumatoid factor (RF). Thus, when RA is suspected from observation of clinical signs and symptoms, blood tests such as those testing for the presence of RF are typically used to help confirm a diagnosis. Known markers however do not necessarily detect RA with a very high level of sensitivity to RA and specificity for RA. For example, particularly during the earliest stages of RA in the first year, about 15-20% of patients do not seroconvert to RF and therefore an RF test on such a patient during this time will produce a false negative result. Moreover, RF is not 100% specific to RA, being present in about 10% of the healthy population and also in individuals with other inflammatory diseases or conditions, especially Sjogren's syndrome but also chronic hepatitis, any chronic viral infection, leukemia, dermatomyositis, infectious mononucleosis, systemic sclerosis and systemic lupus erythematosus. RF tests on such individuals will produce a significant number of false positive results. Serological markers of RA also include anti-citrullinated protein antibodies (ACPAs), as tested in the anti-CCP (cyclic citrullinated peptide) test and the anti-MCV (antibodies against mutated citrullinated Vimentin) assay, which also produce significant numbers of false positive and/or false positive results with respect to RA. Markers of RA with improved sensitivity and specificity for RA are needed so that positive diagnoses of RA can be confirmed as early as possible in the course of the disease."

In addition to obtaining background information on this patent, NewsRx editors also obtained the inventors' summary information for this patent: "The present disclosure shows that the level of CCL-8 (Chemokine c-c motif Ligand 8) protein in a blood sample from a subject is a positive indicator of the presence of rheumatoid arthritis in the subject, with a high level of sensitivity and specificity. Moreover, levels of CCL8 in the blood are positively correlated with the severity of the disease in the subject, such that, for example, an elevated level of CCL8 in the blood indicates a severe case of rheumatoid arthritis.

"Accordingly, in one aspect, the present disclosure provides a method for diagnosing rheumatoid arthritis in a subject comprising measuring the level of CCL8 protein in a test sample obtained from the subject wherein the level of CCL8 protein in the test sample indicates
presence or absence of rheumatoid arthritis in the subject. The presence or absence of rheumatoid arthritis can be determined before clinical indicators of rheumatoid arthritis are present in the subject. The level of CCL8 protein in the test sample can be measured for example using an anti-CCL8 antibody. The test sample can be a blood sample including a plasma or a serum sample. The method may further comprise measuring the level of one or more additional markers of rheumatoid arthritis in the sample, wherein the level of each additional marker in the test sample further indicates presence or absence of rheumatoid arthritis in the subject. Such markers include for example CRP, a-CCP, CARF IgG, MMP-3 and Rheumatoid factor.

"In another aspect the present disclosure provides a method for determining the severity of rheumatoid arthritis in a subject comprising determining the presence or absence of an elevated level of CCL8 protein in a test sample obtained from the subject wherein the presence of an elevated level of CCL8 protein indicates that the rheumatoid arthritis in the subject is severe. The method may further comprise measuring the level of one or more markers of rheumatoid arthritis in the sample wherein the markers are selected from the group consisting of: CRP, a-CCP, CARF IgG, MMP-3 and Rheumatoid factor, wherein the level of the one or more markers in the test sample further indicates presence or absence of rheumatoid arthritis in the subject.

"In another aspect the present disclosure provides a diagnostic reagent for rheumatoid arthritis comprising an anti-CCL8 antibody or fragment thereof, and an antibody against at least one marker of rheumatoid arthritis selected from the group consisting of: CRP, a-CCP, CARF IgG, MMP-3 and Rheumatoid factor. The diagnostic reagent may be included in a diagnostic kit.

"In another aspect the present disclosure provides a method for identifying a candidate substance as a therapeutic agent for treating rheumatoid arthritis, comprising: a) administering a test substance to an animal subject having an animal model of rheumatoid arthritis; b) measuring the level of CCL8 protein in a test sample obtained from the animal subject; and c) selecting the test substance as a candidate substance as a therapeutic agent for treating rheumatoid arthritis substance if the level of CCL8 protein in the test sample is lower than the level of CCL8 protein in a test sample from a comparable animal subject not administered the test substance.

"In another aspect the present disclosure encompasses use of an anti-CCL8 antibody or fragment thereof as a diagnostic reagent for the diagnosis of rheumatoid arthritis in a subject.

"In another aspect the present disclosure encompasses use of an anti-CCL8 antibody or fragment thereof as an active ingredient in a pharmaceutical composition for the treatment of rheumatoid arthritis in a subject.

"In another aspect the present disclosure encompasses use of an anti-CCL8 antibody or fragment thereof in the manufacture of a reagent for the diagnosis of rheumatoid arthritis in a subject.

"In another aspect the present disclosure encompasses use of an anti-CCL8 antibody or fragment thereof in the manufacture of a pharmaceutical composition for the treatment of rheumatoid arthritis in a subject.

"In another aspect the present disclosure provides a method for monitoring the effect of a treatment of rheumatoid arthritis in a subject comprising: a) measuring a first level of CCL8 protein in a first test sample obtained from the subject before the treatment; b) measuring a second level of CCL8 protein in a second test sample obtained from the subject after the treatment begins; and c) comparing the first level of CCL8 protein and the second level of CCL8 protein, wherein a second level of CCL8 protein level that is lower than the first level of CCL8
protein is indicative of a therapeutic effect of the treatment in the subject.

"In any of the above methods, the level of CCL8 protein in the test sample can be measured for example using an anti-CCL8 antibody. In any of the above methods, the test sample(s) can be blood samples including plasma or serum samples. In any of the above methods, the level of CCL8 protein can be measured using a method selected from the group consisting of: mass spectrometry, high performance liquid chromatography, and two-dimensional electrophoresis."

Quest Diagnostics Investments Incoporated

**Patent Issued for Methods for Detecting Lacosamide by Mass Spectrometry (USPTO 9530635)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- According to news reporting originating from Alexandria, Virginia, by NewsRx journalists, a patent by the inventors Boyadzhyan, Beatrisinga (San Juan Capistrano, CA); Thomassian, Karin (San Juan Capistrano, CA); Dermartirosian, Anita (San Juan Capistrano, CA); Jambor, Lou (San Juan Capistrano, CA), filed on June 30, 2014, was published online on December 27, 2016.

The assignee for this patent, patent number 9530635, is Quest Diagnostics Investments Incorporated (Wilmington, DE).

Reporters obtained the following quote from the background information supplied by the inventors: "The following description of the background of the invention is provided simply as an aid in understanding the invention and is not admitted to describe or constitute prior art to the invention.

"Lacosamide (also known as Vimpat.TM., erlosamide, and harkoseride) is a functionalized amino acid that is used as an adjunctive therapy the treatment of partial-onset seizures (Halasz et al., Epilepsia, 50(3):443-453, 2009). Lacosamide is also being investigated as a treatment for diabetic neuropathic pain (Ziegler et al. Diabetes Care. 2010 April; 33 (4):839-41). Lacosamide has dual mechanisms of action. In one mechanism, lacosamide selectively enhances slow inactivation of voltage-gated sodium channels, which in turn stabilizes hyperexcitable neuronal membranes and inhibits neuronal firing (Sheets et al., J Pharmacol Exp Ther. 2008 July; 326(1):89-99; Errington et al., Mol Pharmacol. 2008 January; 73(1):157-69). In another mechanism of action, lacosamide modulates collapsin response mediator protein-2 (CRMP-2), a protein that has altered expression in epilepsy and other
neurodegenerative diseases (Cada et al., Hospital Pharmacy 2009 June; 44(6), 497-508).

"Assays for lacosamide blood levels have been developed and are used by patients and physicians to optimize therapeutic dosages."

In addition to obtaining background information on this patent, NewsRx editors also obtained the inventors' summary information for this patent: "The present invention provides methods for detecting the amount of lacosamide in a sample by mass spectrometry, including tandem mass spectrometry.

"In one aspect, methods are provided for determining the amount of lacosamide in a sample. Methods of this aspect include: (a) ionizing lacosamide from the sample to produce one or more lacosamide ions detectable by mass spectrometry, wherein the ions comprise one or more ions selected from the group consisting of ions with a mass/charge ratio of 251.0.+-0.5, 91.0.+-0.5, and 108.0.+-0.5; (b) determining the amount of one or more lacosamide ions by mass spectrometry; and © using the amount of the lacosamide ion(s) to determine the amount of lacosamide in the sample. In some embodiments, the mass spectrometry is tandem mass spectrometry. In some embodiments, the methods further include purifying lacosamide in the sample prior to mass spectrometry. In some embodiments, purifying includes purifying with liquid chromatography. In related embodiments, the liquid chromatography comprises high performance liquid chromatography (HPLC). In some embodiments, purifying includes one or more purification steps followed by liquid chromatography. In related embodiments, the one or more purification steps prior to liquid chromatography include protein precipitation. In some embodiments, the sample is generated by subjecting a body fluid to one or more processing steps. In some embodiments, the sample is generated by subjecting plasma or serum to one or more processing steps. In some embodiments, ionizing includes generating a lacosamide precursor ion with a mass/charge ratio of 251.0.+-0.5, and generating one or more lacosamide fragment ions selected from the group consisting of ions with a mass/charge ratio of 91.0.+-0.5 and 108.0.+-0.5. In some embodiments, ionizing is conducted in positive ion mode. In some embodiments, the method has a lower limit of quantitation within the range of 20 .mu.g/ml and 0.5 .mu.g/ml, inclusive.

"In a second aspect, methods are provided for determining the amount of lacosamide in a body fluid sample by tandem mass spectrometry. Methods of this aspect include: (a) ionizing lacosamide, purified from the body fluid sample by liquid chromatography, to generate a lacosamide precursor ion having a mass/charge ratio of 251.0.+-0.5; (b) producing one or more lacosamide fragment ions of the lacosamide precursor ion, wherein at least one of the one or more lacosamide fragment ions comprise an ion selected from the group of ions having a mass/charge ratio of 91.0.+-0.5 and 108.0.+-0.5; and © determining the amount of one or more of the ions generated in step (b) or © or both and relating the determined ions to the amount of lacosamide in the body fluid sample. In some embodiments, the methods have a lower limit of quantitation within the range of 20 .mu.g/ml and 0.5 .mu.g/ml, inclusive. In some embodiments, the liquid chromatography includes high performance liquid chromatography (HPLC). In some embodiments, the lacosamide purified from a body fluid sample is purified by one or more purification steps followed by liquid chromatography. In related embodiments, the one or more purification steps prior to liquid chromatography include protein precipitation. In some embodiments, the body fluid sample includes plasma or serum. In some embodiments, ionization is conducted in positive ion mode.

"As used herein, unless otherwise stated, the singular forms 'a,' 'an,' and 'the' include plural reference. Thus, for example, a reference to 'a protein' includes a plurality of protein molecules.

"As used herein, the term 'processing step' refers to any sample handling step without
limitation, including, for example: heating, cooling, centrifugation, or purification by any method known in the art. In particular, purification steps may include one or more of filtration, protein precipitation, liquid-liquid extraction, solid-phase extraction, liquid chromatography (including high performance liquid chromatography), and the like.

"As used herein, the term 'purification' or 'purifying' does not refer to removing all materials from the sample other than the analyte(s) of interest. Instead, purification refers to a procedure that enriches the amount of one or more analytes of interest relative to other components in the sample that may interfere with detection of the analyte of interest. Purification of the sample by various means may allow relative reduction of one or more interfering substances, e.g., one or more substances that may or may not interfere with the detection of selected lacosamide parent or daughter ions by mass spectrometry. Relative reduction as this term is used does not require that any substance, present with the analyte of interest in the material to be purified, is entirely removed by purification.

"As used herein, the term 'sample' refers to any sample that may contain lacosamide. As used herein, the term 'body fluid' means any fluid that can be isolated from the body of an individual. For example, 'body fluid' may include blood, plasma, serum, bile, saliva, urine, tears, perspiration, and the like.

"As used herein, the term 'chromatography' refers to a process in which a chemical mixture carried by a liquid or gas is separated into components as a result of differential distribution of the chemical entities as they flow around or over a stationary liquid or solid phase.

"As used herein, the term 'liquid chromatography' or 'LC' means a process of selective retardation of one or more components of a fluid solution as the fluid uniformly percolates through a column of a finely divided substance, or through capillary passageways. The retardation results from the distribution of the components of the mixture between one or more stationary phases and the bulk fluid, (i.e., mobile phase), as this fluid moves relative to the stationary phase(s). Examples of 'liquid chromatography' include reverse phase liquid chromatography (RPLC), high performance liquid chromatography (HPLC), and high turbulence liquid chromatography (HTLC).

"As used herein, the term 'high performance liquid chromatography' or 'HPLC' refers to liquid chromatography in which the degree of separation is increased by forcing the mobile phase under pressure through a stationary phase on a support matrix, typically a densely packed column.

"As used herein, the term 'high turbulence liquid chromatography' or 'HTLC' refers to a form of chromatography that utilizes turbulent flow of the material being assayed through the column packing as the basis for performing the separation. HTLC has been applied in the preparation of samples containing two unnamed drugs prior to analysis by mass spectrometry. See, e.g., Zimmer et al., J. Chromatogr. A 854: 23-35 (1999); see also, U.S. Pat. Nos. 5,968,367, 5,919,368, 5,795,469, and 5,772,874, which further explain HTLC. Persons of ordinary skill in the art understand 'turbulent flow'. When fluid flows slowly and smoothly, the flow is called 'laminar flow'. For example, fluid moving through an HPLC column at low flow rates is laminar. In laminar flow the motion of the particles of fluid is orderly with particles moving generally in straight lines. At faster velocities, the inertia of the water overcomes fluid frictional forces and turbulent flow results. Fluid not in contact with the irregular boundary 'outruns' that which is slowed by friction or deflected by an uneven surface. When a fluid is flowing turbulently, it flows in eddies and whirls (or vortices), with more 'drag' than when the flow is laminar. Many references are available for assisting in determining when fluid flow is laminar or turbulent (e.g., Turbulent Flow Analysis: Measurement and Prediction, P. S. Bernard
"As used herein, the term 'gas chromatography' or 'GC' refers to chromatography in which the sample mixture is vaporized and injected into a stream of carrier gas (as nitrogen or helium) moving through a column containing a stationary phase composed of a liquid or a particulate solid and is separated into its component compounds according to the affinity of the compounds for the stationary phase.

"As used herein, the term 'large particle column' or 'extraction column' refers to a chromatography column containing an average particle diameter greater than about 35 \( \mu \text{m} \), such as greater than about 50 \( \mu \text{m} \).

"As used herein, the term 'analytical column' refers to a chromatography column having sufficient chromatographic plates to effect a separation of materials in a sample that elute from the column sufficient to allow a determination of the presence or amount of an analyte. Such columns are often distinguished from 'extraction columns', which have the general purpose of separating or extracting retained material from non-retained materials in order to obtain a purified sample for further analysis. As used in this context, the term 'about' means\( \pm \)10%. In a preferred embodiment the analytical column contains particles of about 5 \( \mu \text{m} \) in diameter.

"As used herein, the term 'on-line' or 'inline', for example as used in 'on-line automated fashion' or 'on-line extraction' refers to a procedure performed without the need for operator intervention. In contrast, the term 'off-line' as used herein refers to a procedure requiring manual intervention of an operator. Thus, if samples are subjected to precipitation, and the supernatants are then manually loaded into an autosampler, the precipitation and loading steps are off-line from the subsequent steps. In various embodiments of the methods, one or more steps may be performed in an on-line automated fashion.

"As used herein, the term 'mass spectrometry' or 'MS' refers to an analytical technique to identify compounds by their mass. MS refers to methods of filtering, detecting, and measuring ions based on their mass-to-charge ratio, or 'm/z'. MS technology generally includes (1) ionizing the compounds to form charged compounds; and (2) detecting the molecular weight of the charged compounds and calculating a mass-to-charge ratio. The compounds may be ionized and detected by any suitable means. A 'mass spectrometer' generally includes an ionizer and an ion detector. In general, one or more molecules of interest are ionized, and the ions are subsequently introduced into a mass spectrographic instrument where, due to a combination of magnetic and electric fields, the ions follow a path in space that is dependent upon mass ('m') and charge ('z'). See, e.g., U.S. Pat. No. 6,204,500, entitled 'Mass Spectrometry From Surfaces;' U.S. Pat. No. 6,107,623, entitled 'Methods and Apparatus for Tandem Mass Spectrometry;' U.S. Pat. No. 6,268,144, entitled 'DNA Diagnostics Based On Mass Spectrometry;' U.S. Pat. No. 6,124,137, entitled 'Surface-Enhanced Photolabile Attachment And Release For Desorption And Detection Of Analytes;' Wright et al., Prostate Cancer and Prostatic Diseases 2:264-76 (1999); and Merchant and Weinberger, Electrophoresis 21:1164-67 (2000).

"As used herein, the term 'operating in negative ion mode' refers to those mass spectrometry methods where negative ions are generated and detected. The term 'operating in positive ion mode' as used herein, refers to those mass spectrometry methods where positive ions are generated and detected.

"As used herein, the term 'ionization' or 'ionizing' refers to the process of generating an analyte ion having a net electrical charge equal to one or more electron units. Negative ions are those having a net negative charge of one or more electron units, while positive ions are those having a net positive charge of one or more electron units.
"As used herein, the term 'electron ionization' or 'EI' refers to methods in which an analyte of interest in a gaseous or vapor phase interacts with a flow of electrons. Impact of the electrons with the analyte produces analyte ions, which may then be subjected to a mass spectrometry technique.

"As used herein, the term 'chemical ionization' or 'CI' refers to methods in which a reagent gas (e.g. ammonia) is subjected to electron impact, and analyte ions are formed by the interaction of reagent gas ions and analyte molecules.

"As used herein, the term 'fast atom bombardment' or 'FAB' refers to methods in which a beam of high energy atoms (often Xe or Ar) impacts a non-volatile sample, desorbing and ionizing molecules contained in the sample. Test samples are dissolved in a viscous liquid matrix such as glycerol, thioglycerol, m-nitrobenzyl alcohol, 18-crown-6 crown ether, 2-nitrophenyloctyl ether, sulfolane, diethanolamine, and triethanolamine. The choice of an appropriate matrix for a compound or sample is an empirical process.

"As used herein, the term 'matrix-assisted laser desorption ionization' or 'MALDI' refers to methods in which a non-volatile sample is exposed to laser irradiation, which desorbs and ionizes analytes in the sample by various ionization pathways, including photo-ionization, protonation, deprotonation, and cluster decay. For MALDI, the sample is mixed with an energy-absorbing matrix, which facilitates desorption of analyte molecules.

"As used herein, the term 'surface enhanced laser desorption ionization' or 'SELDI' refers to another method in which a non-volatile sample is exposed to laser irradiation, which desorbs and ionizes analytes in the sample by various ionization pathways, including photo-ionization, protonation, deprotonation, and cluster decay. For SELDI, the sample is typically bound to a surface that preferentially retains one or more analytes of interest. As in MALDI, this process may also employ an energy-absorbing material to facilitate ionization.

"As used herein, the term 'electrospray ionization' or 'ESI,' refers to methods in which a solution is passed along a short length of capillary tube, to the end of which is applied a high positive or negative electric potential. Solution reaching the end of the tube is vaporized (nebulized) into a jet or spray of very small droplets of solution in solvent vapor. This mist of droplets flows through an evaporation chamber. As the droplets get smaller the electrical surface charge density increases until such time that the natural repulsion between like charges causes ions as well as neutral molecules to be released.

"As used herein, the term 'atmospheric pressure chemical ionization' or 'APCI,' refers to mass spectrometry methods that are similar to ESI; however, APCI produces ions by ion-molecule reactions that occur within a plasma at atmospheric pressure. The plasma is maintained by an electric discharge between the spray capillary and a counter electrode. Then ions are typically extracted into the mass analyzer by use of a set of differentially pumped skimmer stages. A counterflow of dry and preheated N.sub.2 gas may be used to improve removal of solvent. The gas-phase ionization in APCI can be more effective than ESI for analyzing less-polar species.

"The term 'atmospheric pressure photoionization' or 'APPI' as used herein refers to the form of mass spectrometry where the mechanism for the photoionization of molecule M is photon absorption and electron ejection to form the molecular ion M+. Because the photon energy typically is just above the ionization potential, the molecular ion is less susceptible to dissociation. In many cases it may be possible to analyze samples without the need for chromatography, thus saving significant time and expense. In the presence of water vapor or protic solvents, the molecular ion can extract H to form MH+. This tends to occur if M has a high proton affinity. This does not affect quantitation accuracy because the sum of M+ and MH+ is constant. Drug compounds in protic solvents are usually observed as MH+, whereas

"As used herein, the term 'inductively coupled plasma' or 'ICP' refers to methods in which a sample interacts with a partially ionized gas at a sufficiently high temperature such that most elements are atomized and ionized.

"As used herein, the term 'field desorption' refers to methods in which a non-volatile test sample is placed on an ionization surface, and an intense electric field is used to generate analyte ions.

"As used herein, the term 'desorption' refers to the removal of an analyte from a surface and/or the entry of an analyte into a gaseous phase.

"As used herein, the term 'selective ion monitoring' is a detection mode for a mass spectrometric instrument in which only ions within a relatively narrow mass range, typically about one mass unit, are detected.

"As used herein, 'multiple reaction mode,' sometimes known as 'selected reaction monitoring,' is a detection mode for a mass spectrometric instrument in which a precursor ion and one or more fragment ions are selectively detected.

"As used herein, the term 'lower limit of quantification', 'limit of quantitation' or 'LOQ' refers to the point where measurements become quantitatively meaningful. The analyte response at this LOQ is identifiable, discrete and reproducible and is calculated as the mean plus 10 standard deviations (SD).

"As used herein, the term 'limit of detection' or 'LOD' is the point at which the measured value is larger than the uncertainty associated with it. The LOD is the point at which a value is beyond the uncertainty associated with its measurement and is defined as four standard deviations from the zero concentration.

"As used herein, an 'amount' of lacosamide in a body fluid sample refers generally to an absolute value reflecting the mass of lacosamide detectable in volume of body fluid. However, an amount also contemplates a relative amount in comparison to another lacosamide amount. For example, an amount of lacosamide in a body fluid can be an amount which is greater than a control or normal level of lacosamide normally present.

"The term 'about' as used herein in reference to quantitative measurements not including the measurement of the mass of an ion, refers to the indicated value plus or minus 10%. Mass spectrometry instruments can vary slightly in determining the mass of a given analyte. The term 'about' in the context of the mass of an ion or the mass/charge ratio of an ion refers to +/-0.50 atomic mass unit.

"The summary of the invention described above is non-limiting and other features and advantages of the invention will be apparent from the following detailed description of the invention, and from the claims."

**Quest Diagnostics Investments Incorporated**

**Patent Issued for Methods for Detecting Vitamin D Metabolites by Mass Spectrometry (USPTO 9529004)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Quest Diagnostics Investments Incorporated (Wilmington, DE) has been issued patent number 9529004, according to news reporting originating out of Alexandria, Virginia, by NewsRx editors.

The patent's inventors are Clarke, Nigel J. (Oceanside, CA); Holmquist, Brett (Thousand Oaks, CA); Lee, Gloria Kwang-Ja (Irvine, CA); Reitz, Richard E. (San Clemente, CA).

This patent was filed on January 25, 2016 and was published online on December 27, 2016.

From the background information supplied by the inventors, news correspondents obtained the following quote: "Vitamin D is an essential nutrient with important physiological roles in the positive regulation of calcium (Ca.sup.2+) homeostasis. Vitamin D can be made de novo in the skin by exposure to sunlight or it can be absorbed from the diet. There are two forms of vitamin D; vitamin D.sub.2 (ergocalciferol) and vitamin D.sub.3 (cholecalciferol). Vitamin D.sub.3 is the form synthesized de novo by animals. It is also a common supplement added to milk products and certain food products produced in the United States. Both dietary and intrinsically synthesized vitamin D.sub.3 must undergo metabolic activation to generate bioactive metabolites. In humans, the initial step of vitamin D.sub.3 activation occurs primarily in the liver and involves hydroxylation to form the intermediate metabolite 25-hydroxyvitamin D.sub.3 (25-hydroxycholecalciferol; calcifediol; 25OHD.sub.3). Calcifediol is the major form of vitamin D.sub.3 in the circulation. Circulating 25OHD.sub.3 is then converted by the kidney to 1,25-dihydroxyvitamin D.sub.3 (calcitriol; 1,25(OH).sub.2D.sub.3), which is generally believed to be the metabolite of vitamin D.sub.3 with the highest biological activity.

"Vitamin D.sub.2 is derived from fungal and plant sources. Many over-the-counter dietary supplements contain ergocalciferol (vitamin D.sub.2) rather than cholecalciferol (vitamin D.sub.3). Drisdol, the only high-potency prescription form of vitamin D available in the United States, is formulated with ergocalciferol. Vitamin D.sub.2 undergoes a similar pathway of metabolic activation in humans as vitamin D.sub.3, forming the metabolites 25-hydroxyvitamin D.sub.2 (25OHD.sub.2) and 1,25-dihydroxyvitamin D.sub.3 (1,25(OH).sub.2D.sub.3). Vitamin D.sub.2 and vitamin D.sub.3 have long been assumed to be biologically equivalent in humans, however recent reports suggest that there may be differences in the bioactivity and bioavailability of these two forms of vitamin D (Armas et. al., (2004) J. Clin. Endocrinol. Metab. 89:5387-5391).

"Measurement of vitamin D, the inactive vitamin D precursor, is rare in clinical settings and has little diagnostic value. Rather, serum levels of 25-hydroxyvitamin D.sub.3 and 25-hydroxyvitamin D.sub.2 (total 25-hydroxyvitamin D; '25OHD') are a useful index of vitamin D nutritional status and the efficacy of certain vitamin D analogs. Therefore, the measurement of 25OHD is commonly used in the diagnosis and management of disorders of calcium
metabolism. In this respect, low levels of 25OHD are indicative of vitamin D deficiency associated with diseases such as hypocalcemia, hypophosphatemia, secondary hyperparathyroidism, elevated alkaline phosphatase, osteomalacia in adults and rickets in children. In patients suspected of vitamin D intoxication, elevated levels of 25OHD distinguishes this disorder from other disorders that cause hypercalcemia.

"Measurement of 1,25(OH)₂D is also used in clinical settings, however, this metabolite has a more limited diagnostic usefulness than 25OHD. Factors that contribute to limitations of the diagnostic values of 1,25(OH)₂D as an index of vitamin D status include the precision of the endogenous regulation of renal production of the metabolite and its short half-life in circulation. However, certain disease states such as kidney failure can be diagnosed by reduced levels of circulating 1,25(OH)₂D and elevated levels of 1,25(OH)₂D may be indicative of excess parathyroid hormone or may be indicative of certain diseases such as sarcoidosis or certain types of lymphoma.

Supplementing the background information on this patent, NewsRx reporters also obtained the inventors' summary information for this patent: "The present invention provides methods for detecting the presence or amount of a vitamin D metabolite in a sample by mass spectrometry, including tandem mass spectrometry. Preferably, the methods of the invention do not include derivatizing the vitamin D metabolites prior to the mass spectrometry analysis.

"In one aspect, the invention provides a method for determining the presence or amount of a vitamin D metabolite in a sample. The method may include: (a) ionizing the vitamin D metabolite, if present in the sample; and (b) detecting the presence or amount of the ion by mass spectrometry and relating presence or amount of the detected ion to the presence or amount of the vitamin D metabolite in the sample. In some preferred embodiments, the ionization step (a) may include (i) ionizing the vitamin D metabolite, if present in the sample, to produce an ion of the vitamin D metabolite; (ii) isolating the ion of step (i) by mass spectrometry to provide a precursor ion; and (iii) effecting a collision between the precursor ion and an inert collision gas to produce at least one fragment ion detectable in a mass spectrometer. Preferably, at least one of the fragment ions is specific for the vitamin D metabolite of interest.

In certain embodiments of the invention, the fragment ions to be detected include at least one fragment ion other than that which results solely by a dehydration or deamination of the precursor ion. In some particularly preferred embodiments, the precursor ion is a protonated and dehydrated ion of the vitamin D metabolite. In certain embodiments the vitamin D metabolite is one or more vitamin D metabolites selected from the group consisting of 25-hydroxyvitamin D₃; 25-hydroxyvitamin D₂; 1,25-dihydroxyvitamin D₂; and 1,25-dihydroxyvitamin D₃.

"In a related aspect, the invention provides a method for determining the presence or
amount of a vitamin D metabolite in a sample by tandem mass spectrometry. The method may involve (a) generating a protonated and dehydrated precursor ion of the vitamin D metabolite if present in the sample; (b) generating one or more fragment ions of the precursor ion; and © detecting the presence or amount of one or more of the ions generated in step (a) or (b) or both and relating the detected ions to the presence or amount of the vitamin D metabolite in the sample. In certain embodiments, the method is used to detect the presence or amount of two or more vitamin D metabolites in a single assay. Preferably, the method does not involve derivatizing the samples or the vitamin D metabolites prior to analysis by mass spectrometry. In certain embodiments the vitamin D metabolite is one or more vitamin D metabolites selected from the group consisting of 25-hydroxyvitamin D₃; 25-hydroxyvitamin D₂; 1,25-dihydroxyvitamin D₂; and 1,25-dihydroxyvitamin D₃.

"In another aspect the invention provides a method for determining the presence or amount of two or more vitamin D metabolites in a sample in a single assay. The method includes ionizing the vitamin D metabolites, if present in the sample, to generate ions specific for each of the vitamin D metabolites of interest, detecting the presence or amount of the ions by mass spectrometry, and relating the presence or amount of the ions to the presence or amount of the vitamin D metabolites in the sample. In certain embodiments the mass spectrometry analysis of the method is tandem mass spectrometry.

"As used herein, the term 'vitamin D metabolite' refers to any chemical species that may be found in the circulation of an animal which is formed by a biosynthetic or metabolic pathway for vitamin D or a synthetic vitamin D analog. Vitamin D metabolites include forms of vitamin D that are generated by a biological organism, such as an animal, or that are generated by biotransformation of a naturally occurring form of vitamin D or a synthetic vitamin D analog. In certain preferred embodiments, a vitamin D metabolite is formed by the biotransformation of vitamin D₃ or vitamin D₂. In particularly preferred embodiments, the vitamin D metabolite is one or more compounds selected from the group consisting of 25-hydroxyvitamin D₃, 25-hydroxyvitamin D₂, 1,25-dihydroxyvitamin D₂ and 1,25-dihydroxyvitamin D₃.

"As used herein, the term 'purification' refers to a procedure that enriches the amount of one or more analytes of interest relative to one or more other components of the sample. Purification, as used herein does not require the isolation of an analyte from all others. In preferred embodiments, a purification step or procedure can be used to remove one or more interfering substances, e.g., one or more substances that would interfere with the operation of the instruments used in the methods or substances that may interfere with the detection of an analyte ion by mass spectrometry.

"As used herein, 'biological sample' refers to any sample from a biological source. As used herein, 'body fluid' means any fluid that can be isolated from the body of an individual. For example, 'body fluid' may include blood, plasma, serum, bile, saliva, urine, tears, perspiration, and the like.

"As used herein, 'derivatizing' means reacting two molecules to form a new molecule. Derivatizing agents may include isothiocyanate groups, dinitro-fluorophenyl groups, nitrophenoxycarbonyl groups, and/or phthalaldehyde groups.

"As used herein, 'chromatography' refers to a process in which a chemical mixture carried by a liquid or gas is separated into components as a result of differential distribution of the chemical entities as they flow around or over a stationary liquid or solid phase.

"As used herein, 'liquid chromatography' (LC) means a process of selective retardation of one or more components of a fluid solution as the fluid uniformly percolates through a column of a finely divided substance, or through capillary passageways. The
retardation results from the distribution of the components of the mixture between one or more stationary phases and the bulk fluid, (i.e., mobile phase), as this fluid moves relative to the stationary phase(s). 'Liquid chromatography' includes reverse phase liquid chromatography (RPLC), high performance liquid chromatography (HPLC) and high turbulence liquid chromatography (HTLC).

"As used herein, the term 'HPLC' or 'high performance liquid chromatography' refers to liquid chromatography in which the degree of separation is increased by forcing the mobile phase under pressure through a stationary phase, typically a densely packed column.

"As used herein, the term 'gas chromatography' refers to chromatography in which the sample mixture is vaporized and injected into a stream of carrier gas (as nitrogen or helium) moving through a column containing a stationary phase composed of a liquid or a particulate solid and is separated into its component compounds according to the affinity of the compounds for the stationary phase.

"As used herein, 'mass spectrometry' (MS) refers to an analytical technique to identify compounds by their mass. MS technology generally includes (1) ionizing the compounds to form charged compounds; and (2) detecting the molecular weight of the charged compound and calculating a mass-to-charge ratio (m/z). The compound may be ionized and detected by any suitable means. A 'mass spectrometer' generally includes an ionizer and an ion detector. See, e.g., U.S. Pat. No. 6,204,500, entitled 'Mass Spectrometry From Surfaces;' U.S. Pat. No. 6,107,623, entitled 'Methods and Apparatus for Tandem Mass Spectrometry;' U.S. Pat. No. 6,268,144, entitled 'DNA Diagnostics Based On Mass Spectrometry;' U.S. Pat. No. 6,124,137, entitled 'Surface-Enhanced Photolabile Attachment And Release For Desorption And Detection Of Analytes;' Wright et al., Prostate Cancer and Prostatic Diseases 2:264-76 (1999); and Merchant and Weinberger, Electrophoresis 21:1164-67 (2000).

"The term 'electron ionization' as used herein refers to methods in which an analyte of interest in a gaseous or vapor phase interacts with a flow of electrons. Impact of the electrons with the analyte produces analyte ions, which may then be subjected to a mass spectrometry technique.

"The term 'chemical ionization' as used herein refers to methods in which a reagent gas (e.g. ammonia) is subjected to electron impact, and analyte ions are formed by the interaction of reagent gas ions and analyte molecules.

"The term 'fast atom bombardment' as used herein refers to methods in which a beam of high energy atoms (often Xe or Ar) impacts a non-volatile sample, desorbing and ionizing molecules contained in the sample. Test samples are dissolved in a viscous liquid matrix such as glycerol, thioglycerol, m-nitrobenzyl alcohol, 18-crown-6 crown ether, 2-nitrophenyloctyl ether, sulfolane, diethanolamine, and triethanolamine.

"The term 'field desorption' as used herein refers to methods in which a non-volatile test sample is placed on an ionization surface, and an intense electric field is used to generate analyte ions.

"The term 'ionization' as used herein refers to the process of generating an analyte ion having a net electrical charge equal to one or more electron units. Negative ions are those having a net negative charge of one or more electron units, while positive ions are those having a net positive charge of one or more electron units.

"The term 'operating in negative ion mode' refers to those mass spectrometry methods where negative ions are detected. Similarly, 'operating in positive ion mode' refers to those mass spectrometry methods where positive ions are detected.

"The term 'desorption' as used herein refers to the removal of an analyte from a surface and/or the entry of an analyte into a gaseous phase.
"The term 'about' as used herein in reference to quantitative measurements, refers to the indicated value plus or minus 10%.

Patent Issued for Methods of Isolating Distinct Pancreatic Cell Types (USPTO 9526749)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- According to news reporting originating from Alexandria, Virginia, by NewsRx journalists, a patent by the inventors Walker, Michael D. (Rehovot, IL); Soen, Yoav (Rehovot, IL); Sharivkin, Revital (Rehovot, IL), filed on February 20, 2015, was published online on December 27, 2016.

The assignee for this patent, patent number 9526749, is Yeda Research and Development Co. Ltd. (Rehovot, IL).

Reporters obtained the following quote from the background information supplied by the inventors: "Beta cells of the mature functional pancreas regulate metabolic homeostasis by controlled secretion of insulin. Impaired beta cell function and the resulting insufficient secretion of insulin, lead to persistently elevated levels of blood glucose, the hallmark of diabetes.

"Type 1 diabetes (T1D, also known as insulin dependent diabetes mellitus, IDDM) is an autoimmune disease that results in the destruction of the beta-cells in the pancreas. The collapse of glucose homeostasis and clinical manifestation of the disease is thought to occur only after 80-90% of pancreatic beta cells have been inactivated by the immune response. Incipient diabetes can be diagnosed by the detection of immunological markers of beta cell autoimmunity only after the onset of the autoimmune process.

"Type 2 Diabetes (T2D, formerly non-insulin-dependent diabetes mellitus, NIDDM, or adult-onset diabetes) is the most common form of diabetes, accounting for 90% of cases of diabetes. It is a metabolic disorder that is characterized by high blood glucose in the context of relative insulin resistance and insulin deficiency. Obesity is the primary cause of T2D in people who are genetically predisposed to the disease. Type 2 diabetes is initially managed by increasing exercise and dietary modification. If blood sugars are not lowered by these measures, medications such as metformin or insulin may be needed.

"Current treatments for diabetes are problematic and do not eliminate many of the long term complications associated with the disease. Consequently, there is great interest in developing improved treatments for diabetes.

"The adult pancreas is composed of endocrine and exocrine cell populations. The
endocrine cells are located within the islets of Langerhans, comprising cell-types of discrete functionalities (e.g. alpha cells producing glucagon, beta cells producing insulin, delta cells producing somatostatin etc.). In addition to the heterogeneity of the islets themselves, islet preparations are often contaminated by varying fractions of exocrine cells (including acinar cells, characterized by hydrolytic enzymes e.g. trypsin, chymotrypsin, amylase, lipase; and duct cells (Cleveland et al. 2012)) and even non-pancreatic cells. Pancreatic beta cells regulate metabolic homeostasis by controlled secretion of insulin; impaired beta cell function leads to persistently elevated levels of blood glucose, the hallmark of diabetes. Transplantation of functional pancreatic beta cells is one of the most promising approaches towards curing diabetes (Shapiro et al. 2000, N Engl J Med 343(4): 230-238; Serup et al. 2001, Bmj 322(7277): 29-32), but is currently limited by a severe shortage of donor tissue. This has motivated approaches capable of in vitro generation of functional insulin-producing cells (Kroon et al. 2008, Nat Biotechnol 26(4): 443-452; Russ et al. 2011, PLoS One 6(9): e25566). However, the lack of cell type-specific surface markers is a major obstacle for isolation of relevant cells.

"The ongoing world-wide epidemic of diabetes emphasizes the urgent need for improved diabetes treatments such as cell based therapies, hence the enormous interest in hESCs-derived pancreatic precursors. Recent results have demonstrated the potential of hESC-derived precursors to produce insulin in vivo (Kroon et al., Nat Biotechnol. 2008, 26,4, 443-52); yet the protocols are very inefficient and yield highly heterogeneous populations. Therefore, any future clinical use would likely require prospective identification and generation of precursor populations with higher fidelity.

"One approach is to generate beta cells in vitro from human embryonic stem cells (hESCs). hESCs are pluripotent cells, capable of generating every cell of the body. Since their initial derivation, hopes have been high that these cells might represent a source of unlimited numbers of beta cells, or beta cell progenitors for transplantation to diabetics. Another potential source is based on in vitro expansion of adult beta cells. Such expansion is accompanied by loss of beta cell markers and requires re-differentiation procedures to restore insulin expression (Russ et al., Diabetes. 2008, 57, 1575-83; Russ et al., PLoS One. 2011, 6, 9, e25566). Another serious impediment to cell replacement therapy is the current lack of cell surface markers selective for pancreatic cell subtypes.

"Current methods for identification of cell surface markers are based on flow cytometry, analysis of gene expression patterns and immunostaining. Higher throughput proteomics approaches based on antibody arrays, have also been used for profiling cell surface markers (Ko et al. 2005, Biomaterials 26(23): 4882-4891) and for discriminating cell populations based on differentially expressed markers (Sharivkin et al. Molecular & cellular proteomics 2012, 11(9): 586-595; and Belov et al. Cancer Res. 2001, 61, 4483-4489). Sharivkin et al. and Belov et al. have used antibody array procedures to screen for potential cell type-specific surface markers for human endoderm progenitors and leukemias, respectively. Although these platforms are very efficient for probing cell surface markers, they do not reveal association of specific markers with a particular function.

"Beta cell specific surface markers may facilitate identification and characterization of embryonic beta cell progenitors as well as purification of homogeneous insulin-producing cells from cultures derived from hESCs or re-differentiated beta cells. They may also allow isolation of adult beta cells, thus contributing to future diagnostic applications. One cell surface marker which might be selective for human beta cells is TMEM27. While antibodies were recently raised against this antigen (Vats et al. 2012, Diabetologia 55(9): 2407-2416), it is still unclear if they can be used to purify beta cells by flow cytometry or other methods.

"A variety of techniques have been previously employed in an attempt to isolate pancreatic beta cells. These include: genetic labeling (Meyer et al., Diabetes. 1998, 47, 1974-
1977), Newport green dye labeling (Łukowiak B et al., J Histochem Cytochem. 2001, 49, 519-528), elimination of duct cells (Banerjee and Otonkoski 2009, Diabetologia 52(4): 621-625), and the generation of hybridoma-derived antibodies which can enrich for different endocrine and non-endocrine cell types (Dorrell et al., Stem Cell Res. 2008, 1, 183-194). None of these techniques, however, relies on beta cell-specific surface markers and the isolated cell populations still exhibit an unknown degree of heterogeneity. The same lack of marker information applies to other endocrine subsets in human pancreas (i.e. alpha cells, delta cells etc.).

"There is an unmet need for robust screening procedures capable of identifying markers designating cells of desired type or function. Since tissue samples are often limited in quantity and availability, such procedures should permit functional analysis of multiple markers in parallel using small numbers of cells. Specifically, there is an unmet need for isolating insulin-producing beta cells within pancreatic tissue, for diagnostic and therapeutic uses in diabetes and other pancreatic-related disorders."

In addition to obtaining background information on this patent, NewsRx editors also obtained the inventors’ summary information for this patent: "The present invention provides methods of isolation of specific populations of cells using newly identified markers and selection means. More specifically, the present invention provides efficient tag-free isolation of pancreatic cell subtypes using specific cell surface markers.

"The present invention further provides novel combinations of cell markers suitable for identifying or enriching distinct cell populations, particular distinct cell subtypes within human islets of Langerhans. Uses of the markers and of the isolated cells in diagnosis and treatment of diabetes and other pancreatic disorders are also provided, as well as methods of identifying markers for improvement of purification of beta cells from pancreatic tissue.

"Pancreatic beta cell specific surface markers are of particular interest as they may facilitate purification of mature, functional insulin-producing beta cells suitable for transplantation and/or for diagnostic applications. These markers may also be used for isolation of pluripotent or partially differentiated beta cell progenitors which may be used as an abundant source of beta cells for diabetes cell replacement therapy.

"It is now disclosed for the first time, using antibody array procedures that certain cell-surface markers, not previously identified in connection with pancreatic cells or with diabetes, are consistently expressed in human islets. These markers were utilized to fractionate distinct cell populations from human islets of Langerhans and to tag-free isolate enriched populations of insulin-producing beta cells from the tissue containing other types of cells.

"The present invention thus provides, according to one aspect, a method of isolating an enriched population of at least one distinct type of pancreatic cells from a heterogeneous population of cells, comprising sorting the cells using a combination of at least two cell-surface markers relevant to the cell type to be isolated.

"According to some embodiments the heterogeneous population of cells is selected from the group consisting of cells recovered or extracted from pancreatic tissue, committed lineages of stem cells and cultures of differentiated stem cells.

"According to various embodiments, the invention provides a method of isolating at least one distinct type of cells, wherein the at least one cell-type is selected from the group consisting of: beta cells (insulin secreting cells), delta cells (somatostatin secreting cells), alpha cells (glucagon secreting cells) and exocrine cells (trypsin secreting cells). Each possibility represents a separate embodiment of the invention.

"According to some specific embodiments, the invention provides methods of isolating beta cells or beta cell progenitors.
"The present invention provides, according to some embodiments, a method of isolating an enriched population of at least one distinct type of pancreatic cells from a heterogeneous population of cells selected from the group consisting of cells recovered or extracted from pancreatic tissue, committed lineages of stem cells and cultures of differentiated stem cells, comprising sorting the cells using a combination of at least two cell-surface markers relevant to the cell type to be isolated, wherein the at least one distinct type of cells is selected from the group consisting of: beta cells and delta cells, and wherein one cell-surface marker is CD9.

"According to some embodiments, the at least one distinct type of cells is selected from the group consisting of: beta cells and delta cells, and wherein a first cell marker is CD9.

"According to some embodiments, the beta cells are enriched for using positive sorting or selection with the cell-surface marker CD9 (NP_001760.1, human species).

"According to some embodiments, the cell surface marker CD9 is the first marker used for selection.

"According to some embodiments, the beta cells are enriched for using positive selection with a combination of the cell-surface markers CD9 and CD56.

"According to a specific embodiment, the CD56 is NP_000606.3.

"According to yet other embodiments, the beta cells are isolated using a combination of the cell-surface markers CD9 and EGFR, wherein CD9 is used for positive selection and EGFR is used for negative selection.

"According to some embodiments, the EGFR cells surface is NP_005219.2.

"According to yet other embodiments, the beta cells are isolated using positive selections with combination of the cell-surface markers CD9 and CD56 and further selection with at least one additional cell-surface marker.

"According to some embodiments, the at least one additional cell-surface marker is selected from the group consisting of: CD4, CD73, CD87, CCR4, CD165, CD85J, CD221, CD153 (CD30L), CD142, CD134, ITGB7, CD68, WNT16, CD18, CD6, CD77, CD61, and CD32. Each possibility represents a separate embodiment of the invention.

"According to some embodiments, at least one additional cell-surface marker is selected from the group consisting of: CD4 (NP_000607.1), CD73 (NP_001191742.1), CD87 (NP_002650.1), CCR4 (NP_005499.1), CD165 (Gene ID 23449), CD85J (NP_001075106.1), CD221 (NP_000866.1), CD153 (CD30L) (NP_001235.1), CD142 (NP_001171567.1), CD134 (NP_003318.1), ITGB7 (NP_000880.1), CD68 (NP_001035148.1), WNT16 (NP_057171.2), CD18 (NP_000202.2), CD6 (NP_001241679.1), CD77 (NP_059132.1), CD61 (NP_000203.2), and CD32 (NP_001002273.1). Each possibility represents a separate embodiment of the invention.

"According to yet other embodiments, the beta cells are isolated using a combination of at least two cell-surface markers wherein one marker is CD9 and at least one other marker is selected from the group consisting of: CD56 (NP_000606.3), EGFR (NP_005219.2), CD4 (NP_000607.1), CD73 (NP_001191742.1), CD87 (NP_002650.1), CCR4 (NP_005499.1), CD165 (Gene ID 23449), CD85J (NP_001075106.1), CD221 (NP_000866.1), CD153 (CD30L) (NP_001235.1), CD142 (NP_001171567.1), CD134 (NP_003318.1), ITGB7 (NP_000880.1), CD68 (NP_001035148.1), WNT16 (NP_057171.2), CD18 (NP_000202.2), CD6 (NP_001241679.1), CD77 (NP_059132.1), CD61 (NP_000203.2), and CD32 (NP_001002273.1). Each possibility represents a separate embodiment of the invention.

"According to some embodiments, the isolated beta cells are mature, functional insulin-producing cells.
According to some embodiments, the beta cells are isolated from extracts of human islets of Langerhans.

According to some embodiments, beta cells are isolated from committed lineages of stem cells and cultures of differentiated stem cells.

According to yet other embodiments, beta cells or beta cell progenitors are isolated from cultures derived from human stem cells.

According to some embodiments beta cells or beta cell progenitors are isolated from populations of human induced pluripotent stem cells.

According to other embodiments beta cells or beta cell progenitors are isolated from human adult stem cells.

According to yet other embodiments, beta cells or beta cell progenitors are isolated from human embryonic stem cells obtained by methods that do not involve the destruction of embryos.

According to other embodiments, isolated cells are selected from the group consisting of: insulin-secreting cells, somatostatin-secreting cells, trypsin-secreting cells and glucagon secreting cells.

According to some embodiments, a method for isolating glucagon-producing alpha cells is disclosed comprising using a combination of the cell surface markers CD9 and CD56 wherein the CD9 marker is used for negative selection and the CD56 is used for positive selection.

According to other embodiments, a method for isolating trypsin-producing acinar cells is disclosed comprising using a combination of the cell surface markers CD9 and CD56, wherein both markers are used for negative selection.

According to a specific embodiment the method of isolating an enriched population of at least one distinct type of pancreatic cells from a heterogeneous population of cells comprises the steps: i. obtaining a heterogeneous population of cells selected from the group consisting of cells recovered or extracted from pancreatic tissue, committed lineages of stem cells and cultures of differentiated stem cells; ii. exposing the cells obtained in (i) to a probe capable of identifying CD9+ cells and to at least one additional probe; iii. isolating cells expressing CD9 and the additional probe by sorting of cells, thereby isolating an enriched population of at least one distinct cell type selected from the group consisting of: beta cells and delta cells.

According to some embodiments, the at least one additional probe is selected from the group consisting of: CD56 (NP_000606.3), CD4 (NP_000607.1), CD73 (NP_001191742.1), CD87 (NP_002650.1), CCR4 (NP_005499.1), CD165 (Gene ID 23449), CD85J (NP_001075106.1), CD221 (NP_000866.1), CD153 (CD30L) (NP_001235.1), CD142 (NP_001171567.1), CD134 (NP_003318.1), ITGB7 (NP_000880.1), CD68 (NP_001035148.1), WNT16 (NP_057171.2), CD18 (NP_000202.2), CD6 (NP_001241679.1), CD77 (NP_059132.1), CD61 (NP_000203.2), and CD32 (NP_001002273.1). Each possibility represents a separate embodiment of the invention.

According to some embodiments, the at least one additional probe is selected from the group consisting of: CD56 (NP_000606.3), CD4 (NP_000607.1), CD73 (NP_001191742.1), CD87 (NP_002650.1), CCR4 (NP_005499.1), CD165 (Gene ID 23449), CD85J (NP_001075106.1), CD221 (NP_000866.1), CD153 (CD30L) (NP_001235.1), CD142 (NP_001171567.1), CD134 (NP_003318.1), ITGB7 (NP_000880.1), CD68 (NP_001035148.1), WNT16 (NP_057171.2), CD18 (NP_000202.2), CD6 (NP_001241679.1), CD77 (NP_059132.1), CD61 (NP_000203.2), and CD32 (NP_001002273.1). Each possibility represents a separate embodiment of the invention.

According to a specific embodiment, the at least one additional probe is CD56 used for positive selection of cells.

According to another specific embodiment, the at least one additional probe is
Epidermal Growth Factor Receptor (EGFR), used for negative selection of cells.

"According to some embodiments, the EGFR is NP_005219.2, NP_958439.1, NP_958440.1, or NP_958441.1. Each possibility represents a separate embodiment of the invention.

"According to some embodiments, purified cells of iii are subject to additional iterations comprising steps (ii)-(iii) with additional probes used for positive or negative selection of cells.

"According to some embodiments, the sorting methodology is fluorescence activated cell sorting (FACS).

"According to some embodiments, the distinct cell types are isolated from human pancreatic tissue.

"According to a specific embodiment, the cells are isolated from human islets of Langerhans.

"According to some embodiments, at least one cell-surface marker is used for positive or negative sorting of cells according to any of the methods described above, for isolating at least one distinct cell type of cells from human islets of Langerhans, wherein the at least one cell-surface marker is selected from the group consisting of: CD104, (Integrin, beta 4: AAI43739.1); CD11A, (integrin alpha-L isoform b precursor: NP_001107852.1); CD11B/MAC1, (integrin alpha-M isoform 2: NP_000623.2); CD11C, (integrin alpha-X: NP_000878.2); CD135, (Fms-related tyrosine kinase 3: AAI44041.1); CD140B, (Platelet-derived growth factor receptor, beta polypeptide: AAH32224.1); CD142, (Coagulation factor III/thromboplastin, tissue factor: AAH11029.1); CD146, (cell surface glycoprotein MUC18: NP_006491.2); CD147, (basigin: NP_940992.1); CD15, (alpha-(1,3)-fucosyltransferase: NP_002024.1); CD164, (CD164 antigen, salomucin, isoform CRA_: EAW48353.1); CD166, (Activated leukocyte cell adhesion molecule: AAH37097.1); CD177, (glycoprotein NB1: CAC83758.1); CD197, (C-C chemokine receptor type 7: NP_001829.1); CD221 3b7, (insulin-like growth factor 1 receptor: NP_000866.1); CD226, (T-cell immunoreceptor with Ig and ITIM: NP_776160.2); CD271, (tumor necrosis factor receptor superfamily member 16: NP_002498.1); CD28, (T-cell-specific surface glycoprotein isoform 2: NP_001230006.1); CD282, (toll-like receptor 2: NP_003255.2); CD29, (integrin beta-1 isoform 1A: NP_002202.2); CD3, (T-cell surface glycoprotein CD3 gamma chain: NP_000664.1); CD36, (antigen CD36: AAA58413.1); CD42b, (platelet glycoprotein 1b alpha chain: NP_000164.5); CD44, (cell surface glycoprotein CD44: AAB13625.1); CD45RB (interleukin-27 subunit alpha precursor: NP_663634.2); CD47, (leukocyte surface antigen CD47 isoform 2: NP_942088.1); CD49b, (integrin alpha-2: NP_002194.2); CD49E, (integrin alpha 5/fibronectin receptor, alpha polypeptide: AAH08786.1); CD49F, (Integrin, alpha 6: AAI36457.1); CD50, (Intercellular adhesion molecule 3: AAH58903.1); CD53, (leukocyte surface antigen CD53: NP_000551.1); CD54, (Intercellular adhesion molecule 1: AAH15969.1); CD55, (CD55 antigen, decay accelerating factor for complement/Cromer blood group, isoform CRA_i: EAW93497.1); CD57, (galactosylgalactosylxylosylprotein 3-beta-glucuronosyltransferase 1: NP_061114.2); CD59, (CD59 glycoprotein: NP_976076.1); CD61, (Integrin, beta 3/platelet glycoprotein Ma, antigen CD61: AAI27668.1); CD63, (CD63 antigen isoform A: NP_001244320.1); CD66, (integrin beta-2: NP_000202.2); CD66B, (Carcinoembryonic antigen-related cell adhesion molecule 8: AAH26263.1); CD66C, (Carcinoembryonic antigen-related cell adhesion molecule 6: AAH05008.1); CD71, (transferrin receptor protein 1: NP_001121620.1); CD81, (CD81 antigen/target of antiproliferative antibody 1: EAX02508.1); CD9, (CD9 antigen: NP_001760.1); CD90, (Thy-1 cell surface antigen: AAH65559.1); CD97, (CD97 antigen, isoform CRA_b: EAW84413.1); CD98, (cell-surface antigen heavy chain isoform c: NP_002385.3); CD99, (CD99 antigen isoform X24: XP_005274856.1); C-ERB-2, (protooncogene protein:
AAA35808.1); CLIP, (CAP-Gly domain-containing linker protein 1 isoform a: NP_002947.1); CXCXR4, (C-X-C chemokine receptor type 4 isoform a: NP_001008540.1); EGFR, (epidermal growth factor receptor variant A: ADL28125.1); HLA-A2, (MHC class I antigen HLA-A2: AAA87076.1); HLA-ABC, (MHC class I antigen, partial: AAA59602.1); HLA-DR, (MHC class II antigen: ADM15723.1); Hematopoietic progenitor cell, (KS1/4, epithelial cell adhesion: NP_002345.2); LTBR, (lymphotoxin beta receptor/TNFR superfamily, member 3: EAW88802.1); P-Glycoprotein: AAA59575.1; SCARB1, (scavenger receptor class B member 1: NP_005496.4); TROP-2 (integrin beta-1 isoform 1A: NP_596867.1); B2-microglobulin: AAA51811.1. Variants of said cell-surface markers, having different accession numbers are also included in the scope of the present invention. Each possibility represents a separate embodiment of the invention.

"According to some embodiments, the distinct cell-types are selected from the group consisting of: beta cells, delta cells, alpha cells and exocrine cells. Each possibility represents a separate embodiment of the invention.

"According to some embodiments the distinct cell type is beta cells or beta cell progenitors.

"Uses of the isolated cells for diagnosis and therapy, as well as for research, are also within the scope of the present invention.

"According to some embodiments, beta cells or beta cell progenitors, isolated according to the present invention are used for transplantation to a mammalian subject for prevention or treatment of diabetes.

"According to some embodiments, mature, functional insulin-producing beta cells, isolated according to the present invention are used for transplantation.

"According to other embodiments, beta cell progenitors, isolated from cultures derived from hESCs or re-differentiated beta cells, are used for transplantation.

"According to some embodiments, the mammalian subject is a human subject.

"A method of prevention or treatment of diabetes is also disclosed, comprising transplantation of to a mammalian subject in need thereof of a population of beta cells or beta cell progenitors isolated according to the methods of the present invention.

"According to some embodiments the mammalian subject is a human subject.

"According to some embodiments the population of beta cells comprises mature, functional insulin-producing beta cells.

"According to other embodiments, the beta cell progenitors were isolated from culture derived from hESCs or re-differentiated beta cells.

"According to other embodiments, the isolated cells are used for diagnostic applications or for development of diagnostic tools.

"According to some embodiments isolated cells according to the present invention are used to quantify the number and state of beta cells in subjects in need thereof, thus allowing detection of diabetes prior to the onset of hyperglycemia symptoms.

"According to other embodiments, embryonic stem cells or partially differentiated stem cells or beta cell progenitors isolated according to the present invention are used as a source of beta cells for diabetes cell replacement therapy.

"According to some embodiments, said embryonic stem cells comprise human cells obtained only by methods that that do not involve the destruction of embryos.

"According to yet other embodiments, isolated beta cells are used in research to study differentiation pathways that leads embryonic stem cells to become insulin-producing beta
"The present invention also provides a functional screening method for identifying cell-surface marker combinations suitable of purifying or enriching a population of cells within heterogeneous populations of cells, the method comprises the steps of: i. obtaining a heterogeneous population of cells; ii. applying the heterogeneous cells of (i) to an array comprising antibodies against cell-surface markers, to allow binding of cells to the array; iii. immunostaining the bound cells of (ii) with antibodies specific for a functional marker thereby identifying antibody stained loci enriched for functional cells; and iv. determining the cell-surface markers at the loci enriched for the functional cells of (iii).

"According to some embodiments, the method comprises fixing and permeabilizing the cells before immunostaining of (iii).

"According to some embodiments, cells obtained in (i) are isolated based on a relevant marker, before performing step (ii).

"According to some specific embodiments, isolation is performed by fluorescence activated cell sorting (FACS).

"According to some embodiments, marker combination is used for improving the degree of purity of cell isolation or for fractionation of heterogeneous cellular systems.

"According to some embodiments the functional screening method is used for identifying cell-surface marker combinations suitable of purifying enriched population of insulin-producing beta cells within pancreatic tissue, wherein the method comprises the following steps: i. obtaining a heterologous population of cells selected from the group consisting of cells recovered or extracted from pancreatic tissue, committed lineages of stem cells and cultures of differentiated stem cells; ii. isolating CD9+ cells from the cells obtained in (i); iii. applying the CD9+ cells of (ii) to an array comprising antibodies against cell-surface markers; iv. immunostaining the bound cells of (iii) with antibodies against insulin and somatostatin thereby identifying antibody stained loci enriched for beta and delta cells; and v. determining the cell-surface markers of the loci enriched for beta cells in (iv).

"According to other embodiments, the functional screening method is used for identifying cell-surface markers suitable of purifying enriched populations of cells selected from the group consisting of: pancreatic exocrine cells, pancreatic endocrine cells such as beta cells, alpha cells and non-pancreatic cells such as blood cells.

"According to some specific embodiments, the functional screening method is used for identifying further cell-surface markers suitable of purifying enriched populations of cells selected from the group consisting of: insulin-secreting cells, somatostatin-secreting cells, trypsin-secreting cells and glucagon secreting cells. Each possibility represents a separate embodiment of the invention.

"Further embodiments and the full scope of applicability of the present invention will become apparent from the detailed description given hereinafter. However, it should be understood that the detailed description and specific examples, while indicating preferred embodiments of the invention, are given by way of illustration only, since various changes and modifications within the spirit and scope of the invention will become apparent to those skilled in the art from this detailed description."

CARDIAC DIMENSIONS PTY. LTD.

Patent Issued for Mitral Valve Annuloplasty Device with Twisted Anchor (USPTO 9526616)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A patent by the inventors Nieminen, Gregory (Bothell, WA); Thaler, Carly A. (Seattle, WA), filed on July 17, 2006, was published online on December 27, 2016, according to news reporting originating from Alexandria, Virginia, by NewsRx correspondents.

Patent number 9526616 is assigned to CARDIAC DIMENSIONS PTY. LTD. (Kirkland, WA).

The following quote was obtained by the news editors from the background information supplied by the inventors: "This invention relates generally to devices and methods for shaping tissue by deploying one or more devices in body lumens adjacent to the tissue. One particular application of the invention relates to a treatment for mitral valve regurgitation through deployment of a tissue shaping device in the patient's coronary sinus or great cardiac vein.

"The mitral valve is a portion of the heart that is located between the chambers of the left atrium and the left ventricle. When the left ventricle contracts to pump blood throughout the body, the mitral valve closes to prevent the blood being pumped back into the left atrium. In some patients, whether due to genetic malformation, disease or injury, the mitral valve fails to close properly causing a condition known as regurgitation, whereby blood is pumped into the atrium upon each contraction of the heart muscle. Regurgitation is a serious, often rapidly deteriorating, condition that reduces circulatory efficiency and must be corrected.

"Two of the more common techniques for restoring the function of a damaged mitral valve are to surgically replace the valve with a mechanical valve or to suture a flexible ring around the valve to support it. Each of these procedures is highly invasive because access to the heart is obtained through an opening in the patient's chest. Patients with mitral valve regurgitation are often relatively frail thereby increasing the risks associated with such an operation. A device to perform mitral valve annuloplasty is therefore needed that can be implanted percutaneously without opening the chest wall."

In addition to the background information obtained for this patent, NewsRx journalists also obtained the inventors' summary information for this patent: "One aspect of the invention provides a tissue shaping device (such as a percutaneous mitral valve annuloplasty device) adapted to be deployed in a vessel to reshape tissue adjacent the vessel. The device comprises a first anchor and a second anchor adapted to be deployed by a catheter to engage a vessel wall, wherein the first anchor includes a shaping feature adapted to resist the compression of a first part of the first anchor and resist the expansion of a second part of the first anchor in response to a compressive force on the first part, and a support structure disposed between and operatively connecting the first anchor and the second anchor. In some embodiments the
anchors are adapted to engage a coronary sinus.

"In some embodiments the first anchor comprises two entwisted wire segments, possibly arranged in a figure-8 configuration having first and second arms coupled at least one coupling point (formed from, e.g., entwisted wire) as the shaping feature. In some embodiments, the coupling point is substantially at an apex of the first anchor when the anchor is in its deployed configuration. In some embodiments, the anchor's width is greater than its height in its deployed configuration.

"In some embodiments the device also includes an anchor lock adapted to lock the first anchor and/or the second anchor in an expanded configuration. In some embodiments the device has a coupler, which may include a tether and a hitch wire, which is adapted to couple the device to a delivery tool. In some embodiments the coupler is further adapted to release the device from the delivery tool. In some embodiments the device is adapted to be recaptured by the catheter.

"One aspect of the invention is a method of performing mitral valve annuloplasty on a patient's heart. The method comprises percutaneously delivering a mitral valve annuloplasty device to a vessel in the patient's heart, where the device comprises first and second anchors and a support structure disposed between and operatively connecting the first and second anchors, anchoring the first anchor of the mitral valve annuloplasty device in the vessel, resisting compression of a first part of the first anchor and resisting expansion of a second part of the first anchor in response to a compressive force on the first part, and anchoring the second anchor of the mitral valve annuloplasty device.

"In some embodiments the first anchoring step comprises expanding the first anchor from a delivery configuration to a deployed configuration in which the first anchor engages the coronary sinus. In some embodiments, the anchor's width in the deployed configuration is greater than its height. In some embodiments the method includes locking the first anchor in the deployed configuration.

"In some embodiments of the method the second anchoring step includes expanding the second anchor from a delivery configuration to a deployed configuration in which the second anchor engages the coronary sinus. In some embodiments the method includes locking the second anchor in the deployed configuration.

"In some embodiments the method includes capturing the first anchor and/or the second anchor within the catheter after the first anchoring step. The capturing step may include advancing a catheter distally over the anchor to place the anchor inside the catheter in the delivery configuration.

"In some embodiments the method includes applying a proximally directed force on the mitral valve annuloplasty device after the first anchoring step. In some embodiments the method includes uncoupling the device from a delivery tool after the second anchoring step. The uncoupling may comprise releasing a hitch wire from the device and removing a tether from the device."

Our reports deliver fact-based news of research and discoveries from around the
Patent Issued for N-BOC-Dendrimers and Their Conjugates (USPTO 9526795)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- According to news reporting originating from Alexandria, Virginia, by NewsRx journalists, a patent by the inventor Van, Sang (San Diego, CA), filed on August 27, 2013, was published online on December 27, 2016.

The assignee for this patent, patent number 9526795, is Annam Biosciences, LLC (San Diego, CA).

Reporters obtained the following quote from the background information supplied by the inventors: "Field of the Invention
"The present invention relates to a composition for enhancing drug delivery, imaging resolution and/or affinity. More specifically, the present invention relates to a composition comprising mono-protected Boc-dendrimers and their conjugates.

"Description of the Related Art
"Cancer continues to be a significant health problem in our society and the number of cases per year is increasing as the population ages. Cancer is likely to impact 1 in 3 of us. According to the American Cancer Society's annual cancer statistics report, 'Cancer Statistics, 2013,' 1.6 million Americans will be diagnosed with invasive cancer in 2013, and 0.5 million Americans will die from cancer this year. Cytotoxic agents are currently the major chemotherapeutic treatment modality for most types of cancer. However, current cancer chemotherapeutic treatments remain inherently toxic and have severe side effects.

"The role of magnetic resonance imaging (MRI) in the diagnosis and evaluation of cancer continues to evolve and become important because it is non-invasive and non-irradiating. See Bulte et al. 'Magnetic resonance microscopy and histology of the CNS,' Trends in Biotechnology, 2002, 20, S24-S28. Although images of tissues can be obtained, contrast agents significantly improve MRI resolution. A current FDA-approved MRI contrast agent is Gd-DTPA, commercialized as MAGNEVIST.RTM. gadopentetate dimeglumine Caravan et al. reported other Gd-chelates that are under development, see Caravan et al. 'Gadolinium(III) Chelates as MRI Contrast Agents: Structure, Dynamics, and Applications,' Chem. Rev. 1999, 99, 2293-2352. Similar to chemotherapeutic agents, currently approved contrast agents are also nonselective.

"The folate-receptor (FR) is overexpressed on a number of major malignancies including adenocarcinoma of the lung and ovarian cancer, see Pribble P, Edelman M J. EC145: a novel targeted agent for adenocarcinoma of the lung. Expert Opin Investig Drugs. 2012; 21 (5):755-61. However, relatively few small molecule drug conjugates with folic acid have been investigated since Dr. Fuchs's group at University of Purdue reported that Taxol-folic acid conjugates failed to demonstrate selective killing of folate receptor-expressing tumor cells in vitro or enhanced in vivo antitumor activity over Taxol when administered in an equimolar quantity formulated in the same injection vehicle. See Lee J W, Lu J Y, Low P S, Fuchs P L. Synthesis and evaluation of taxol-folic acid conjugates as targeted antineoplastics. Bioorg Med Chem. 2002, 10, 2397-414.

"U.S. Pat. No. 7,128,893 disclosed vitamin-targeted imaging agents coupled via a
divalent linker (vitamin-linker-imaging agent); U.S. Pat. No. 7,601,332 disclosed a vitamin-targeted drug delivery conjugate via a divalent linker (vitamin-linker-drug).

"Relatively few multi-valent linker platforms have been reported. See the following U.S. patents: U.S. Pat. No. 4,435,548; U.S. Pat. No. 4,507,466; U.S. Pat. No. 4,558,120; U.S. Pat. No. 4,568,737; U.S. Pat. No. 4,587,329; U.S. Pat. No. 4,871,779; U.S. Pat. No. 4,631,337. U.S. Pat. No. 5,714,166, disclosed bioactive and/or targeted dendrimer conjugates. However, when a drug is conjugated to a dendrimer and followed by conjugation of a vitamin, a number of species result because it is difficult to control the location and the amount of the drug and the vitamin on the dendrimer. See Majoros I J, Myc A, Thomas T, Mehta C B, Baker J R. PAMAM Dendrimer-Based Multifunctional Conjugate for Cancer Therapy: Synthesis, Characterization, and Functionality. Biomacromolecules 2006, 7, 572-579.

"Despite billions of dollars poured every year into developing better treatment options, there is an urgent need for safer and more effective therapies."

In addition to obtaining background information on this patent, NewsRx editors also obtained the inventor's summary information for this patent: "An embodiment provides an asymmetrical dendritic compound represented by the Formula (I): R.sup.1--X.sup.1--NH-L-Gn-(NH--X.sup.2--R.sup.2).sub.m (I)

"wherein: Gn is a dendritic PAMAM group, having a core group and a shell group, for which n is zero or an integer in the range of 1 to 3 that specifies the generation of the dendritic PAMAM group; R.sup.1--X.sup.1--NH-L is a group attached to the core group, wherein R.sup.1 is selected from H, NH.sub.2NH, CO.sub.2C(CH.sub.3).sub.3, a maleimide group, a targeting ligand, a drug, an imaging agent; X.sup.1 is absent or selected from C.sub.1-4 alkylene and C.sub.1-8 alkyleneoxide; and L is absent or selected from C.sub.1-4 alkylene and C.sub.1-8 alkyleneoxide; (NH--X.sup.2--R.sup.2).sub.m is a terminal group attached to the shell group, wherein m is 2, 4, 8 or 16 and specifies the number of the attached NH--X.sup.2--R.sup.2 terminal groups; each X.sup.2 is independently selected from C.sub.1-4 alkylene, succinimidyl, C.sub.1-8 alkyleneoxide, C.sub.1-4 alkylene, C.sub.1-8 alkyleneoxide, C.sub.1-4 alkylene, C.sub.1-8 alkyleneoxide, C.sub.1-4 alkylene, C.sub.1-8 alkyleneoxide, C.sub.1-4 alkylene, C.sub.1-8 alkyleneoxide, NH--C.sub.1-4 alkylene-NH, C.sub.1-8 alkylene-NH, C.sub.1-4 alkylene-NH, C.sub.1-8 alkylene-NH, and each R.sup.2 is independently selected from H, hydroxyl, a maleimide group, a succinimide group, a targeting ligand, a drug, an imaging agent; each a is independently an integer in the range of 1 to 4; and each R.sup.2 is different from R.sup.1.

"Another embodiment provides an asymmetrical dendritic compound as described herein that is represented by the Formulae (Ia), (Ib), (Ic) or (Id) as follows:

"##STR00001## ##STR00002##

"Another embodiment provides an asymmetrical dendritic compound as described herein in which R.sup.1 is selected from the group consisting of H, CO.sub.2C(CH.sub.3).sub.3, and maleimide.

"Another embodiment provides an asymmetrical dendritic compound as described herein in which R.sup.2 comprises a targeting ligand.

"Another embodiment provides an asymmetrical dendritic compound as described herein in which the targeting ligand is selected from the group consisting of folic acid, mannose, anisamide, RGD peptide, NGR peptide, galactosamine, antibody, antibody fragment, and protein.

"Another embodiment provides an asymmetrical dendritic compound as described herein in which R.sup.2 comprises an imaging agent.

"Another embodiment provides an asymmetrical dendritic compound as described herein in which the imaging agent is selected from the group consisting of a Gadolinium (III)-
chelate, a Technetium(99m)-chelate, a Gallium-chelate, and a Thallium-chelate.

"Another embodiment provides an asymmetrical dendritic compound as described herein in which the imaging agent is selected from the group consisting of $^{64}$Cu diacetyl-bis(N.sup.4-methylthiosemicarbazone), $^{18}$F-fluorodeoxyglucose, 3'-deoxy-3'-(.$sup.18$F) fluorothymidine, and $^{18}$F-fluoromisonidazole.

"Another embodiment provides an asymmetrical dendritic compound as described herein in which R.sup.2 comprises a drug.

"Another embodiment provides a therapeutic agent represented by the Formula (I), wherein: Gn is a dendritic PAMAM group, having a core group and a shell group, for which n is zero or an integer in the range of 1 to 3 that specifies the generation of the dendritic PAMAM group; R.sup.1--X.sup.1--NH-L is a group attached to the core group, wherein R.sup.1 is selected from a targeting ligand, an anticancer drug, and an imaging agent; X.sup.1 is absent or selected from C(.dbd.O)(CH.sub.2).sub.aC(.dbd.O), C.sub.1-4 alkylene and C.sub.1-8 alkyleneoxide; and L is absent or selected from C.sub.1-4 alkylene and C.sub.1-4 alkyleneoxide; (NH--X.sup.2--R.sup.2).sub.m is a terminal group attached to the shell group, wherein m is 2, 4, 8 or 16 and specifies the number of the attached NH--X.sup.2--R.sup.2 terminal groups; each X.sup.2 is independently absent or a linker selected from C.sub.1-4 alkylene, succinimidyl, C.sub.1-8 alkyleneoxide, C(.dbd.O)(CH.sub.2).sub.aC(.dbd.O), C(.dbd.O)(CH.sub.2).sub.aC(.dbd.O)--NH--C.sub.1-4alkylene-NH, C(.dbd.O)(CH.sub.2).sub.aC(.dbd.O)--NH--C.sub.1-8alkyleneoxide-NH; each R.sup.2 is independently selected from a targeting ligand, an anticancer drug, and an imaging agent; and each a is independently an integer in the range of 1 to 4; and each R.sup.2 is different from R.sup.1.

"Another embodiment provides a therapeutic agent as described herein in which one of R.sup.1 and R.sup.2 comprises a targeting ligand and the other of R.sup.1 and R.sup.2 comprises an anticancer drug or an imaging agent.

"Another embodiment provides a therapeutic agent as described herein in which R.sup.1 comprises an anticancer drug.

"Another embodiment provides a therapeutic agent as described herein in which the anticancer drug is selected from the group consisting of doxorubicin, platinum, paclitaxel, docetaxel, combretastin A-4, vinblastine, vincristine, vinorelbine, camptothecin, SN-38, etoposide, teniposide, auristatin, calicheamicin, maytansinoid, and duocarmycin.

"Another embodiment provides a therapeutic agent as described herein in which R.sup.1 comprises an anticancer drug and R.sup.2 comprises a folic acid targeting ligand.

"Another embodiment provides a therapeutic agent as described herein in which the imaging agent is selected from the group consisting of a Gadolinium (III)-chelate, a Technetium (99m)-chelate, a Gallium-chelate, and a Thallium-chelate.

"Another embodiment provides a therapeutic agent as described herein in which the imaging agent is selected from the group consisting of $^{64}$Cu diacetyl-bis(N.sup.4-methylthiosemicarbazone), $^{18}$F-fluorodeoxyglucose, 3'-deoxy-3'-(.$sup.18$F) fluorothymidine, and $^{18}$F-fluoromisonidazole.

"Another embodiment provides a method of delivering a therapeutic agent to a cell, comprising contacting the cell with a therapeutic agent as described herein. In an embodiment, the contacting is conducted in vitro. In another embodiment, the contacting is conducted in vivo.

"Another embodiment provides a method of treating cancer, comprising identifying a
patient in need of cancer treatment and administering a therapeutically effective amount of a therapeutic agent as described herein.

"Another embodiment provides a therapeutic agent as described herein for use in the treatment of cancer.

"Another embodiment provides the use of a therapeutic agent as described in the manufacture of a medicament for the treatment of cancer.

"Some embodiments disclosed herein relate to a N-Boc-dendrimer. Other embodiments disclosed herein relate to N-Boc-dendrimer with generation 0 (G0). Other embodiments disclosed herein related to N-Boc-dendrimers with generations 1 (G1), 2 (G2), 3 (G3), and 4 (G4).

"Some embodiments of the compositions disclosed herein relate to N-Boc-dendrimer that can include two targeting ligands. The targeting ligand is selected from the group consisting of folic acid, mannose, anisamide, RGD peptide, NGR peptide, galactosamine, antibody, antibody fragments, and protein. Other embodiments of the compositions disclosed herein relate to N-Boc-dendrimer that can include four targeting ligands. Other embodiments of the compositions disclosed herein relate to N-Boc-dendrimer that can include eight targeting ligands. Other embodiments of the compositions disclosed herein relate to N-Boc-dendrimer that can include sixteen targeting ligands. Other embodiments of the compositions disclosed herein relate to N-Boc-dendrimer that can include thirty-two targeting ligands.

"Some embodiments of the compositions disclosed herein relate to dendrimer that can include an imaging agent and two targeting ligands. The imaging agent can be selected from optical imaging agent and magnetic resonance imaging, and the targeting ligand is selected from the group consisting of folic acid, mannose, anisamide, RGD peptide, NGR peptide, galactosamine, antibody, antibody fragments, and protein. Other embodiments of the compositions disclosed herein relate to dendrimer that can include an imaging agent and four targeting ligands. Other embodiments of the compositions disclosed herein relate to dendrimer that can include an imaging agent and sixteen targeting ligands. Other embodiments of the compositions disclosed herein relate to dendrimer that can include thirty-two targeting ligands.

"Some embodiments described herein relate to a method of imaging a tumor that can include administering an effective amount of a dendrimer that includes an imaging contrast agent and two targeting ligands described herein. The targeting ligand is selected from the group consisting of folic acid, mannose, anisamide, RGD peptide, NGR peptide, galactosamine,
antibody, antibody fragments, and protein. Other embodiments described herein relate to a method of imaging a tumor using a dendrimer that includes an imaging contrast agent and four targeting ligands. Still other embodiments described herein relate to a method of imaging a tumor using a dendrimer that includes an imaging contrast agent and eight targeting ligands. Still other embodiments described herein relate to a method of imaging a tumor using a dendrimer that includes an imaging contrast agent and sixteen and thirty-two targeting ligands.

"Some embodiments described herein relate to a method of treating a tumor that can include administering an effective amount of a dendrimer that includes a drug and two targeting ligands described herein. The targeting ligand is selected from the group consisting of folic acid, mannose, anisamide, RGD peptide, NGR peptide, galactosamine, antibody, antibody fragments, and protein. Other embodiments described herein relate to a method of treating a tumor using a dendrimer that includes a drug and four targeting ligands. Still other embodiments described herein relate to a method of treating a tumor using a dendrimer that includes a drug and eight targeting ligands. Still other embodiments described herein relate to a method of treating a tumor using a dendrimer that includes a drug and sixteen targeting ligands. Still other embodiments described herein relate to a method of treating a tumor using a dendrimer that includes a drug and thirty-two targeting ligands.

Another embodiment described herein relates to a method of making the dendrimer that includes an imaging agent with two targeting ligands, four targeting ligands, eight targeting ligands, sixteen, or thirty-two targeting ligands comprising the steps of at dissolving N-Boc-dendrimer described herein in an aprotic solvent (e.g. DMF, DCM, or DMSO), and coupling with two targeting ligands, four targeting ligands, eight targeting ligands, sixteen, or thirty-two targeting ligands; then deprotect the Boc protecting group-dendrimer-two targeting ligands, four targeting ligands, eight targeting ligands, sixteen, or thirty-two targeting ligands, respectively, with trifluoroacetic acid and follow with a coupling of an imaging agent.

Another embodiment described herein relates to a method of making the dendrimer that includes an imaging agent with two targeting ligands, four targeting ligands, eight targeting ligands, sixteen targeting ligands, thirty-two ligands comprising the steps of at dissolving N-Boc-dendrimer described herein in an aprotic solvent (e.g. DMF or DMSO), and coupling with two targeting ligands, four targeting ligands, eight targeting ligands, sixteen, or thirty-two targeting ligands; then deprotect the Boc protecting group-dendrimer-two targeting ligands, four targeting ligands, eight targeting ligands, sixteen, or thirty-two targeting ligands, respectively, with trifluoroacetic acid and follow with coupling of an anticancer drug. The drug is selected from the group consisting of doxorubicin, platinum, SN-38, paclitaxel, docetaxel, combretastatin A-4, vinblastine, vincristine, vinorelbine, camptothecin, etoposide, teniposide, auristatin, calicheamicin, maytansinoid, and duocarmycin. The targeting ligand is selected from the group consisting of folic acid, mannose, anisamide, RGD peptide, NGR peptide, galactosamine, antibody, antibody fragments, and protein.

Some embodiments of the compositions disclosed herein relate to dendrimer that can include a maleimide group and two anticancer drugs. For example, the drug is selected from a group of doxorubicin, platinum, SN-38, paclitaxel, docetaxel, combretastatin A-4, vinblastine, vincristine, vinorelbine, camptothecin, etoposide, teniposide, auristatin, calicheamicin, maytansinoid, and duocarmycin. The targeting ligand is selected from the group consisting of folic acid, mannose, anisamide, RGD peptide, NGR peptide, galactosamine, antibody, antibody fragments, and protein. Other embodiments of the compositions disclosed herein relate to dendrimer that can include a drug and four targeting ligands. Other embodiments of the compositions disclosed herein relate to dendrimer that can include a drug and eight targeting ligands. Other embodiments of the compositions disclosed herein relate to dendrimer that can include a drug and sixteen and thirty-two targeting ligands.
Another embodiment described herein relates to a method of making the dendrimer that includes a maleimide group and two anticancer drugs, four anticancer drugs, eight anticancer drugs, sixteen, or thirty-two anticancer drugs comprising the steps of at dissolving N-Boc-dendrimer described herein in an aprotic solvent (e.g. DMF, DCM, or DMSO), and coupling with two anticancer drugs, four anticancer drugs, six anticancer drugs, sixteen, or thirty-two anticancer drugs; then deprotect the Boc protecting group-dendrimer-two anticancer drugs, four anticancer drugs, six anticancer drugs, sixteen, or thirty-two anticancer drugs with trifluoroacetic acid (TFA) and follow with coupling of a maleimide group.

"These and other embodiments are described in greater detail below."

Savage River, Inc.

Patent Issued for Nutrient-Dense Meat Structured Protein Products (USPTO 9526267)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- From Alexandria, Virginia, NewsRx journalists report that a patent by the inventors Anderson, David (Agoura Hills, CA); Fuller, Justin (Columbia, MO); Geistlinger, Timothy (Oakland, CA), filed on April 15, 2015, was published online on December 27, 2016.

The patent's assignee for patent number 9526267 is Savage River, Inc. (El Segundo, CA).

News editors obtained the following quote from the background information supplied by the inventors: "A large number of individuals around the world follow vegetarian or vegan diets. Their dietary choices are motivated either by necessity (e.g., scarcity of resources, allergies or intolerances to animal-derived food products) or by ethical or health concerns (e.g., desire to take better care of the earth's resources and environment, concern about how farm animals are treated, fear of antibiotics and growth stimulants in animal products and of animal-born diseases, and understanding of the health advantages associated with plant-based diets).

"Vegetarian diets are associated with the many health benefits that a higher dietary content of fiber, folic acid, vitamins C and E, potassium, magnesium, many phytochemicals, as well as a lower dietary content of sugar, cholesterol, and hydrogenated or trans fats bring. Vegan diets contain even less saturated fat and cholesterol and even more dietary fiber.

"However, vegetarian and vegan diets are also associated with an increased risk of certain nutritional deficiencies. As a result, vegetarians and vegans are advised to supplement their plant-based diets with nutrients that are not readily available from plant sources but
necessary to meet physiological requirements, such as vitamins B-12 and D, calcium, zinc, iron, and long-chain n-3 (omega-3) fatty acids. They are also advised to ensure adequate protein intake.

"The need for protein and other essential nutrients not readily obtained from plant sources is generally satisfied by vegetarian and vegans by consuming nutrient fortified protein-rich non-animal derived foods, snack bars, drink mixes, and concentrated supplements in tablet or liquid form. Fortified foods and supplements are sold widely, and are also used by many athletes and non-vegetarians/-vegans who are concerned with eating a well-balanced, nutrient-dense diet to enhance their physical and mental performance. The available drink mixes and snack bars are, however, generally only eaten between and in addition to regular meals. No center-plate food item is presently available that can provide the supplemental nutrition sought by vegetarians and vegans.

"Therefore, there exists a need for nutrient-dense center-plate food items that provide vegetarians/vegans and non-vegetarians/-vegans both a regular non-animal protein source and the supplemental nutrients a plant-based diet cannot adequately provide. The present invention provides such nutrient-dense meat structured protein products, as well as cost-effective methods and processes for their production."

As a supplement to the background information on this patent, NewsRx correspondents also obtained the inventors' summary information for this patent: "One aspect of the present invention provides nutrient-dense meat structured protein products that comprise at least 30% by weight of water, at least 5% by weight of non-animal protein material, substantially aligned protein fibers, and essential nutrients such as iron, omega-3 fatty acids, calcium, antioxidants, and vitamin B-12.

"Another aspect of the present invention provides processes for producing the nutrient-dense meat structured protein products. In some embodiments, the processes comprise the steps of combining a non-animal protein material and water with at least one heat stable nutrient to form a dough; shearing and heating the dough so as to denature the proteins in the protein material and to produce protein fibers that are substantially aligned in a fibrous structure; and setting the dough to fix the fibrous structure previously obtained. In other embodiments, the processes comprise the steps of combining a non-animal protein material and water to form a dough; shearing and heating the dough so as to denature the proteins in the protein material and to produce protein fibers that are substantially aligned in a fibrous structure; setting the dough to fix the fibrous structure previously obtained, thereby obtaining a protein fibrous product; and subjecting the protein fibrous product to at least one post-processing step that involves addition of an essential nutrient to the meat structured protein products.

"Yet another aspect of the present invention provides nutrient-dense condiments that comprise essential nutrients, in particular non-heat stable nutrients such as omega-3 fatty acids, antioxidants, and vitamin B-12.

"Yet another aspect of the present invention provides packaged food products that comprise meat structured protein products or nutrient-dense meat structured protein products in combination with condiments or nutrient-dense condiments."

For additional information on this patent, see: Anderson, David; Fuller, Justin; Geistlinger, Timothy. Nutrient-Dense Meat Structured Protein Products. U.S. Patent Number 9526267, filed April 15, 2015, and published online on December 27, 2016. Macau University of Science and Technology

**Patent Issued for Oncogenic ROS1 Kinase Inhibitor (USPTO 9526722)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- According to news reporting originating from Alexandria, Virginia, by NewsRx journalists, a patent by the inventors Yao, Xiao Jun (MO, MO); Leung, Lai Han (MO, MO); Luo, Lian Xiang (MO, MO); Zhou, Yan Ling (MO, MO); Liu, Liang (MO, MO), filed on June 19, 2015, was published online on December 27, 2016.

The assignee for this patent, patent number 9526722, is Macau University of Science and Technology (Macau, CN).

Reporters obtained the following quote from the background information supplied by the inventors: "Receptor tyrosine kinases (RTKs) are vital mediators of extracellular signals, which direct cell growth, survival and motility pathways. Several pathogenesis including chromosomal rearrangements, gene amplification, and point mutations result in abnormal and constitutive RTK activation which is in turn responsible for initiation and progression of many cancers, including non-small cell lung cancer (NSCLC). The first targetable fusion gene of RTK identified in NSCLC is Echinoderm microtubule associated protein like 4 ((EML4)-ALK). Oncogenic c-ros oncogene1 (ROS1) RTK is later reported to be fused with other forms of lung constitutive expressed 5' or 3'-fusion gene partners in NSCLC. Approximately 1.about.2% of NSCLC patients harbor multiple kinds of ROS1 chromosome rearrangement. Recent developments in targeted-based therapies have led to a major paradigm shift in oncology. Small-molecule tyrosine kinase inhibitors are applied to treat cancer patients who have tyrosine kinase gene fusions. Several tyrosine kinase inhibitors have been shown to have promising effect in the clinical practice. For example, Crizotinib, a potent ATP-competitive small molecule inhibitor of ALK, have now been approved by the FDA for treating NSCLC patients that are ALK rearrangement-positive. Crizotinib displays marked anti-tumor activity both in vitro and in vivo as well as in clinical practices. Since the tyrosine kinase domains of ALK and ROS1 are very similar, with 77% identity within the ATP-binding sites, most ALK inhibitors have cross activity against ROS1. In one early clinical trial of crizotinib to treat NSCLC patients harboring ROS1 rearrangements, the objective response rate was 72%, the median duration of response was 17.6 months and median progression-free survival was 19.2 months. Although most patients with ROS1-positive NSCLC exhibit substantial clinical benefit from Crizotinib, the efficacy of Crizotinib is limited by the development of acquired drug resistance. Accordingly, there is a need for new compound targeting ROS1 for cancer treatment."

In addition to obtaining background information on this patent, NewsRx editors also obtained the inventors' summary information for this patent: "The first aspect of the present invention relates to a compound having structure of "##STR00001##"The second aspect of the present invention relates to a composition comprising the compound of Formula I. One embodiment of the second aspect of the present invention relates to use of the composition comprises the compound of Formula I to inhibit activity of oncogene receptor tyrosine kinase (ROS1). The composition inhibits ROS1 kinase activity and suppresses phosphorylation of ROS1, as well as anti-apoptotic and growth signaling downstream to ROS1. "The third aspect of the present invention relates to a method of treating cancer.
comprising administering a composition comprises a compound of Formula I to a subject in need thereof. The subject in need thereof is a subject having an abnormality in ROS1 gene. The abnormality of ROS1 gene may be ROS1 chromosome rearrangement and/or ROS1 gene fusion. The subject in need thereof is ROS1-positive NSCLC individual. In one embodiment of the third aspect of the present invention, the cancer treated is non-small cell lung cancer (NSCLC).

"Those skilled in the art will appreciate that the invention described herein is susceptible to variations and modifications other than those specifically described.

"The invention includes all such variation and modifications. The invention also includes all of the steps and features referred to or indicated in the specification, individually or collectively, and any and all combinations or any two or more of the steps or features.

"Unless otherwise defined, all technical terms used herein have the same meaning as commonly understood to one of ordinary skill in the art to which the invention belongs.

"Other and advantages of the invention will be apparent to those skilled in the art from a review of the ensuing description."

ForSight Vision4, Inc.

Patent Issued for Ophthalmic Implant for Delivering Therapeutic Substances (USPTO 9526654)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- ForSight Vision4, Inc. (Menlo Park, CA) has been issued patent number 9526654, according to news reporting originating out of Alexandria, Virginia, by NewsRx editors.

The patent's inventors are Erickson, Signe (Menlo Park, CA); Campbell, Randolph E. (Menlo Park, CA); Doud, Darren (Menlo Park, CA).

This patent was filed on March 27, 2014 and was published online on December 27, 2016.

From the background information supplied by the inventors, news correspondents obtained the following quote: "Diseases that affect vision can be treated with a variety of therapeutic agents, but the delivery of drugs to the eye continues to be challenging. Injections of therapeutic via the eye can be painful, involve some risk of infection, hemorrhage and retinal detachment. Depending on the frequency, intra-ocular injections can be time-consuming for both patient and physician. Consequently, in at least some instances the drug may be administered less often than the prescribed frequency resulting in sub-optimal treatment benefit. Further, bolus intra-ocular injections may not provide the ideal pharmacokinetics and
pharmacodynamics. A bolus injection of drug into the vitreous humor of a patient can result in a peak drug concentration several times higher than the desired therapeutic amount and then before the patient is able to get the next injection drop to a drug concentration that is far below therapeutic effectiveness."

Supplementing the background information on this patent, NewsRx reporters also obtained the inventors’ summary information for this patent: "In one aspect, disclosed is an implantable therapeutic device to treat a patient. The device includes a hollow refillable housing for implantation within the posterior segment of an eye through a penetration in the sclera of the eye. The housing has a proximal end region. A proximal retention structure protrudes outward from the proximal end region and has an access portion opening. A penetrable barrier is positioned at least in part within the access portion opening and is configured to be repeatedly penetrated. A rigid porous structure is positioned within a region of the housing away from the access portion opening. A reservoir chamber extends along an axis between the penetrable barrier and the porous structure. The reservoir chamber includes a volume sized to deliver therapeutic amounts of a therapeutic agent to the eye for an extended period of time. The access portion opening opens into the reservoir chamber. A cover is coupled to at least an upper surface of the proximal retention structure.

"In some variations, one or more of the following can optionally be included in any feasible combination in the above methods, apparatus, devices, and systems.

"The access portion opening can be over-molded by the cover. The cover can encapsulate and bond the proximal retention structure and an upper surface of the penetrable barrier can be positioned within the access portion opening. The cover can encapsulate and bond to at least an upper surface of the proximal retention structure. The cover can encapsulate and bond to a lower surface of the proximal retention structure. The cover can maintain a seal of the reservoir chamber volume. The cover and the proximal retention structure can have the same shape profile. The cover and the penetrable barrier can be penetrated during filling of the reservoir chamber. The cover and the penetrable barrier can be configured to reseal after penetration of the reservoir chamber. The proximal retention structure can include one or more through-holes. The penetrable barrier can be pre-molded and the cover can be over-molded. The penetrable barrier can be of a soft, high strength material and the cover can be a high durometer material. The cover can be a translucent material. The device can further include an anchor positioned within the access portion opening and in contact with at least a portion of the penetrable barrier. The penetrable barrier can further include a distal region that is flared and positioned within a proximal end region of the reservoir chamber.

"In an interrelated aspect, disclosed is an implantable therapeutic device to treat a patient having a hollow refillable housing for implantation within the posterior segment of an eye through a penetration in the sclera of the eye. The housing has a proximal end region. A proximal retention structure is protruding outward from the proximal end region and includes an access portion opening. A penetrable barrier is positioned at least in part within the access portion opening. The penetrable barrier is configured to be repeatedly penetrated. A rigid porous structure is positioned within a region of the housing away from the access portion opening. A reservoir chamber extends along an axis between the penetrable barrier and the porous structure. The reservoir chamber has a volume sized to deliver therapeutic amounts of a therapeutic agent to the eye for an extended period of time. The access portion opening opens into the reservoir chamber. An anchor is positioned within the access portion opening and in contact with at least a portion of the penetrable barrier.

"In some variations, one or more of the following can optionally be included in any feasible combination in the above methods, apparatus, devices, and systems.
"The penetrable barrier can be pre-molded with soft, high strength material. The anchor can be formed of a high durometer material that resists deformation. The penetrable barrier can be bonded to the anchor creating a single septum structure. The anchor can engage an undercut feature in the proximal end of the housing. The penetrable barrier can apply radial compression to the anchor. The device can further include a cover or a surface of the proximal retention structure. The device can further include a sealant element positioned within a proximal end region of the reservoir chamber and coupled to the penetrable barrier.

"More details of the devices, systems, and methods are set forth in the accompanying drawings and the description below. Other features and advantages will be apparent from the description and drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

"These and other aspects will now be described in detail with reference to the following drawings. Generally speaking, the figures are not to scale in absolute terms or comparatively but are intended to be illustrative. Also, relative placement of features and elements may be modified for the purpose of illustrative clarity.

"FIG. 1 is a cross-sectional, schematic view of a portion of the human eye;

"FIG. 2 is a cross-sectional, schematic view of a portion of the human eye having an implementation of a therapeutic device implanted therein;

"FIG. 3A is an exploded, perspective view of an implementation of a therapeutic device;

"FIGS. 3B-3C are exploded, side views of the therapeutic device of FIG. 3A;

"FIGS. 3D-3E are top and bottom views, respectively, of the therapeutic device of FIG. 3A;

"FIG. 3F is a side, cross-sectional view of the therapeutic device of FIG. 3A;

"FIGS. 4A-4B are perspective and cross-sectional partial views, respectively, of an implementation of a therapeutic device;

"FIG. 5 is a side, cross-sectional partial view of an implementation of a therapeutic device;

"FIG. 6 is a side, cross-sectional partial view of an implementation of a therapeutic device."

THE PHANTOM LABORATORY, INCORPORATED

Patent Issued for Phantom and Method for Image Quality Assessment of a Digital Breast Tomosynthesis System (USPTO 9526471)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- From Alexandria, Virginia, NewsRx journalists report that a patent by the inventors Goodenough, David J. (Myersville, MD); Levy, Joshua R. (Salem, NY), filed on April 25, 2014, was published online on December 27, 2016.

The patent's assignee for patent number 9526471 is THE PHANTOM LABORATORY, INCORPORATED (Greenwich, NY).

News editors obtained the following quote from the background information supplied by the inventors: "The present invention relates generally to the field of image quality assessment of medical imaging systems and, more particularly, to a phantom and method of assessing imaging quality of a digital breast tomosynthesis system.

"Breast cancer remains one of the most common cancers among women despite early detection methods such as breast self-examination, annual mammograms and clinical breast exams. The objective of screening mammography is to identify cancers while they are small and localized. However, some breast cancers still are missed while in their earliest stages, and it is widely agreed that imaging of dense breasts can be improved.

"In conventional two dimensional film or full field digital mammography (FFDM), overlapping dense fibroglandular tissue within the breast can reduce the visibility of malignant abnormalities or simulate the appearance of an abnormality. This can lead to unnecessary patient recalls, biopsies and psychological stress. In addition, mammography is known to be less sensitive in women with dense breasts, who are at higher risk of developing breast cancer.

"Digital breast tomosynthesis (DBT), also referred to as three-dimensional (3D) mammography, is a newly developed form of three-dimensional imaging with the potential to improve the accuracy of mammography by reducing tissue overlap. This overlap, which is sometimes known as anatomical noise, degrades image quality in standard 2D projection imaging and can mask suspicious areas.

"In DBT, the breast is compressed, in the standard fashion, between a compression paddle or plate and a breast support plate overlying an image receptor/detector. With the breast kept stationary, an x-ray tube is moved in an arcuate or isocentric motion and a series of low-dose images, known as projections, are taken at different angular locations of the tube over a limited total angular range known as the scan angle. The projections undergo a reconstruction process using algebraic reconstruction algorithms to produce high resolution images, also known as tomographic sections or slices, in planes parallel to the breast support plate. The number of reconstructed slices will depend upon the thickness of the compressed breast and the desired separation between slices, which might typically be around 1 mm. These sections can be viewed on a work station, either as individual slices or sequentially in a dynamic video mode. By minimizing the superimposition of overlying breast tissue, DBT has the potential to differentiate malignant features more definitively from non-malignant ones.

"Removal of confusing overlying tissue provides clearer imaging, better sensitivity and fewer patient recalls with DBT. Digital breast tomosynthesis also has the potential for lower radiation dosage and less breast compression. Significantly, by detecting breast cancer early, a woman's chances of survival are higher and she may have more treatment options available to her.
"Tomosynthesis differs from computed tomography (CT) in several significant aspects. In DBT, projections are obtained over only a limited range of angles, while in CT, projections are obtained through either 180° or 360° rotations of x-ray tubes and detectors.

"In conventional computed tomography (CT), a plane of interest is established by moving the detector and the x-ray tube in opposite directions. This establishes a plane of interest (or a plane of focus). Features within the plane of focus appear relatively sharp. A major disadvantage of this approach is that there is only a single plane of focus for each exposure and geometric configuration. Another disadvantage of CT imaging of the breast is the higher radiation dose involved in conventional system designs.

"In contrast, in tomosynthesis, an arbitrary number of planes may be retrospectively reconstructed from a single sequence of projection images. Typically, a series of projection images is obtained while the x-ray tube moves in a limited arcuate or linear motion. (However, the motion of the x-ray tube could be more complex and the imaging detector could be stationary or moving.) After the acquisition sequence is complete, the projection images are combined by shifting and adding these together to bring a specific plane into focus. Different planes can be brought into focus by varying the amount of shifting. Advantages of tomosynthesis over conventional projection imaging include: depth localization, improved conspicuity owing to the removal of the clutter caused by overlying tissue structures, and improved contrast of local structure by limiting the dynamic range to a single plane.

"The differences between tomosynthesis and CT impose different requirements on phantoms and methods of assessing image quality in the two different imaging modalities. As opposed to relatively well defined slices with finite extension in CT, tomosynthesis slices are less well defined with some degree of extension from the center of the slice of interest to the boundaries of the object being considered. Due to their disparate methods of reconstruction, artifacts and image problems are very different in tomosynthesis as compared to CT, and new and different approaches to the measurement of image quality in tomosynthesis are needed.

"In a recent study, entitled 'Evaluation of Various Mammography Phantoms for Image Quality Assessment in Digital Breast Tomosynthesis' by Claudia Brunner et al, four different existing mammography phantoms were investigated for their appropriateness for image quality evaluation in Digital Breast Tomosynthesis. This study concluded that, 'Although each phantom under study has its advantages, none of them allows a thorough quality evaluation of reconstructed tomosynthesis images'. It can also be noted from this study, that modulation transfer function (MTF) data is only available from transforming edge response function in one direction at a time, and no point source for 2D information and 2D MTF transform is available. Cited deficiencies in all phantoms studied include slice sensitivity profile.

"In a 'Protocol for the Quality Control of the Physical and Technical aspects of Digital Breast Tomosynthesis Systems', draft version 0.10, published in February 2013, by the European Reference Organisation for Quality Assured Breast Screening and Diagnostic Services (EUREF), a phantom for z-resolution in DBT is disclosed that comprises a planar array of 25 spaced apart aluminum spheres. In use, this phantom, must be repositioned and exposed at multiple different heights in a time consuming and repetitive procedure.

"The present invention provides a phantom and method of image quality assessment specifically tailored and optimized for digital breast tomosynthesis systems."

As a supplement to the background information on this patent, NewsRx correspondents also obtained the inventors' summary information for this patent: "According to the present invention, a phantom for calibrating a tomosynthesis imaging system includes at least one set of beads arranged as a first ramp and a second ramp in respective proximate
parallel vertical planes in a reverse staircase pattern along a vertical direction, with a final bead of the first ramp and an initial bead of the second ramp being located at substantially the same intermediate height within the phantom. The reverse staircase pattern may include a first ramp of spaced apart beads disposed in a first vertical plane and extending from a lower end of the first ramp along a first inclination up to a final end of the first ramp at an intermediate height of the phantom, and a second ramp of spaced apart beads disposed in a second vertical plane and extending from near the final end of the first ramp at the intermediate height up and back along a second inclination. The second vertical plane is located parallel to, and spaced from, the first vertical plane.

"The second vertical plane may be located adjacent the first vertical plane, and the beads of the second plurality do not vertically overlap the beads of the first plurality.

"The beads of the first plurality and/or of the second plurality may be spherical and may be identical in size. Each bead preferably has a size smaller than or comparable to resolution size of the imaging system or a small size, the impact of which may be calculated and used to correct (deconvolve) the effect of the bead size on the measured slice width of the tomosynthesis system. Each bead may comprise a solid sphere of metal or other material having a signal strength within a dynamic range of the imaging system, and may have a size and composition to minimize artifact spread function in other z-axis image planes. Center-to-center spacing of adjacent beads in the first plurality and/or the second plurality should be sufficient to avoid streaking of the beads into one another in an imaging plane.

"The first ramp of beads and the second ramp of beads of the phantom may be embedded in a uniform material that mimics x-ray attenuation of breast tissue. Preferably, full horizontal extent of the first ramp in the first vertical plane is substantially equal to full horizontal extent of the second ramp in the second vertical plane.

"The phantom may advantageously include at least one additional test object located in a position so as not to vertically overlap with the beads. The additional test object may include at least one of: spheres of different diameters, a square, for example, of thin Aluminum, fiducial markers, and at least one graded step incrementation ruler to measure missing tissue at a simulated chest wall.

"The first ramp and the second ramp of beads and the at least one additional test object preferably comprise a single test module of the phantom. The phantom may also include a blank non-structured module and/or a structured module that simulates a breast pattern. The additional module(s) may serve as a spacer for the test module.

"In another aspect of the present invention, the phantom may include at least two sets of beads, each being arranged as a first ramp and a second ramp in respective proximate parallel vertical planes in a reverse staircase pattern along the vertical direction, the at least two sets being horizontally spaced apart on opposite sides of the phantom, with the first ramp of the first set ascending in a first direction and the first ramp of the second set ascending in an opposite direction.

"The present invention also contemplates a method for image quality assessment of a tomosynthesis imaging system. The method may include providing a phantom having at least one set of beads arranged as a first ramp and a second ramp in respective proximate parallel planes in a reverse staircase pattern along a vertical direction with a final bead of the first ramp and an initial bead of the second ramp being located at substantially the same intermediate height within the phantom, scanning the phantom with the tomosynthesis imaging system; and, with results of scanning of the at least one set of beads, determining slice sensitivity profile along the vertical direction and at least one of: point spread function of at least one bead in a horizontal plane, or line spread function of at least one bead in the horizontal plane, or a two-
dimensional modulation transfer function as a function of spatial frequency. This determining may, advantageously, be based on a single scanning sequence of the phantom, and is preferably automated.

"According to another aspect of the invention, the slice sensitivity profile may be determined by plotting peak intensity of each bead as a function of bead vertical position, or integrating total bead intensity at each bead vertical position, or deriving a metric of bead intensity values as a function of each bead vertical position.

"According to a further aspect of the invention, the phantom may further includes a square, and the method may further include determining at least one of line spread function or modulation transfer function from scanning the square.

"The present invention further contemplates a method for image quality assessment of a digital breast tomosynthesis imaging system employing a phantom having a first ramp of spaced apart beads disposed in a first vertical plane and extending from a lower end of the first ramp along a first inclination up to a final end of the first ramp at an intermediate height of the phantom, a second ramp of spaced apart beads disposed in a second vertical plane, parallel and proximate the first vertical plane, and extending from near the final end of the first ramp at the intermediate height up and back along a second inclination, spheres of different diameters, a square, fiducial markers, and at least one graded step incrementation rule, all embedded, in a uniform material, in a single test module. The method may include scanning this phantom with the tomosynthesis imaging system; and, with results of said scanning, determining by automated analysis: slice sensitivity profile along a vertical direction from the beads, point spread function and corresponding modulation transfer function of at least one bead in a horizontal plane, contrast detail from the spheres of different diameters, low contrast contrast-to-noise ratio from the square, geometric distortion from the fiducial markers, and missed tissue at a simulated chest wall using the at least one graded step incrementation ruler."

NEUROPORE THERAPIES, INC.

Patent Issued for Phenyl-Urea and Phenyl-Carbamate Derivatives as Inhibitors of Protein Aggregation (USPTO 9527852)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A patent by the inventor Wrasidlo, Wolfgang (San Diego, CA), filed on March 15, 2013, was published online on December 27, 2016, according to news reporting originating from Alexandria, Virginia, by NewsRx correspondents.

Patent number 9527852 is assigned to NEUROPORE THERAPIES, INC. (San
The following quote was obtained by the news editors from the background information supplied by the inventors: "Neurodegenerative disorders of the aging population such as Alzheimer's disease (AD), Parkinson's disease (PD), and fronto-temporal dementia (FTD), affect over 20 million people in the United States and European Union alone and rank among the top causes of death for the elderly. A common feature among these neurological disorders is the chronic accumulation of proteins into neurotoxic aggregates. Each disease is characterized by the specific neuronal populations that are affected, the particular protein aggregates that are involved, and the clinical features that result from the neuronal degeneration.

"Studies suggest that the initial stages of protein aggregation involve mutation or post-translational modification (e.g., nitrosilation, oxidation) of the target protein, which then adopts an abnormal conformation that facilitates interactions with similarly misfolded proteins. The abnormal proteins then aggregate to form dimers, trimers, and higher-order multimers, also termed 'soluble oligomers,' which may disrupt synaptic function. Additionally, the aggregates may then anchor in the cell membrane and form globular oligomers (which in turn can form pores in the membrane) and/or protofibrils or fibrils. These larger, insoluble fibrils may function as reservoirs of the bioactive oligomers.

"The particular proteins implicated in these neurodegenerative diseases vary in identity and source. For example, in AD, the neurotoxic aggregates are composed of the secreted protein amyloid-beta (A(.beta.). In idiopathic Parkinson's disease (IPD), dementia with Lewy bodies (LBD), PD dementia (PDD), and multiple system atrophy (MSA), the neurotoxic aggregates are composed of .alpha.-synuclein (SYN), which is a synaptic protein that is intracellular under normal conditions. In FTD and amyotrophic lateral sclerosis (ALS), neurotoxic aggregates originate from other intracellular proteins such as tau, TDP-43, or SOD1. For certain diseases, such as AD, SYN aggregates with the primary protein. Thus, compounds that interfere with SYN aggregation may impact neurodegenerative pathologies of various etiologies.

"Two mechanisms are implicated in these neurodegenerative processes. In the first, the misfolded and/or aggregated proteins anchor to the various cell membrane structures. Binding of the misfolded or aggregated molecules to the plasma membrane or the membranes of organelles (e.g., mitochondria or lysosomes) may interfere with protein transcription, autophagy, mitochondrial function, and pore formation. By way of example, neurotoxic SYN aggregates and interacts with lipids in cell membranes, by a specific portion of the c-terminal region of the synuclein protein. Compounds that bind to this region can inhibit protein-protein or protein-lipid interactions and can therefore be used to block neurotoxic SYN oligomerization and membrane interaction. In the second process, aggregated protein is released from the anchored subunit and propagates to adjacent cells. This cell-to-cell propagation of toxic protein aggregates may then underlie the anatomic progression of neurodegeneration and worsening of symptoms. Small molecule drugs that interact with the target proteins may limit release and/or propagation, and therefore reduce the neurotoxic effects of aggregated proteins. Such compounds may therefore provide new therapies for AD, PD, LBD, MSA, and related neurodegenerative conditions.

"There remains a need for inhibitors of protein aggregation with desirable pharmaceutical properties. Certain phenyl-urea and carbamate derivatives have been found in the context of this invention to have protein aggregation modulating activity."

In addition to the background information obtained for this patent, NewsRx journalists also obtained the inventor's summary information for this patent: "In one aspect, the invention relates to a chemical entity of the following Formula (I):
"##STR00001## wherein Het is a bicyclic heteroaryl in which at least one ring atom is a N, and said heteroaryl is unsubstituted or is substituted with one or more R.sup.a substituents; wherein each R.sup.a is independently hydroxyl, halo, amino, cyano, nitro, C.sub.1-4alkyl, haloalkyl, C.sub.1-4alkoxy, or halo-C.sub.1-4alkoxy; X is --CH.sub.2--; R.sup.z--, wherein R.sup.z is absent, --CH.sub.2--, --O--, --S--, or --NH--; one of W and Y is NH and the other is O or NH; Z is O or S; R.sup.1 is --NR.sup.bR.sup.c; guanidino; a monocyclic heteroaryl in which at least one ring atom is a N, and said heteroaryl is unsubstituted or is substituted with one or more R.sup.d substituents; or a monocyclic heterocycloalkyl, in which at least one ring atom is a N, and said heterocycloalkyl is unsubstituted or is substituted with one or more R.sup.e substituents; wherein R.sup.b and R.sup.c are each independently H or C.sub.1-4alkyl; each R.sup.d is independently hydroxyl, halo, amino, cyano, nitro, C.sub.1-4alkyl, haloalkyl, C.sub.1-4alkoxy, or halo-C.sub.1-4alkoxy; and each R.sup.e is independently hydroxyl, halo, amino, cyano, nitro, C.sub.1-4alkyl, haloalkyl, C.sub.1-4alkoxy, --C(O)C.sub.1-4alkyl, or --CO.sub.2C.sub.1-4alkyl; n is 0, 1, 2, 3, or 4; R.sup.2 is absent or is hydroxyl, methoxy, or trifluoromethoxy; and R.sup.3 is C.sub.1-6alkyl, C.sub.1-6alkoxy or C.sub.3-8cycloalkoxy, wherein said cycloalkoxy is unsubstituted or substituted with one or more substituents independently selected from the group consisting of hydroxyl, halo, amino, cyano, nitro, C.sub.1-4alkyl, haloalkyl, C.sub.1-4alkoxy, and halo-C.sub.1-4alkoxy; or a pharmaceutically acceptable salt thereof.

"In certain embodiments, the compound of Formula (I) is a compound selected from those species described or exemplified in the detailed description below.

"In another aspect, the invention relates to a pharmaceutical composition comprising at least one compound of Formula (I) or a pharmaceutically acceptable salt thereof. Pharmaceutical compositions according to the invention may further comprise a pharmaceutically acceptable excipient. The invention is also a compound of Formula I or a pharmaceutically acceptable salt thereof for use as a medicament.

"In another aspect, the invention is directed to a method of treating a neurodegenerative disease or condition associated with protein aggregation comprising administering to a subject in need of such treatment an effective amount of at least one compound of Formula (I) or a pharmaceutically acceptable salt thereof.

"In another aspect, the invention is directed to a method of treating a disease or medical condition associated with protein aggregation, comprising administering to a subject in need of such treatment an effective amount of at least one compound of Formula (I) or a pharmaceutically acceptable salt thereof. The invention is also directed at use of a compound of Formula I in the preparation of a medicament for the treatment of such diseases and medical conditions, and the use of such compounds and salts for treatment of such diseases and medical conditions.

"In yet another aspect, the invention relates to a method of interfering with the accumulation of protein or peptide aggregation in a cell, or preventing, slowing, reversing, or inhibiting protein or peptide aggregation in a cell, comprising contacting the cell with an effective amount of at least one compound of Formula (I) or a salt thereof, and/or with at least one pharmaceutical composition of the invention, wherein the contacting is in vitro, ex vivo, or in vivo.

"Additional embodiments, features, and advantages of the invention will be apparent from the following detailed description and through practice of the invention.

"For the sake of brevity, the disclosures of the publications cited in this specification, including patents, are herein incorporated by reference."

Duchesnay Inc.

Patent Issued for Plurimodal Release Formulation of Doxylamine and Pyridoxine And/Or Metabolites Or Salts (USPTO 9526703)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Duchesnay Inc. (Blainville, CA) has been issued patent number 9526703, according to news reporting originating out of Alexandria, Virginia, by NewsRx editors.

The patent's inventors are Vrandeck, Manon (St-Lazare, CA); St-Onge, Jean-Luc (Mirabel, CA); Gallo, Michele (Blainville, CA); Gervais, Eric (Blainville, CA).

This patent was filed on August 28, 2015 and was published online on December 27, 2016.

From the background information supplied by the inventors, news correspondents obtained the following quote: "Nausea and vomiting of pregnancy (NVP), also referred to as 'morning sickness,' is very common. It afflicts 50% to 80% of pregnant women with varying degrees of severity.

"Commonly occurring within the first 4 to 16 weeks of pregnancy, approximately 20% of women will continue to experience NVP for a longer period of time. Some women may suffer from NVP until the end of the pregnancy. Nausea and vomiting can have serious adverse effects. If severe enough, NVP can cause dehydration, with associated salt and vitamin imbalances. These and other effects can be harmful to the health of the woman and the well-being of her baby. In its most severe form, NVP may manifest itself as hyperemesis gravidarum, a potentially life threatening condition affecting 0.5% to 2% of pregnancies, which is characterized by protracted vomiting, retching, severe dehydration, and weight loss requiring hospitalization.

"The delayed release combination of doxylamine succinate/pyridoxine HCl (10 mg each), marketed in Canada under the trade-name Diclectin.RTM. and in the United States under the trade-name Diclegis.RTM., is the only medication approved in Canada and U.S. for the treatment of NVP. Its safety and effectiveness for the treatment of NVP is recognized by the medical community, and its safety throughout pregnancy has been long established.

"Nevertheless, there is a need for the development of novel pharmaceutical dosage systems and forms, for example those having an improved pharmacokinetics profile and/or stability, for the prevention and treatment of nausea and vomiting, such as in NVP.

"The present description refers to a number of documents, the content of which is
herein incorporated by reference in their entirety."

Supplementing the background information on this patent, NewsRx reporters also obtained the inventors' summary information for this patent: "The present invention relates to the following items 1 to 49:

"1. A solid oral dosage form comprising: a core comprising about 5 mg to about 40 mg of doxylamine or a salt thereof and about 5 mg to about 40 mg of pyridoxine or a salt thereof; an enteric coating surrounding said core; a first active ingredient-containing coating surrounding said enteric coating and comprising (i) about 5 mg to about 40 mg of doxylamine or a salt thereof, or (ii) about 5 mg to about 40 mg of pyridoxine or a salt thereof; and a second active ingredient-containing coating surrounding said intermediate coating and comprising (i) about 5 mg to about 40 mg of doxylamine or a salt thereof, or (ii) about 5 mg to about 40 mg of pyridoxine or a salt thereof; wherein if said first active ingredient-containing coating comprises said doxylamine or salt thereof, said second active ingredient-containing coating comprises said pyridoxine or salt thereof, and if said first active ingredient-containing coating comprises said pyridoxine or salt thereof, said second active ingredient-containing coating comprises said doxylamine or salt thereof.

"2. The solid oral dosage form of item 1, wherein said core comprises about 10 mg of said doxylamine or salt thereof.

"3. The solid oral dosage form of item 1 or 2, wherein said core comprises doxylamine succinate.

"4. The solid oral dosage form of any one of items 1 to 3, wherein said core comprises about 10 mg of said pyridoxine or salt thereof.

"5. The solid oral dosage form of any one of items 1 to 4, wherein said core comprises pyridoxine hydrochloride.

"6. The solid oral dosage form of any one of items 1 to 5, wherein said first or second active ingredient-containing coating comprises about 10 mg of said doxylamine or salt thereof.

"7. The solid oral dosage form of any one of items 1 to 6, wherein said first or second active ingredient-containing coating comprises doxylamine succinate.

"8. The solid oral dosage form of any one of items 1 to 7, wherein said first or second active ingredient-containing coating comprises about 10 mg of said pyridoxine or salt thereof.

"9. The solid oral dosage form of any one of items 1 to 8, wherein said first or second active ingredient-containing coating comprises pyridoxine hydrochloride.

"10. The solid oral dosage form of any one of items 1 to 9, wherein said first and/or second active ingredient-containing coating comprises a film coating system

"11. The solid oral dosage form of item 10, wherein said film coating system comprises a polymer and a plasticizer.

"12. The solid oral dosage form of any one of items 1 to 11, wherein said core is present in an amount of about 50% to about 70% (w/w) of said solid oral dosage form.

"13. The solid oral dosage form of item 12, wherein said core is present in an amount of about 55% to about 65% (w/w) of said solid oral dosage form.

"14. The solid oral dosage form of any one of items 1 to 13, wherein said enteric coating is present in an amount of about 2% to about 15% (w/w) of said solid oral dosage form.

"15. The solid oral dosage form of item 14, wherein said enteric coating is present in an amount of about 4% to about 12% (w/w) of said solid oral dosage form.
"16. The solid oral dosage form of any one of items 1 to 15, wherein said enteric coating comprises an acrylic polymer or co-polymer.

"17. The solid oral dosage form of item 16, wherein said acrylic polymer or co-polymer is a copolymer based on methacrylic acid and ethyl acrylate.

"18. The solid oral dosage form of any one of items 1 to 17, wherein said first active ingredient-containing coating is present in an amount of about 4% to about 12% (w/w) in said solid oral dosage form.

"19. The solid oral dosage form of item 18, wherein said first active ingredient-containing coating is present in an amount of about 6% to about 10% (w/w) in said solid oral dosage form.

"20. The solid oral dosage form of any one of items 1 to 19, further comprising a first intermediate coating surrounding said first active ingredient-containing coating.

"21. The solid oral dosage form of item 20, wherein said first intermediate coating is present in an amount of about 1% to about 4% (w/w) in said solid oral dosage form.

"22. The solid oral dosage form of item 21, wherein said first intermediate coating is present in an amount of about 2% to about 3% (w/w) in said solid oral dosage form.

"23. The solid oral dosage form of any one of items 20 to 22, wherein said first intermediate coating comprises a film coating system.

"24. The solid oral dosage form of item 23, wherein said film coating system comprises a polymer and a plasticizer.

"25. The solid oral dosage form of any one of items 1 to 24, wherein said second active ingredient-containing coating is present in an amount of about 5% to about 15% (w/w) of said solid oral dosage form.

"26. The solid oral dosage form of item 25, wherein said second active ingredient-containing coating is present in an amount of about 8% to about 12% (w/w) of said solid oral dosage form.

"27. The solid oral dosage form of any one of items 1 to 26, further comprising a second intermediate coating between said core and said enteric coating.

"28. The solid oral dosage form of item 27, wherein said second intermediate coating is present in an amount of about 1% to about 8% (w/w) of said solid oral dosage form.

"29. The solid oral dosage form of item 28, wherein said second intermediate coating is present in an amount of about 2% to about 6% (w/w) of said solid oral dosage form.

"30. The solid oral dosage form of any one of items 24 to 26, wherein said second intermediate coating comprises a film coating system comprising a polymer and a plasticizer.

"31. The solid oral dosage form of any one of items 27 to 30, further comprising a seal coating surrounding said second active ingredient-containing coating.

"32. The solid oral dosage form of item 31, wherein said seal coating is present in an amount of about 2% to about 10% (w/w) of said solid oral dosage form.

"33. The solid oral dosage form of item 32, wherein said seal coating is present in an amount of about 4% to about 8% (w/w) of said solid oral dosage form.

"34. The solid oral dosage form of any one of items 31 to 33, wherein said seal coating comprises a film coating system.

"35. The solid oral dosage form of item 34, wherein said film coating system comprises a polymer and a plasticizer.

"36. The solid oral dosage form of any one of items 31 to 35, further comprising a solid oral dosage form-coating agent surrounding said seal coating.
"37. The solid oral dosage form of item 36, wherein said solid oral dosage form-coating agent is present in an amount of about 0.005% to about 0.5% (w/w) of said solid oral dosage form.

"38. The solid oral dosage form of item 36 or 37, wherein said solid oral dosage form-coating agent comprises wax.

"39. The solid oral dosage form of any one of items 1 to 38, wherein said core further comprises one or more pharmaceutically acceptable excipients.

"40. The solid oral dosage form of item 39, wherein said core comprises microcrystalline cellulose, colloidal silicon dioxide, magnesium trisilicate, croscarmellose sodium and magnesium stearate.

"41. The solid oral dosage form of item 40, wherein said core comprises about 60% to about 65% (w/w) of microcrystalline cellulose, about 0.5 to about 1% (w/w) of colloidal silicon dioxide, about 16% to about 20% (w/w) of magnesium trisilicate, about 2% to about 3% (w/w) of croscarmellose sodium, and about 2% to about 3% (w/w) of magnesium stearate.

"42. The solid oral dosage form of any one of items 1 to 41, wherein said solid oral dosage form is a tablet.

"43. The solid oral dosage form of any one of items 1 to 42, for use in alleviating the symptoms of nausea and vomiting of human pregnancy.

"44. The solid oral dosage form of any one of items 1 to 42, for use in the manufacture of a medicament for alleviating the symptoms of nausea and vomiting of human pregnancy.

"45. Use of the solid oral dosage form of any one of items 1 to 42, for alleviating the symptoms of nausea and vomiting of human pregnancy.

"46. Use of the solid oral dosage form of any one of items 1 to 42, for the manufacture of a medicament for alleviating the symptoms of nausea and vomiting of human pregnancy.

"47. A method for alleviating the symptoms of nausea and vomiting of human pregnancy, said method comprising administering the solid oral dosage form of any one of items 1 to 42 to a pregnant human female in need thereof.

"48. A package comprising the solid oral dosage form of any one of items 1 to 42.

"49. The package of item 48, further comprising instructions for use of said solid oral dosage form for alleviating the symptoms of nausea and vomiting of human pregnancy.

"The present invention also relates to the following items 1a to 30a:

"1a. A solid oral dosage form comprising: (a) a core comprising from about 5 mg to about 40 mg of doxylamine and/or a pharmaceutically acceptable salt thereof and from about 5 mg to about 40 mg of pyridoxine and/or a pharmaceutically acceptable salt thereof; (b) an enteric coating surrounding said core; (c) a first active ingredient-containing coating surrounding said enteric coating and comprising (i) from about 5 mg to about 40 mg of doxylamine and/or a pharmaceutically acceptable salt thereof, or (ii) from about 5 mg to about 40 mg of pyridoxine and/or a pharmaceutically acceptable salt thereof; and (d) a second active ingredient-containing coating surrounding said first active ingredient-containing coating and comprising (i) from about 5 mg to about 40 mg of doxylamine and/or a pharmaceutically acceptable salt thereof, or (ii) from about 5 mg to about 40 mg of pyridoxine and/or a pharmaceutically acceptable salt thereof; wherein if said first active ingredient-containing coating comprises said doxylamine and/or pharmaceutically acceptable salt thereof, said second active ingredient-containing coating comprises said pyridoxine and/or pharmaceutically acceptable salt thereof, and if said first active ingredient-containing coating comprises said pyridoxine and/or pharmaceutically acceptable salt thereof.
acceptable salt thereof, said second active ingredient-containing coating comprises said
doxylamine and/or pharmaceutically acceptable salt thereof.

"2a. The solid oral dosage form of item 1a, wherein said core comprises about 10
mg of said doxylamine or pharmaceutically acceptable salt thereof.

"3a. The solid oral dosage form of item 1a, wherein said core comprises doxylamine
succinate.

"4a. The solid oral dosage form of item 1a, wherein said core comprises about 10
mg of said pyridoxine or pharmaceutically acceptable salt thereof.

"5a. The solid oral dosage form of item 1a, wherein said core comprises pyridoxine
hydrochloride.

"6a. The solid oral dosage form of item 1a, wherein said first or second active
ingredient-containing coating comprises about 10 mg of said doxylamine or pharmaceutically
acceptable salt thereof.

"7a. The solid oral dosage form of item 1a, wherein said first or second active
ingredient-containing coating comprises doxylamine succinate.

"8a. The solid oral dosage form of item 1a, wherein said first or second active
ingredient-containing coating comprises about 10 mg of said pyridoxine or pharmaceutically
acceptable salt thereof.

"9a. The solid oral dosage form of item 1a, wherein said first or second active
ingredient-containing coating comprises pyridoxine hydrochloride.

"10a. The solid oral dosage form of item 1a, wherein said first and/or second active
ingredient-containing coating comprises a film coating system.

"11a. The solid oral dosage form of item 1a, wherein said core is present in an
amount of about 50% to about 70% (w/w) of said solid oral dosage form.

"12a. The solid oral dosage form of item 1a, wherein said enteric coating is present
in an amount of about 2% to about 15% (w/w) of said solid oral dosage form.

"13a. The solid oral dosage form of item 1a, wherein said enteric coating comprises
an acrylic polymer or co-polymer.

"14a. The solid oral dosage form of item 13a, wherein said acrylic polymer or co-
polymer is a copolymer based on methacrylic acid and ethyl acrylate.

"15a. The solid oral dosage form of item 1a, wherein said first active ingredient-
containing coating is present in an amount of about 4% to about 12% (w/w) in said solid oral
dosage form.

"16a. The solid oral dosage form of item 1a, further comprising a first intermediate
coating surrounding said first active ingredient-containing coating.

"17a. The solid oral dosage form of item 16a, wherein said first intermediate coating
is present in an amount of about 1% to about 4% (w/w) in said solid oral dosage form.

"18a. The solid oral dosage form of item 16a, wherein said first intermediate coating
comprises a film coating system.

"19a. The solid oral dosage form of item 1a, wherein said second active ingredient-
containing coating is present in an amount of about 5% to about 15% (w/w) of said solid oral
dosage form.

"20a. The solid oral dosage form of item 1a, further comprising a second
intermediate coating between said core and said enteric coating.

"21a. The solid oral dosage form of item 1a, further comprising a third intermediate
coating between said enteric coating and said first active ingredient-containing coating.
"22a. The solid oral dosage form of item 1a, further comprising a seal coating surrounding said second active ingredient-containing coating.

"23a. The solid oral dosage form of item 22a, wherein said seal coating is present in an amount of about 2% to about 10% (w/w) of said solid oral dosage form.

"24a. The solid oral dosage form of item 22a, wherein said seal coating comprises a film coating system.

"25a. The solid oral dosage form of item 22a, further comprising a solid oral dosage form-coating agent surrounding said seal coating.

"26a. The solid oral dosage form of item 25a, wherein said solid oral dosage form-coating agent is present in an amount of about 0.005% to about 0.5% (w/w) of said solid oral dosage form.

"27a. The solid oral dosage form of item 25a, wherein said solid oral dosage form-coating agent comprises wax.

"28a. The solid oral dosage form of item 1a, wherein said solid oral dosage form is a tablet.

"29a. A solid oral dosage form comprising: (a) a core comprising about 10 mg of doxylamine succinate and about 10 mg of pyridoxine hydrochloride; (b) an enteric coating surrounding said core; (c) a first active ingredient-containing coating surrounding said enteric coating and comprising about 10 mg of pyridoxine hydrochloride; (d) a second active ingredient-containing coating surrounding said first active ingredient-containing coating and comprising about 10 mg of doxylamine succinate; (e) a seal coating surrounding said second active ingredient-containing coating; (f) a solid oral dosage form-coating agent surrounding said seal coating; (g) a first intermediate coating between said first active ingredient-containing coating and said second active ingredient-containing coating; (h) a second intermediate coating between said core and said enteric coating; and (i) a third intermediate coating between said enteric coating and said first active ingredient-containing coating.

"30a. A method for alleviating the symptoms of nausea and vomiting of human pregnancy, said method comprising administering the solid oral dosage form of item 1a to a pregnant human female in need thereof.

"Other objects, advantages and features of the present invention will become more apparent upon reading of the following non-restrictive description of specific embodiments thereof, given by way of example only with reference to the accompanying drawings."

Patent Issued for Polymutant Tau Protein Variants and Their Use for Recapitulating Human Tauopathies (USPTO 9527894)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- Universitaet Leipzig (Leipzig, DE) has been issued patent number 9527894, according to news reporting originating out of Alexandria, Virginia, by NewsRx editors.

The patent's inventors are Robitzki, Andrea (Viernheim, DE); Jahnke, Heinz-Georg (Leipzig, DE); Krinke, Dana (Leipzig, DE); Striggow, Frank (Gerwisch, DE); Mack, Till (Magdeburg, DE).

This patent was filed on April 28, 2011 and was published online on December 27, 2016.

From the background information supplied by the inventors, news correspondents obtained the following quote: "Since NFT are the most striking pathological feature in tauopathies, much attention has focused on understanding how the deposition of NFT may cause neurodegeneration, in essence using animal models recapitulating NFT pathology to investigate the mechanism of disease. It has long been postulated that the aggregation of tau into filaments and NFT results in a toxic gain of function. This view has been substantially challenged by observations that neuronal loss and memory impairment can experimentally be cured despite ongoing NFT formation (Santacruz et al. 2005). In some animal models, the tau-mediated loss of neurons does not even require NFT development. Thus, it is assumed that non-filamentous but already aggregated, globular tau intermediates on route to assemble into larger helical filaments may represent the neurotoxic tau species.

"Elevated levels of free tau, not bound to microtubules, presumably increases its likelihood to become misfolded, as well as undergo modifications or conformational changes that promote the formation of aggregated small globular oligomers that eventually will assemble into insoluble filaments. Covalent modifications stabilizing conformational changes most likely include phosphorylation since tau protein isolated from AD brain was found to be abnormally high phosphorylated at multiple critical sites (`hyperphosphorylated tau`) and it was demonstrated that pseudo-hyperphosphorylation (i.e. pseudo-phosphorylated at multiple sites along the protein) can facilitate abnormal conformation of tau protein (Jeganathan et al. 2008). In this context tau hyperphosphorylation was identified as diagnostic target (WO9311231A1) and different tau related Kinases identified as therapeutic target (WO2007088400A1).

"Given that tau is normally a highly soluble protein that does not readily aggregate, this matter has been difficult to assess in experimental models because of the resistance of tau to aggregate within an ideal time-frame for culture studies or within an animal's relatively short lifespan. Because high concentrations of tau are required to promote tau aggregation in experimental models, it is believed that the enhanced ability of tau to form small globular aggregates in the cytoplasm of neurons and glia in human tauopathies may be due to pathological conditions that locally increase the pool of tau available for aggregation. Yet it is unlikely that the amount of tau in various tauopathies is as high as in cell culture and animal models that artificially force massive tau overexpression and, therefore, much caution is needed extrapolating results from such model systems to the human condition.

"Further complicating matters is evidence that mouse tau appears to prevent tau aggregation in transgenic mice overexpressing wild-type human tau (htau). Nonetheless, transgenic mice that overexpress high levels of htau isoforms containing aggregation-promoting
mutations (e.g. P301L tau) can develop tau pathology even in the presence of endogenous mouse tau. The P301L and P301S mutations are among the first described FTD mutations and show a very early mean onset for FTD in man. Tau transgenic mouse models with expression of these mutants display onset of first signs of tau pathology starting at 2.5 to 5 months (Schindowski et al. 2006). WO 01/53340 A2 discloses mouse models expressing wildtype or tau with one mutation like the named P301L mutation for generating a neurodegenerative disease model as well as tool for drug development. Furthermore a transgenic mouse model with tau cDNA bearing three FTD mutations the tau pathology has been described (Lim et al., 2001).

"To accelerate tau aggregation in vitro, polyanionic cofactors or small molecule ligands are often used to facilitate tau aggregation. For example, in a cell culture model overexpressing full length tau, Congo red treatment stimulates the formation of filamentous tau aggregates and decreases cell viability (Bandyopadhyay et al. 2007). These and other results suggest that also in cell culture models tau aggregation causes cell death or, at least, accelerates its onset. However, no cell culture model has been described so far that does not force aggregation of tau by either artificial high concentrations of tau or addition of, at higher doses toxic, compounds in order to facilitate or precipitate aggregation (Ko et al. 2004, Tsukane et al. 2007, Nie et al. 2007). In view of modelling tauopathy disease mechanisms for drug development purposes, both strategies bear a high risk of producing artificial results since the mechanism of degeneration may significantly differ from tau pathology in the AD brain."

Supplementing the background information on this patent, NewsRx reporters also obtained the inventors’ summary information for this patent: "It has been found that cells expressing tau with multiple mutations show signs of neurodegeneration within 24 hours of cell culture. Cells expressing tau proteins with 4 FTDP-17 mutations showed lowered impedance (Example 2/FIG. 5). This was shown for two different tau proteins having different 4 times mutations. The effect was even more pronounced for a tau protein having five different FTDP-17 mutations.

"In a first aspect, the present invention relates to a tau protein comprising at least four different mutations associated with the condition frontotemporal dementia and parkinsonism linked to chromosome 17 (FTDP-17).

"A second aspect of the invention is a nucleic acid encoding the tau protein of the present invention.

"A third aspect of the invention is a plasmid or vector comprising the nucleic acid of the present invention.

"A fourth aspect of the invention is a cell comprising the nucleic acid or the vector or plasmid of the present invention.

"A fifth aspect of the invention is a cell expressing a mutated tau protein, wherein said cell exhibits a decrease in impedance after 24 hours of cell culture.

"A sixth aspect of the present invention is a method for identifying an agent for treating or preventing neurodegenerative disease, comprising (a) contacting a test compound with the cell of the present invention; and (b) determining whether the test substance modulates at least one marker indicative of the neurodegeneration.

"A seventh aspect of the invention is the use of the tau protein of the present invention, of the nucleic acid of the present invention, of the vector or plasmid of the present invention, or of the cell of the present invention for screening an agent or agents capable of modulating one or more markers of neurodegeneration.

"An eighth aspect of the invention is the use of the tau protein of the present invention, of the nucleic acid of the present invention, of the vector or plasmid of the present
invention, or of the cell of the present invention for the development of medicaments for the
treatment or prevention of neurodegenerative diseases.

"A ninth aspect of the invention is a method for recapitulating a tauopathy,
comprising the following steps: (a) providing the cell of the present invention; (b) culturing said
cell under conditions to allow expression of tau protein having abnormal conformation."

Merck Sharp & Dohme Corp.

Patent Issued for Protective Vaccine Based on Staphylococcus Aureus
SA2451 Protein (USPTO 9527892)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness
& Wellness Week -- From Alexandria, Virginia, NewsRx journalists report that a patent by the
inventors McNeely, Tessie (Gwynedd Valley, PA); Montgomery, Donna Lorraine (Chalfont,
PA); Cope, Leslie (Hatfield, PA); Joshi, Amita (Lansdale, PA); Pancari, Gregory P.
(Doylestown, PA); Fan, Hongxia (North Wales, PA), filed on October 26, 2012, was published
online on December 27, 2016.

The patent's assignee for patent number 9527892 is Merck Sharp & Dohme Corp.
(Rahway, NJ).

News editors obtained the following quote from the background information
supplied by the inventors: "Staphylococcus aureus is a bacterial pathogen responsible for a wide
range of diseases and conditions, ranging from minor skin infections to serious life-threatening
wound infections, bacteraemia, endocarditis, pneumonia, osteomyelitis and toxic shock
syndrome. While S. aureus commonly colonizes in the nose and skin of healthy humans, often
causing only minor infections (e.g., pimples, boils), it can also cause systemic infections.
Examples of diseases and conditions caused by S. aureus include bacteremia, infective
endocarditis, folliculitis, furuncle, carbuncle, impetigo, bullous impetigo, cellulitis,
botryomycosis, toxic shock syndrome, scalded skin syndrome, central nervous system infections,
infective and inflammatory eye disease, osteomyelitis and other infections of joints and bones,
and respiratory tract infections. (The Staphylococci in Human Disease, Crossley and Archer

"Staphylococcus aureus is a nosocomial as well as a community-acquired pathogen
which causes several diseases ranging from. See Lowy et al., 1998, N. Engl. J. Med. 339:520-
32. The worldwide growing incidence of staphylococcal infections is strongly related to the
increased use of surgical devices and a growing number of immunocompromised patients. The
situation has become more serious since the increased use of antibiotics led to the emergence of

"Information concerning S. aureus polypeptide sequences has been obtained from sequencing the S. aureus genome. See Kuroda et al., 2001, Lancet 357:1225-1240; Baba et al., 2000, Lancet 359:1819-1827; Gill et al., 2005, J. Bacteriol. 187:2426-2438 and European Patent Publication EP 0 786 519. To some extent, bioinformatics has been employed in efforts to characterize polypeptide sequences obtained from genome sequencing. See, e.g., European Patent Publication EP 0 786 519 and U.S. Pat. No. 6,593,114.

"Techniques such as those involving display technology and sera from infected patients have also been used in an effort to help identify genes coding for potential antigens. See, e.g., International Publication Nos. WO 01/98499 and WO 02/059148; and Etz et al., 2002, Proc. Natl. Acad. Sci. USA 99:6573-6578. Numerous staphylococcal surface proteins have been identified so far using recently adopted technologies, like proteomics (see Brady et al., 2006, Infect. Immun. 74:3415; Gatlin et al., 2006, Proteomics 6:1530; Pieper et al., 2006, Proteomics 6:4246; Vytvytska et al., 2002, Proteomics 2:580; Nandakumar et al., 2005, J. Proteome Res. 4:250) or protein selection methods based on expression libraries (see Clarke et al., 2006, J. Infect. Dis. 193:1098; Etz et al., 2002, Proc. Natl. Acad Sci. USA 99:6573-8; Weichhart et al., 2003, Infect. Immun. 71:4633; and Yang et al., 2006, Vaccine 24:1117).

"Vaccines consisting of one or more antigenic determinants can provide protection against lethal challenge with S. aureus in mice. See Stranger-Jones et al., 2006, Proc. Natl. Acad. Sci. USA 103:16942-7 and Kuklin et al., 2006, Infect. Immun. 74:2215. Recombinantly expressed polypeptides can readily be made, purified, and formulated as vaccines. Additionally, recombinant proteins can be combined with additional components to make multicomponent polypeptide vaccines that induce a spectrum of immune responses. Despite this, there are no reported protein based vaccines for staphylococcal infections in humans or animals to date. Thus, there remains a need for immunogens that can provide protective immunity against Staphylococcal infections in human and/or animals."

As a supplement to the background information on this patent, NewsRx correspondents also obtained the inventors' summary information for this patent: "It is shown herein that SA2451-related polypeptides can provide protective immunity against S. aureus infection in a relevant animal model system. Accordingly, one aspect of the invention provides a composition comprising an immunologically effective amount of a polypeptide that is at least 95% identical to a SA2451 polypeptide (represented by SEQ ID NO:1) or a fragment of the polypeptide and a pharmaceutically acceptable carrier. In embodiments of the invention, the polypeptide is not SEQ ID NO:1 and it is at least 98% identical to SEQ ID NO:1. In more preferred embodiments, the polypeptide is at least 98% identical to SEQ ID NO:1.

"Also provided by the invention are compositions as described above, which further comprise one or more additional S. aureus antigens or one or more additional antigens from another Staph species, such as S. epidermidis. The compositions of the invention may further comprise an adjuvant.

"The present invention is further related to a method of inducing a protective immune response in a patient against an S. aureus infection comprising the steps of
administering to the patient an immunologically effective amount of any of the compositions or vaccines described herein. The compositions are administered to a patient in need thereof, wherein the patient is human or a non-human mammal such as a cow. In some embodiments of the methods described herein, the compositions are given to a patient who suffers from weakened immunity, has received a foreign body implant or is on renal dialysis.

"Also provided by the invention is the use of a polypeptide that is at least 95% identical to SEQ ID NO:1 or a fragment of the polypeptide in the manufacture of a medicament for inducing a protective immune response in a patient against S. aureus infection or the use of the compositions herein for inducing protective immunity against S. aureus.

"Further provided by the invention is a method of conferring passive immunity to S. aureus infection in a patient comprising administering to the patient one or more antibodies that specifically bind to a polypeptide of SEQ ID NO:1."

For additional information on this patent, see: McNeely, Tessie; Montgomery, Donna Lorraine; Cope, Leslie; Joshi, Amita; Pancari, Gregory P.; Fan, Hongxia. Protective Vaccine Based on Staphylococcus Aureus SA2451 Protein. U.S. Patent Number 9527892, filed October 26, 2012, and published online on December 27, 2016. Patent Issued for Quinazoline Analogs as Receptor Tyrosine Kinase Inhibitors (USPTO 9527865)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A patent by the inventors Wallace, Eli (Lyons, CO); Topalov, George (Superior, CO); Lyssikatos, Joseph (Superior, CO); Buckmelter, Alexandre (Superior, CO); Zhao, Qian (Superior, CO), filed on September 7, 2012, was published online on December 27, 2016, according to news reporting originating from Alexandria, Virginia, by NewsRx correspondents.

Patent number 9527865 is assigned to Array BioPharma Inc. (Boulder, CO).

The following quote was obtained by the news editors from the background information supplied by the inventors: "This invention relates to novel inhibitors of type I receptor tyrosine kinases and related kinases, pharmaceutical compositions containing the inhibitors, and methods for preparing these inhibitors. The inhibitors are useful for the treatment of hyperproliferative diseases, such as cancer and inflammation, in mammals and especially in humans.

"The type I receptor tyrosine kinase family consists of four closely related receptors: EGFR (ErbB1 or HER1), ErbB2 (HER2), ErbB3 (HER), and ErbB4 (HER4) (Reviewed in
Riese and Steprn, Bioessays (1998) 20:41-48, Olayioye et al., EMBO Journal (2000) 19:3159-3167 and Schlessinger, Cell (2002) 110:669-672. These are single pass transmembrane glycoprotein receptors containing an extracellular ligand binding region and an intracellular signaling domain. In addition, all receptors contain an intracellular active tyrosine kinase domain with the exception of ErbB3 whose kinase domain does not exhibit enzymatic activity. These receptors transmit extracellular signals through the cytosol to the nucleus upon activation. The activation process is initiated by ligand binding to the extracellular domain of the receptor by one of a number of different hormones. Upon ligand binding, homo- or heterodimerization is induced which results in the activation of the tyrosine kinase domains and phosphorylation of tyrosines on the intracellular signaling domains. Since no known ligand for ErbB2 has been described and ErbB3 lacks an active kinase domain, these receptors must heterodimerize to elicit a response. The phosphotyrosines then recruit the necessary cofactors to initiate several different signaling cascades including the ras/raf/MEK/MAPK and PI3K/AKT pathways. The precise signal elicited will depend on what ligands are present since the intracellular signaling domains differ as to what pathways are activated. These signaling pathways lead to both cell proliferation and cell survival through inhibition of apoptosis.

"The type I tyrosine kinase receptor family have been an active area of anti-cancer research (Reviewed in Mendelsohn and Baselga, Oncogene (2000) 19:6550-6565 and Normanno et al., Endocrine-Related Cancer (2003) 10:1-21). Several inhibitors of the EGFR and the ErbB2 signaling pathway have demonstrated clinical efficacy in cancer treatment. Herceptin, a humanized version of anti-ErbB2 monoclonal antibody, was approved for use in breast cancer in the United States in 1998. Iressa and Tarceva are small molecule inhibitors of EGFR that are expected to be commercially available. In addition, several other antibodies and small molecules that target the interruption of the type I tyrosine kinase receptor signaling pathways are in clinical and preclinical development. For example, IMC-225, which is a humanized antibody against the extracellular domain of EGFR demonstrated efficacy and will likely be approved."

In addition to the background information obtained for this patent, NewsRx journalists also obtained the inventors' summary information for this patent: "This invention provides compounds, methods to produce these compounds, and pharmaceutical compositions containing the compounds that inhibit type I receptor tyrosine kinases. Such compounds, generally referred to as quinazoline analogs, have utility as therapeutic agents for diseases that can be treated by the inhibition of type I receptor tyrosine kinases. They may also act as inhibitors of serine, threonine, and dual specificity kinases inhibitors. In general, the invention relates to quinazoline derivatives of general Formula I:

"##STR00002## wherein A is bonded to at least one of the carbons at positions 5, 6, 7 or 8 of the bicyclic ring and wherein the bicyclic ring is substituted by zero, one or two independent R.sup.3 groups; X is N, CH, CF or C--CN; A is Q or Z; Q is

or R\textsuperscript{8} and R\textsuperscript{10} together with the atoms to which they are attached may be independently joined to complete a 3 to 10 membered cycloalkyl ring or heterocycloalkyl ring optionally containing one or more additional heteroatoms selected from the group consisting of O, S, SO, SO\textsubscript{2} and NR\textsuperscript{6}, wherein each ring carbon may be optionally substituted with one to three groups independently selected from the group consisting of halogen, C\textsubscript{1}-C\textsubscript{10} alkyl, C\textsubscript{2}-C\textsubscript{10} alkenyl, C\textsubscript{2}-C\textsubscript{10} alkynyl, C\textsubscript{3}-C\textsubscript{10} cycloalkyl, C\textsubscript{3}-C\textsubscript{10} cycloalkylalkyl, cyano, nitro, trifluoromethyl, difluoromethoxy, trifluoromethoxy, azido, aryl, OR\textsuperscript{8}, NR\textsuperscript{6}R\textsuperscript{8}, SR\textsuperscript{6}, heteroaryl, aryalkyl, heteroaryalkyl, heterocyclyl, partially unsaturated heterocyclyl and heterocyclylalkyl, provided said ring does not contain two adjacent 0 or two adjacent S atoms.

"The invention may also be directed to pharmaceutically acceptable prodrugs, pharmaceutically active metabolites, and pharmaceutically acceptable salts of the compound of general Formula I. Methods of making the compounds of Formula I are also described.

"In a further aspect, the present invention provides compounds that inhibit the activity of type I receptor tyrosine kinases such as EGFR, ErbB2, ErbB3, ErbB4, VEGFR2, Flt3
and FGFR, comprising compounds of Formula I.

"In a further aspect, the present invention provides a method of treating diseases or medical conditions mediated by type I receptor tyrosine kinases which comprises administering to a warm-blooded animal an effective amount of a compound of Formula I, or a pharmaceutically acceptable salt or in vivo cleavable prodrug thereof.

"In a further aspect, the present invention provides a method of inhibiting the production of type I receptor kinases which comprises administering to a warm-blooded animal an effective amount of a compound of Formula I, or a pharmaceutically acceptable salt or in vivo cleavable prodrug thereof.

"In a further aspect, the present invention provides a method of providing type I receptor kinase inhibitory effect comprising administering to a warm-blooded animal an effective amount of a compound of Formula I, or a pharmaceutically acceptable salt or in vivo cleavable prodrug thereof.

"In a further aspect, the present invention provides treating or preventing a type I receptor kinase mediated condition, comprising administering an amount of a compound effective to treat or prevent said type I receptor kinase-mediated condition or a pharmaceutical composition comprising said compound, to a human or animal in need thereof, wherein said compound is a compound of Formula I, or a pharmaceutically-acceptable salt or in vivo cleavable prodrug thereof. The type I receptor kinase mediated condition that can be treated according to the methods of this invention includes hyperproliferative disorders, such as cancer of the head and neck, lung, breast, colon, ovary, bladder, stomach, kidney, skin, pancreas, leukemias, lymphomas, esophagus, uterus or prostate, among other kinds of hyperproliferative disorders.

"The compounds of Formula I may be used advantageously in combination with other known therapeutic agents.

"The invention also relates to pharmaceutical compositions comprising an effective amount of an agent selected from compounds of Formula I or a pharmaceutically acceptable prodrug, pharmaceutically active metabolite, or pharmaceutically acceptable salt thereof.

"Additional advantages and novel features of this invention shall be set forth in part in the description that follows, and in part will become apparent to those skilled in the art upon examination of the following specification, or may be learned by the practice of the invention. The advantages of the invention may be realized and attained by means of the instrumentalities, combinations, compositions, and methods particularly pointed out in the appended claims.”

Siemens Healthcare Diagnostics Inc.

**Patent Issued for Reagents and Methods for Detecting HCV (USPTO 9528163)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- From Alexandria, Virginia, NewsRx journalists report that a patent by the inventors Uzgiris, Arejas (Berkeley, CA); Pandit, Sunil (Concord, CA); Palmer, Lance (Plainsboro, NJ), filed on June 20, 2012, was published online on December 27, 2016.

The patent's assignee for patent number 9528163 is Siemens Healthcare Diagnostics Inc. (Tarrytown, NY).

News editors obtained the following quote from the background information supplied by the inventors: "Hepatitis C virus (HCV) infection is a major health problem that leads to chronic liver disease, such as cirrhosis and hepatocellular carcinoma, in a substantial number of infected individuals, estimated to be 2-15% of the world's population. There are an estimated 3.9 million infected people in the United States alone, according to the U.S. Center for Disease Control, roughly five times the number of people infected with the human immunodeficiency virus (HIV). According to the World Health Organization, there are more than 170 million infected individuals worldwide, with at least 3 to 4 million people being infected each year. Once infected, about 20% of people clear the virus, but the rest harbor HCV for the rest of their lives. Ten to twenty percent of chronically infected individuals eventually develop liver-destroying cirrhosis or cancer. The viral disease is transmitted parenterally by contaminated blood and blood products, contaminated needles, or sexually, and vertically from infected mothers or carrier mothers to their off-spring."

As a supplement to the background information on this patent, NewsRx correspondents also obtained the inventors' summary information for this patent: "The present disclosure relates to oligonucleotide sequences for amplification primers and their use in performing nucleic acid amplifications of HCV, in particular regions that encode the NS3 polypeptide. In some embodiments the primers are used in nested PCR methods for the detection or sequencing of HCV NS3. The oligonucleotide sequences are also provided assembled as kits that can be used to detect or sequence HCV NS3.

"In some embodiments, isolated oligonucleotide amplification primers comprise a nucleic acid sequence selected from the group consisting of SEQ ID NOS: 1-20, complementary sequences thereof, active fragments thereof, and combinations thereof.

"In some embodiments, collections of primers for amplifying a portion of HCV NS3 1a genomic sequence are provided which comprise one or more forward primers selected from the group consisting of SEQ ID NO: 1, SEQ ID NO: 2, SEQ ID NO: 3, SEQ ID NO: 4, SEQ ID NO: 5, active fragments thereof, and combinations thereof; and one or more reverse primers selected from the group consisting of SEQ ID NO: 6, SEQ ID NO: 7, SEQ ID NO: 8, SEQ ID NO: 9, SEQ ID NO: 10, active fragments thereof, and combinations thereof.

"In some embodiments, collections of primers for amplifying a portion of HCV NS3 1b genomic sequence are provided which comprise one or more forward primers selected from the group consisting of SEQ ID NO: 11, SEQ ID NO: 12, SEQ ID NO: 13, SEQ ID NO: 14, SEQ ID NO: 15, active fragments thereof, and combinations thereof; and one or more reverse primers selected from the group consisting of SEQ ID NO: 16, SEQ ID NO: 17, SEQ ID NO: 18, SEQ ID NO: 19, SEQ ID NO: 20, active fragments thereof, and combinations thereof.

"In some embodiments, kits for amplifying HCV NS3 by nested PCR are provided that comprise one of the aforementioned collections of primers as outer primers in combination
with a suitable set of inner primers.

"In some embodiments, methods of amplifying HCV NS3 in a sample are provided that comprise contacting a sample with one of the aforementioned collections of primers as outer primers and submitting the resulting mixture to a first nucleic acid amplification reaction. In some embodiments, these methods further comprise contacting a product from the first nucleic acid amplification reaction with a set of inner primers and submitting the resulting mixture to a second nucleic acid amplification reaction. In some embodiments, these methods further comprise sequencing a product from the second nucleic acid amplification reaction to detect an HCV NS3 polymorphism."

**Glycotope GmbH**

**Patent Issued for Recombinant Human Follicle-Stimulating Hormone (USPTO 9527899)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A patent by the inventors Goletz, Steffen (Berlin, DE); Stockl, Lars (Berlin, DE), filed on August 4, 2011, was published online on December 27, 2016, according to news reporting originating from Alexandria, Virginia, by NewsRx correspondents.

Patent number 9527899 is assigned to Glycotope GmbH (Berlin, DE).

The following quote was obtained by the news editors from the background information supplied by the inventors: "Gonadotropins are a group of protein hormones which regulate gonadal function in the male and female and thereby play an important role in human fertility. They are secreted by gonadotrope cells of the pituitary gland of vertebrates after stimulation by the gonadotropin-releasing hormone (GnRH). Gonadotropins are heterodimeric glycoproteins including follicle stimulating hormone (FSH), luteinizing hormone (LH) and chorionic gonadotropin (CG). The gonadotropins share identical alpha-subunits but comprise different beta-subunits which ensure receptor binding specificity.

"FSH comprises a 92 amino acid alpha-subunit and a 111 amino acid beta-subunit which confers specific binding to the FSH receptor. Both subunits of the natural protein are modified by glycosylation. The alpha-subunit is naturally glycosylated at Asn52 and Asn78 and the beta-subunit at Asn7 and Asn24. Both subunits are produced in the cells as precursor proteins and then processed and secreted. FSH regulates the development, growth, pubertal maturation, and reproductive processes of the body. In particular, it stimulates the maturation of germ cells and thus is involved in spermatogenesis and folliculogenesis.

"Folliculogenesis is induced by FSH, for example, by binding of FSH to FSH receptors on the surface of granulosa cells. FSH receptors are G protein-coupled receptors
which activate the coupled G protein upon binding of FSH. The G protein in turn activates
adenyl cyclase, resulting in the production of cAMP, a second messenger molecule. The
increasing cAMP concentration in the cell activates several downstream targets, in particular
cAMP dependent protein kinases, which then lead to the synthesis of progesterone and estradiol.
The progesterone and estradiol is secreted by the granulosa cells, inducing folliculogenesis.
Upon stimulation of the granulosa cells by FSH, they also release inhibin-B which forms a
negative feedback loop, inhibiting the production and secretion of FSH in the pituitary gland.
Inhibin-B was shown to be a good surrogate marker for the ovarian stimulation by FSH.

"FSH is widely used in the treatment of infertility, either alone or in combination
with other agents, in particular LH. In the art, generally FSH purified from post-menopausal
human urine (urinary FSH) or FSH recombinantly produced by Chinese hamster ovary (CHO)
cells has been used for human treatment. However, there is considerable heterogeneity
associated with FSH preparations due to different isoforms present. Individual FSH isoforms
exhibit identical amino acid sequences but differ in the extent and nature of their glycosylation.
Particular isoforms are characterized by heterogeneity of the carbohydrate branch structures and
differing amounts of sialic acid (a negatively charged terminal monosaccharide unit)
incorporation, both of which influence the specific bioactivity of the isoform. Thus, the
glycosylation pattern of the FSH has a significant influence on its biological activity.

"However, urinary FSH from different donors and different preparations can
significantly vary in its carbohydrate structures, resulting in a high batch-to-batch variation.
There are also safety concerns regarding the presence of viruses in the urinary products.
Furthermore, FSH obtained from CHO cells exhibits a glycosylation pattern specific for these
hamster cells which is not identical to human glycosylation patterns. These differences result in
varying biological activities and adverse effects of the obtained FSH and thus, of the
pharmaceutical preparations which are to be administered to the patient.

"In view of this, it is one object of the present invention to provide improved FSH
preparations.

"Furthermore, it is an object of the present invention to provide FSH preparations
with novel therapeutic or pharmacological characteristics.

"Furthermore, it is an object of the present invention to provide FSH preparations
which have an improved glycosylation pattern."

In addition to the background information obtained for this patent, NewsRx
journalists also obtained the inventors' summary information for this patent: "The present
inventors have found that improved FSH preparations obtained from human cells which
preferably have been selected for an optimized glycosylation are able to induce the secretion of
sex steroids such as estradiol and progesterone at lower concentrations than corresponding FSH
preparations obtained from human urine or CHO cells. Therefore, the FSH preparations
according to the present invention have surprising characteristics which are useful in therapy.

"The present invention provides, in a first aspect, a recombinant FSH preparation,
wherein the recombinant FSH in the preparation has a glycosylation pattern comprising one or
more of the following characteristics: (i) a relative amount of glycans carrying bisecting N-
acetylgalactosamine (bisGlcNAc) of at least 20%; (ii) a relative amount of glycans carrying
fucose of at least 30%; and/or (iii) a relative amount of 2,6-coupled sialic acid of at least 30%;
and/or (iv) it is a diverse glycosylation pattern.

"In a second aspect, the present invention provides a recombinant FSH preparation
obtainable by production in human cells or a human cell line, preferably in the cell line GT-5s
(DSM ACC3078, deposited on Jul. 28, 2010). It was found that FSH produced in a respective
cell line results in an improved glycosylation profile as is described above and below.
"Also provided is a pharmaceutical composition, comprising the recombinant FSH according to the present invention.

"Furthermore, the present invention pertains to the recombinant FSH preparation or the pharmaceutical composition according to the present invention for use in infertility treatment.

"Furthermore, the present invention pertains to the recombinant FSH preparation or the pharmaceutical composition according to the present invention for inducing and/or stimulating the secretion of sex steroids also independent of cAMP.

"Some experiments have shown that the low concentration effects of the FSH according to the invention are in certain circumstances independent of cAMP signaling in the target cells. Thus, the experiments suggest that the improved FSH preparations according to the present invention may induce the secretion of sex steroids such as progesterone at concentrations without an increase of cAMP secretion. Therefore, it is believed that certain embodiments of the improved FSH preparations according to the present invention are capable of inducing a signal transduction pathway leading to sex steroid secretion which is different from the known signal transduction pathway using cAMP as second messenger described for the commonly used FSH preparations.

"Furthermore, the present invention pertains to the recombinant FSH preparation or the pharmaceutical composition according to the present invention for stimulating or co-stimulating germ cell maturation by a biological process which is independent of cAMP signaling.

"Furthermore, the present invention pertains to the recombinant FSH preparation or the pharmaceutical composition according to the present invention for inducing and/or stimulating the secretion of sex steroids at FSH concentrations at which no significant cAMP release is induced.

"Other objects, features, advantages and aspects of the present invention will become apparent to those skilled in the art from the following description and appended claims. It should be understood, however, that the following description, appended claims, and specific examples, which indicate preferred embodiments of the application, are given by way of illustration only. Various changes and modifications within the spirit and scope of the disclosed invention will become readily apparent to those skilled in the art from reading the following."

Keywords for this news article include: Inhibins, CHO Cells, Cell Line, Estradiol, Estrogens, Amino Acids, Sex Hormones, Glycotope GmbH, Vaginal Agents, Endocrine Cells, Granulosa Cells, Endocrine Glands, Endocrine System, Gonadal Hormones, Ovarian Follicle, Peptide Hormones, Peptide Proteins, Pituitary Hormones, Drugs and Therapies, Vaginal Preparations.

TOPHARMAN SHANGHAI CO., LTD.

Patent Issued for Salt and Polymorph of Pyrazolopyrimidinone Compound, and Pharmaceutical Composition Containing the Same, Preparation Method and Use (USPTO 9527849)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- TOPHARMAN SHANGHAI CO., LTD. (Shanghai, CN) has been issued patent number 9527849, according to news reporting originating out of Alexandria, Virginia, by NewsRx editors.

The patent's inventors are Li, Jianfeng (Shanghai, CN); Tian, Guanghui (Shanghai, CN); Wang, Zhen (Shanghai, CN); Suo, Jin (Shanghai, CN); Jiang, Xiangrui (Shanghai, CN); Liu, Zheng (Shanghai, CN); Yang, Xiaojun (Shanghai, CN); Xie, Zhu (Shanghai, CN); Zhao, Xianguo (Shanghai, CN); Zhu, Weiliang (Shanghai, CN); Jiang, Hualiang (Shanghai, CN); Shen, Jingshan (Shanghai, CN).

This patent was filed on August 14, 2012 and was published online on December 27, 2016.

From the background information supplied by the inventors, news correspondents obtained the following quote: "It discloses the use of a class of pyrazolo[4,3-d]pyrimidine-7-one derivatives as cGMP-specific phosphodiesterase inhibitors to treat erectile dysfunction in the international application WO9428902 (CN1124926A). Then in WO0227848 (CN1325398T), it discloses another class of pyrazolo[4,3-d]pyrimidine-7-one derivatives having a potent inhibitory activity for type V of phosphodiesterase (PDE5), which can be used for the treatment of diseases relevant to PDE enzymes.

"A series of compounds having inhibitory activity against PDE5 are disclosed in the international application WO2007056955, which exhibit extremely high activity and selectivity for the PDE5 enzyme in the screening test in vitro of enzyme inhibitors and in which the compound 1-methyl-5-2-propoxy-5-[1-methyl-1-(2-pyrrolidin-1-yl)ethyl]aminosulfonyl-yl phenyl-3-propyl-1,6-dihydro-7H-pyrazolo[4,3-d]pyrimidin-7-one (compound Z, in the Example 80 in WO2007056955) represented by the following formula is included:

"##STR00002##

"However, the compound will significantly degrade at high temperature and in bright light, and has poor chemical stability. Therefore it is particularly important to develop a stable form of the compound Z. Moreover, the compound has disadvantage with poor water-solubility and is difficult to be dissolved, which will cause some negative impact on the pharmaceutical preparation process. On the other hand, the compound itself has a pungent odor, which also has a negative impact on the application as pharmaceutical preparations for human. Therefore, the object of the invention is to develop a form of compound Z suitable for preparing the medicine, which should have good stability, high water solubility, low hygroscopicity, no pungent odor and so on.

"The physical properties of pharmaceutical compounds and salts thereof, as well as their crystals and amorphous thereof have a greater impact on the bioavailability of the drugs, the purity of the drug substance, prescription of preparations etc. So in the pharmaceutical development, it is necessary to study what kinds of salts, crystalline forms, amorphous of the compounds are best to be as a drug. That is, since the above-described physical properties depend on the characteristics of the various compounds, it is usually difficult to predict pharmaceutically acceptable salts, crystals, and amorphousness of the original substances having
good properties; therefore there is a sustained need to study a variety of compounds.

"Thus, one object of the invention is to provide various salts, crystals and amorphousness of compound Z. In addition, another object of the invention is to provide crystals and amorphousness of compounds (I).

"Based on the deeply study on synthesis and separation of various salts and crystals of the compound Z, and researching work on the physical and chemical properties thereof, the present inventors found the forms of salts, crystals and solvate of compound Z having excellent physical properties, which can be used as raw material for medicine directly or intermediates for the manufacture of pharmaceutical raw materials, thereby completing the present invention."

Supplementing the background information on this patent, NewsRx reporters also obtained the inventors' summary information for this patent: "The present invention relates to a new salt of 1-methyl-5-2-propoxy-5-[1-methyl-1-(2-pyrrolidin-1-yl)ethyl]aminosulfon-yl]phenyl-3-propyl-1,6-dihydro-7H-pyrazolo[4,3-d]pyrimidin-7-one (compound Z), and pharmaceutically acceptable polymorph, solvate, hydrate, dehydrate, co-crystal, anhydrid, or amorphous form thereof, the pharmaceutical compositions and a pharmaceutical unit dosage form containing the same. The invention further relates to co-crystals or complexes of 1-methyl-5-2-propoxy-5-[1-methyl-1-(2-pyrrolidin-1-yl)ethyl]aminosulfon-yl]phenyl-3-propyl-1,6-dihydro-7H-pyrazolo[4,3-d]pyrimidin-7-one and pharmaceutical compositions containing the same. The present invention also relates to a process for the preparation thereof.

"According to one aspect of the present invention, an object of the present invention is to provide a salt of compound 1-methyl-5-2-propoxy-5-[1-methyl-1-(2-pyrrolidin-1-yl)ethyl]aminosulfon-yl]phenyl-3-propyl-1,6-dihydro-7H-pyrazolo[4,3-d]pyrimidin-7-one and the cocrystallization form thereof, having high stability, low moisture absorption, high purity, and being more readily formulated in pharmaceutical processing.

"According to one aspect of the present invention, A further object of the present invention is to provide a compound represented by formula (I) (i.e. the acid addition salts of compound 1-methyl-5-2-propoxy-5-[1-methyl-1-(2-pyrrolidin-1-yl)ethyl]aminosulfon-yl]phenyl-3-propyl-1,6-dihydro-7H-pyrazolo[4,3-d]pyrimidin-7-one and acid X) and pharmaceutically acceptable polymorph, solvate, hydrate, dehydrate, co-crystal, anhydrid, or amorphous form thereof:

"Wherein, X includes, but not limited to, organic or inorganic acid. For example, the organic acid includes, but not limited to, maleic acid, succinic acid, citric acid, tartaric acid, fumaric acid, formic acid, acetic acid, propionic acid, malonic acid, oxalic acid, benzoic acid, phthalic acid, methanesulfonic acid, benzenesulfonic acid, toluenesulfonic acid, naphthalenesulfonic acid, 1,5-naphthalenedisulfonic acid, camphamic acid, camphorsulfonic acid, salicylic acid, acetyl salicylic acid, aspartic acid, glutamic acid, lactic acid, gluconic acid, vitamin C acid, gallic acid, mandelic acid, malic acid, sorbic acid, trifluoroacetic acid, taurine, high taurine, 2-hydroxy ethyl sulfonic acid, cinnamic acid. The inorganic acid includes, but not limited to, hydrochloric acid, hydrobromic acid, hydroiodic acid, sulfuric acid, nitric acid, phosphoric acid, perchloric acid; and the similar protic acid.

"Wherein, X is preferably selected from the group consisting of an organic acid, hydrochloric acid, nitric acid and sulfuric acid.

"X is more preferably selected from the group consisting of maleic acid, succinic acid, citric acid, methanesulfonic acid, hydrochloric acid, nitric acid and sulfuric acid.

"X is more preferable maleic acid or succinic acid.

"The most preferable compound represented by formula (I) is the crystalline form A
of maleate of compound Z.

"The term of 'salt' described herein includes the pharmaceutically acceptable salts and pharmaceutically unacceptable salts. The pharmaceutically unacceptable salts are not preferable to be administrated to the patient, however they may be used to provide the pharmaceutical intermediates and a pharmaceutical bulk drug form.

"The term of 'pharmaceutically acceptable salts' or 'pharmaceutically acceptable acid addition salt' refers to salts prepared by using different pharmaceutically acceptable acid. The salts include, but not limited to, organic salts and inorganic salts, preferably, which are the salts of maleic acid, succinic acid, citric acid, methanesulfonic acid, hydrochloric acid, nitric acid or sulfuric acid, and is most preferably the salts of maleic acid or succinic acid.

"Another embodiment of the present invention relates to pharmaceutical compositions and dosage forms containing therapeutically or prophylactically effective amount of the pharmaceutically acceptable salts of compound 1-methyl-5-2-propoxy-5-[1-methyl-1-(2-pyrrolidin-1-yl)ethyl]aminosulfon-y]phenyl-3-propyl-1,6-dihydro-7H-pyrazolo[4,3-D]pyrimidin-7-one, or a polymorph, solvate, hydrate, dehydrate, co-crystal, anhydrid, or amorphous form.

"Optionally, the acid addition salt of 1-methyl-5-2-propoxy-5-[1-methyl-1-(2-pyrrolidin-1-yl)ethyl]aminosulfon-y]phenyl-3-propyl-1,6-dihydro-7H-pyrazolo[4,3-D]pyrimidin-7-one can absorb moisture to form a hydrate with planar water by placing in the air or by recrystallization. Such acid addition salts containing such moisture are still included in the present invention.

"The solvent in 'solvate' in the present invention may be any solvent used in the manufacture of the salts and crystallization and is not particularly limited. Specifically, for example the solvate may be hydrate, alcoholate, acetone solvate or toluene solvate, and preferably hydrate or alcoholate.

"A further embodiment of the invention relates to the preparation method of the pharmaceutical composition and dosage form comprising a therapeutically or prophylactically effective amount of the pharmaceutically acceptable salt of 1-methyl-5-2-propoxy-5-[1-methyl-1-(2-pyrrolidin-1-yl)ethyl]aminosulfon-y]phenyl-3-propyl-1,6-dihydro-7H-pyrazolo[4,3-D]pyrimidin-7-one, or a polymorph, solvate, hydrate, dehydrate, co-crystal, anhydrid, or amorphous form thereof. The particular preparation method is as follows:

"1. Preparation Method for the Salt of 1-methyl-5-2-propoxy-5-[1-methyl-1-(2-pyrrolidin-1-yl)ethyl]aminosulfon-y]phenyl-3-propyl-1,6-dihydro-7H-pyrazolo[4,3-D]pyrimidin-7-one (Compound Represented by Formula I)

"Referring to Preparation Example 80 of WO2007056955, the compound 1-methyl-5-2-propoxy-5-[1-methyl-1-(2-pyrrolidin-1-yl)ethyl]aminosulfon-y]phenyl-3-propyl-1,6-dihydro-7H-pyrazolo[4,3-D]pyrimidin-7-one (compound Z) is prepared. The compound represented by formula (I) can be prepared as the salt by reacting the corresponding acid with compound Z, the method of the present invention is as follows:

"Method I:

"1) Dissolving compound Z in a first solvent to form a solution a; 2) Dissolving a corresponding acid X in a second solvent to form a solution b; 3) Adding the solution a to the solution b, or adding the solution b to the solution a, so as to obtain a mixed solution, and then separating the salt of the compound Z from the mixed solution (i.e., a compound represented by formula I); Method II: 1) Dissolving compound Z in a first solvent to form a solution a; 2) Adding a corresponding acid X directly to the solution a, and then separating the salt of the compound Z from the solution (i.e., a compound represented by formula I); Method III: 1) Dissolving a corresponding acid X in a second solvent to form a solution b; 2) Adding
compound Z directly into the solution b, and then separating the salt of the compound Z from the solution (i.e., a compound represented by formula I);

"In the above-described method, the first and second solvents may be each independently selected from water, non-aqueous solvent or the mixed solvent thereof, more particularly, include water, alcohols, ethers, esters, hydrocarbons, ketones. The first and second solvents may each independently select from one or more of water; esters (such as ethyl acetate, methyl acetate, propyl acetate, butyl acetate, methyl formate, ethyl formate, propyl formate, butyl formate); alcohols (such as methanol, ethanol, propanol, isopropanol, butanol, ethylene glycol, propylene glycol); ethers (such as diethyl ether, dipropyl ether, diisopropyl ether, petroleum ether, ethylene glycol monomethyl ether, ethylene glycol monoethyl ether, ethylene glycol monopropyl ether, ethylene glycol dimethyl ether, ethylene glycol diethyl ether, propylene glycol monomethyl ether, propylene glycol monoethyl ether, propylene glycol dimethyl ether, tetrahydrofuran, dioxane, dimethoxyethane, diethylene glycol dimethyl ether); ketones (such as acetone, butanone, N-methylpyrrolidone, diethyl ketone); hydrocarbons (such as n-pentane, n-hexane, heptane); aromatic hydrocarbons (such as toluene, benzene, xylene, chlorobenzene, dichlorobenzene); alkylenes (such as methylene chloride, chloroform or 1,2-dichloroethane, carbon tetrachloride); acids (acetic acid, propionic acid); and nitriles (such as acetonitrile, propionitrile).

"The definition of the corresponding acid is same as the definition of X in formula (I).

"The reaction temperature may be varied according to the reagents or solvents, etc., and is generally from -20.degree. C. to 200.degree. C., preferably from 0.degree. C. to 100.degree. C.

"The reaction time is not limited and usually from 10 minutes to 10 hours.

"2. The Preparation Method for Various Crystalline Forms of Compound Z (Compound Represented by Formula I)

"Another aspect of the present invention provides a polymorph and solvate of the salt of Compound Z (Compound represented by formula I) and a preparation method thereof. In the mentioned method, the seed crystal may be added as necessary in the process. The 'seed crystal' herein refers to 'seed' of the compound represented by formula (I) or a homemade crystal material of the compound represented by formula (I), which is used to induce crystallization.

"Method I

"1) Dissolving compound Z in a third solvent to form a solution C; 2) Dissolving a corresponding acid X in a fourth solvent to form a solution D; 3) Adding the solution C into the solution D, or adding the solution D into the solution C, or adding the corresponding acid X directly into the solution C, so as to obtain a mixed solution E; 4) Optionally, adding a fifth solvent into the mixed solution E; 5) Precipitating the target crystal by standing, stirring or adding corresponding seed crystal into the solution prepared in step 4); Method II 1) Dissolving the salt of compound Z (compound represented by formula (I)) in the third solvent to form solution F; 2) Optionally, adding the fifth solvent into the solution F; 3) Precipitating the target crystal by standing, stirring or adding corresponding seed crystal into the solution prepared in step 2); Method III 1) Suspending the salt of compound Z (compound represented by formula (I)) in the third solvent to form suspension G; 2) Optionally, adding the fifth solvent into the solution G; 3) Precipitating the target crystal by heating, stirring and cooling the obtained solution, or adding seed crystal into the solution prepared in step 2);

"Wherein, the third solvent, the fourth solvent and the fifth solvent may be same or different. And the definitions of the third, fourth and fifth solvents are same as those of the above first and second solvents. The range of reaction temperature is same as that for preparing
the salt of the compound Z (compound represented by formula I).

"In particular, the preferred method for preparing the crystalline form A of compound Z maleate is as follows:

"Compound Z is suspended in alcohol and heated to 65.\degree\ C., then one equivalent of maleic acid is added therein, and the mixture is heated under temperature of 65.\degree\ C. for 0.5 to 3 hours. Optionally, active carbon is added to perform the decolorizing. And the resulting filtrate solution is allowed to stand or be stirred at room temperature so as to precipitate the solid, after that, the solid precipitate is isolated, i.e. crystalline form A of the compound Z maleate, which may be isolated by conventional means from the reaction mixture.

"3. Characterization of Crystalline Type of the Salt of Compound Z (Compound Represented by Formula I) in the Polymorph

"In general, the diffraction angle (2.\theta.) in X-ray powder diffraction may have a deviation of \pm 0.2.\degree.. Therefore, the following values of the diffraction angle should be understood to include a range of containing a deviation of \pm 0.2.\degree.. Accordingly, the present invention includes not only the crystals which are identically consistent with the X-ray powder diffraction peaks (diffraction angle), and but also the crystals consistent with the peak (diffraction angle) with a deviation of \pm 0.2.\degree..

"(1) Characterization of Crystalline Form A of Compound Z Maleate
"The present invention provides a crystalline form A of compound Z maleate.
"The data of DSC spectrum (FIG. 1) of the crystalline form A of compound Z maleate are as follows:
"The initial value (Onset)=166.164.+-.1.\degree. C., Peak value (Peak)=168.166. +-.1.\degree. C.
"The melting point of the crystalline form A of compound Z maleate is between 162.+-.2.\degree. C. and 163.+-.2.\degree. C.
"The data of X-ray powder diffraction pattern (see FIG. 2) of crystalline form A of maleate of compound Z are as follows (Table 1): the 2.\theta. diffraction angle is used to express X-ray powder diffraction, wherein the crystalline form has diffraction peaks at 6.30.\degree..+-.0.2.\degree., 20.18.\degree..+-.0.2.\degree., 22.30.\degree..+-.0.2.\degree. and 24.02.\degree..+-.0.2.\degree..

"(2) Characterization of the Amorphous Form of Compound Z Maleate
"The present invention provides an amorphous form of compound Z maleate, the X-ray powder diffraction pattern of which is shown in FIG. 3.

"(3) Characterization of the Crystalline Form I of Compound Z Succinate
"The present invention provides a crystalline form I of compound Z succinate.
"The data of DSC spectrum (FIG. 4) of compound Z succinate are as follows:
"The initial value (Onset)=151.214.+-.1.\degree. C., Peak value (Peak)=154.166. +-.1.\degree. C.
"The melting point of the crystalline form I of compound Z succinate is between 148.+-.2.\degree. C. and 149.+-.2.\degree. C.
"The data of X-ray powder diffraction pattern (FIG. 5) of the crystalline form I of compound Z succinate are as follows (Table 2): the 20 diffraction angle is used to express X-ray
powder diffraction, wherein the crystalline form has diffraction peaks at 6.42.degree..+-.0.2.degree., 8.00.degree..+-.0.2.degree., 18.34.degree..+-.0.2.degree. and 24.56.degree..+-.0.2.degree..

"(4) Characterization of the Crystalline Form I of Compound Z Methanesulfonate

"The present invention provides the crystalline form I of compound Z methanesulfonate.

"The data of X-ray powder diffraction pattern (FIG. 6) of the crystalline form I of compound Z methanesulfonate are as follows (Table 3): the 20 diffraction angle is used to express X-ray powder diffraction, wherein the crystalline form has diffraction peaks at 6.62.degree..+-.0.2.degree., 17.94.degree..+-.0.2.degree., 22.24.degree..+-.0.2.degree. and 26.45.degree..+-.0.2.degree..

(8) Characterization of the Crystalline Form IV of Compound Z Hydrochloride

The present invention provides a crystalline form IV of compound Z hydrochloride.

The data of DSC spectrum (FIG. 13) of the crystalline form IV of compound Z hydrochloride are as follows:

The initial value (Onset)=180.050.+-1.0 degree. C., the peak temperature (Peak)=184.333.+-1.0 degree. C.

The initial value (Onset)=196.715.+-1.0 degree. C., the peak temperature (Peak)=199.333.+-1.0 degree. C.

The data of X-ray powder diffraction pattern (FIG. 14) of the crystalline form IV of compound Z hydrochloride are as follows (Table 7): the 2θ. diffraction angle is used to express X-ray powder diffraction, wherein the crystalline form has diffraction peaks at 7.41. degree.+-0.2 degree., 7.64. degree.+-0.2 degree., 17.55. degree.+-0.2 degree. and 25.83. degree.+-0.2 degree..

According to another aspect of the present invention, one object of the present invention is to provide a pharmaceutical composition comprising one or more compounds represented by formula (I) and pharmaceutically acceptable accessories, preferably a pharmaceutical composition comprising maleate, succinate, methanesulfonate, citrate, hydrochloride, sulfate of compound Z, more preferably a pharmaceutical composition comprising crystalline form A of compound Z maleate having a X-ray powder diffraction pattern shown in table 1.

The accessories may be an excipient, a binder, a lubricant, a disintegrating agent, a coloring agent, a corrective, an emulsifier, a surfactant, a solubilizer, a suspending agent, an isotonic agent, a buffering agent, preservatives, an antioxidant, a stabilizer, an absorption accelerators and the like commonly used in the pharmaceutical art, and a suitable combination...
of the foregoing accessories may be used if necessary.

"Preferably, the salts of the compound Z of the present invention may be formulated with at least one pharmaceutical excipient in the oral pharmaceutical composition, each dosage may contain 10 mg to 200 mg of the active ingredient.

"When preparing a solid composition in tablet type, the main active ingredient may be mixed with a pharmaceutical carrier such as starch, lactose, magnesium stearate, etc., or the tablet may be coated with a sugar-coating or other suitable material, or can be treated so as to allow the tablet to have a prolonged or slow releasing function, so that the tablet can release a predetermined amount of the active ingredient in a continuous manner.

"Or, a capsule dosage form can be obtained by mixing the active ingredient with a diluent and filling the resulting mixture into a capsule.

"When using the acid addition salts of the compound Z (compound represented by formula I) of the present invention as therapeutic agents or preventive medicines to treat the above-mentioned diseases, itself (or mixed with pharmaceutically acceptable excipient or diluent etc.) can be orally administered in form of tablet, capsule, granule, powder or syrup etc., or can be non-orally administered in form of injection, injectable powder, sprays or suppositories.

"These formulations may be prepared by conventional methods.

"The usage amount of medicine will be different according to the symptom, age, etc., for example, an adult can be administered 1 to 7 times in one to seven days according to the symptom, the dose is 0.01 mg to 1000 mg, and the administration manner is not limited.

"Another object of the present invention is to provide a use of the compound represented by the formula (I) in the preparation of a medicament for the prevention or treatment of diseases associated with PDE5 enzyme. The disease associated with PDE5 enzyme is erectile dysfunction, pulmonary hypertension, female sexual dysfunction, premature birth, dysmenorrhea, benign prostatic hyperplasia, bladder outlet obstruction, incontinence, unstable and variant angina, hypertension, congestive heart failure, renal failure, atherosclerosis, stroke, peripheral vascular disease, Raynaud's disease, inflammatory disease, bronchitis, chronic asthma, allergic asthma, allergic rhinitis, glaucoma or diseases characterized by enterocinesia disorders, etc."

ST. JUDE MEDICAL COORDINATION CENTER BVBA

Patent Issued for Sensor Guide Wire Comprising a Polymer Layer (USPTO 9526454)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- ST. JUDE MEDICAL COORDINATION CENTER BVBA (Zaventem, BE) has been issued patent number 9526454, according to news reporting originating out of Alexandria, Virginia, by NewsRx editors.

The patent's inventors are Mellin, Lisa (Uppsala, SE); Torne, Karin (Uppsala, SE). This patent was filed on March 13, 2013 and was published online on December 27, 2016.

From the background information supplied by the inventors, news correspondents obtained the following quote: "The present invention relates to a sensor guide wire, and in particular to a sensor guide wire provided with a polymer layer in the tip region.

"Today, there is an increased need for invasive measurements of physiological variables. For example, when investigating cardiovascular diseases, it is strongly desired to obtain local measurements of blood pressure, flow and temperature in order to evaluate the condition of the subject under measurement. Therefore, methods and devices have been developed for disposing a miniature sensor inside the body of an individual at a location where the measurements should be performed, and for communicating with the miniature sensor in order to provide the physician or medical technician with critical information as to the status of a patient's condition. Typically, the miniature sensor is arranged at a distal end of a guide wire, which is generally known in the art, and used for example in connection with the treatment of coronary disease.

"The distal end of the guide wire is inserted into the body of a patient, for example into an opening of the femoral artery, and placed at a desired location. Once the guide wire is placed by the physician into the appropriate location, e.g. in a coronary artery, the miniature sensor can measure the blood pressure and/or flow. The measurement of blood pressure is a way to diagnose e.g. the significance of a stenosis. For evident reasons, the dimensions of the sensor and the guide wire are fairly small; the guide wire typically has a diameter of 0.35 mm. Generally, the sensor element is in the form of an elongated, essentially rectangular chip with a pressure sensitive member in the form of a membrane provided thereon.

"In order to power the sensor and to communicate signals representing the measured physiological variable to a control unit acting as an interface device disposed outside the body, one or more microwires for transmitting the signals are connected to the sensor, and are routed along the guide wire to be passed out from the vessel to an external control unit via a connector assembly. Most commonly, extremely thin electrical cables are provided inside the guide wire, which itself is provided in the form of a tube (having an outer diameter of e.g. 0.35 mm), oftentimes made of stainless steel. In order to increase the bending strength and maneuverability of the tubular guide wire, a core wire is positioned inside the tube. The mentioned electrical leads are positioned in the space between the inner lumen wall of the tube and the core wire. Furthermore, the sensor chip is often arranged in a short tube, also referred to as a jacket or a sleeve. The jacket is hollow and accommodates, besides the sensor chip, a portion of a core wire and often at least one microwire. Furthermore, a first coil may be attached to the distal end of the jacket, and optionally a second coil may be attached to the proximal end of the jacket. The first and second coils may be attached to the respective end of the jacket, e.g. by gluing, or alternatively soldering. The purpose of the first coil is to provide a
tip with high flexibility. In addition, the distal coil is often designed to be radioopaque, to enable the user to locate the tip on an angiogram during use.

"A large flexibility of the sensor guide wire is advantageous in that it allows the sensor guide to be introduced into small and tortuous vessels. It should, however, also be recognized that if the core wire is too flexible, it would be difficult to push the sensor guide forward into the vessels, i.e. the sensor guide wire must possess a certain 'pushability' and a certain 'torquability.' Additionally, the sensor guide must be able to withstand the mechanical stress exerted on the core wire especially in sharp vessel bends.

"Several different designs of sensor guide wires are known in the prior art, and examples of such sensor guide wires are disclosed in U.S. Pat. No. 6,167,763 B1, which describes the cantilevered mounting of the sensor element, US RE39863 E1, which discloses the sensor element, and U.S. Pat. No. 6,248,083 B1, showing the complete sensor guide wire assembly, which all are assigned to the assignee of the present application, and which are hereby all incorporated by reference for the devices and methods described therein.

"A further example of a sensor guide wire is disclosed in WO 2009/054800 A1, assigned to the present assignee. The sensor guide wire has a proximal shaft region, a flexible region, a distal sensor region, and a tip region. The tip region of the sensor guide wire is provided with a tip core wire at least partly enclosed by a distal coil.

"Besides being flexible enough, it can be also important that the sensor guide wire tip responds when steering the sensor guide wire through the tortuous vessels, i.e. the sensor guide wire tip must also have sufficient 'steering response.' 'Steering response' is a measure of the irregular behavior of a sensor guide wire when the sensor guide wire tip is subjected to a non-linear pathway and rotated. This rotation is initiated by the user at the proximal end of the assembly, and depending on the characteristics of the different sections of the assembly, will be transferred along the wire in slightly different ways. The 'steering response' of a sensor guide wire tip is a general property of the distal tip components.

"The inventors of the present invention has further identified a need for a sensor guide wire with improved properties relating to the possibilities for the physician to feel constrictions and various bends and turns in the vessels when introducing the sensor guide wire. Thus, there is a need for a sensor guide wire which provides improved 'sensing capabilities.'"

Supplementing the background information on this patent, NewsRx reporters also obtained the inventors' summary information for this patent: "An object of the present invention is to achieve a sensor guide wire which is easier to introduce into small and tortuous vessels than prior art sensor guide wires.

"A further object of the present invention is to provide a sensor guide wire with improved 'sensing capabilities,' i.e. which facilitates for the physician to feel constrictions and plaque, and accordingly, facilitates maneuvering through the various bends and turns in the vessels.

"Still another object of the present invention is to provide a sensor guide wire which is easy to position correctly in the vessel.

"According to one aspect of the present invention, the above mentioned objects can be achieved by a sensor guide wire comprising a polymer layer in the tip region.

"According to a further aspect of the present invention, the above mentioned objects are achieved by a sensor guide wire comprising a polymer layer in the tip region which is radioopaque.

"In accordance with an embodiment of the present invention, the sensor guide wire, used for intravascular measurements of at least one physiological or other variable in a living
body, has a proximal region, a distal sensor region and a tip region.

"The sensor guide wire further comprises, a sensor element arranged in the sensor region, and comprising a sensor portion, for measuring the variable and to generate a sensor signal in response to the variable. A core wire, having a longitudinal axis A, and comprising at least a tip core wire portion, extends essentially along the tip region of the sensor guide wire.

"The tip core wire portion further comprises a distal tip, and at least a major part of the tip core wire portion is provided with a polymer layer essentially enclosing the at least major part.

"The sensor guide wire according to one embodiment of the present invention provides a smoother surface, which does not hinder advancement of the sensor guide wire in the tortuous vessels.

"An embodiment of the present invention may further provide a sensor guide wire which comprises a clearly visible radioopaque tip portion which facilitates the positioning of the sensor guide wire in the vessels.

"According to a further aspect of the present invention, the distal tip of the tip core wire portion of the sensor guide wire may be provided with an enlargement. The enlargement facilitates a secure attachment of the polymer layer and reduces the forces that the layer is subjected to. Furthermore, the enlargement improves the 'sensing capabilities.'

"It is to be understood that both the foregoing general description and the following detailed descriptions are exemplary and explanatory only, and are not restrictive of the invention as claimed."

MEDKARDIA LTD

Patent Issued for Stent Replacement System (USPTO 9526646)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- MEDKARDIA LTD. (Katsrin, IL) has been issued patent number 9526646, according to news reporting originating out of Alexandria, Virginia, by NewsRx editors.

The patent's inventors are Diamant, Valery (Katzrin, IL); Yasko, Nadezda (Tomsk, RU); Varshitsky, Boris (Jerusalem, IL); Borivker, Nachum (Jerusalem, IL); Lotan, Chaim (Jerusalem, IL).

This patent was filed on December 3, 2008 and was published online on December 27, 2016.

From the background information supplied by the inventors, news correspondents obtained the following quote: "Lesions in blood vessels can result from a build-up of an atherosclerotic plaque. The plaque build-up causes a narrowing of the vessel and reduced blood
flow therein. In the case of lesions in coronary arteries such reduced blood flow can lead to heart disease and death.

"Atherosclerotic lesions can also occur at or near an ostium--the opening of a branching conduit. Ostial lesions damage the ostium of a branching conduit. In aorto-ostial lesions, the treatment outcome using conventional balloon angioplasty has been limited by a low success rate and high incidence of restenosis, or recurrence of artery blockage. An attractive alternative for the treatment of this subset of lesions is coronary stenting.

"Coronary stent therapy of aorto-ostial lesions is limited by the need to precisely position the intravascular stent completely within the vascular lumen and as close as possible to the ostium. Limited visualization of the coronary artery ostium, angulations of the aorto-coronary segment and difficulties in the placement of the guiding catheter are all factors that affect the final result. If the stent is not placed far enough into the branch vessel, it extends into the aorta and thus may be subject to trauma from the guiding catheter. In this case, stent protrusion into the aortic lumen interferes with aortic blood flow and hastens further aortic catheterization. On the other hand, if the stent is placed too far into the branch vessel, it may miss the ostium and the tightest portion of the stenosis. In addition, there is the potential to compromise the lumen and subject the patient to a higher incidence of sub-acute stent thrombosis or restenosis, as well as a high risk for dissection, acute closure or rupture.

"Various stent placement systems for delivering stents to a vascular lumen immediately adjacent to an ostium are well known in the art. Such systems can utilize a balloon which is inflated around the catheter and used as a positioner against the ostial opening.

"For example, U.S. Pat. No. 5,749,890 describes a stent delivery assembly and method for stent placement in an ostial lesion. In particular, the stent delivery system of the invention comprises a break segment which changes configuration to facilitate localization of the target ostium.

"Balloon locators can function as a unitary body, however, since such balloons form a fairly rigid structure when inflated, angulation of an attached catheter with respect to an ostium while maintaining full contact between the balloon and the ostial opening, can be difficult if not impossible with such systems. Use of inflatable balloons is also limited by the need for complex inflation mechanisms.

"Locators are also known which include individual wire or polymer struts which are extended around the catheter and function as individual stops, each contacting a region of the ostial opening.

"For example, U.S. Pat. Appl. Publication No. 2004/181272A1 describes a stent combined with a positioning apparatus to effectively place the stent at a precise deployment site within a narrowed vascular region such as an artery. The stent is maneuvered through the vessel and is guided by a guiding catheter up the vessel to where the narrowing is located. Upon exiting the guiding catheter and approaching the deployment site within the coronary artery, a deployment site locator expands to contact the vascular structure and, thereby, effectively position the stent at the deployment site within the narrowed vessel.

"U.S. Pat. Appl. Publication No. 2007/156221A1 describes a stent positioning system, including an inflatable balloon for expanding a stent. The balloon, in its collapsed state, fits into and is adapted to carry the stent in its pre-expanded condition. Stent locator means are slidably accommodated in a guide catheter and adapted to change its shape prior to making contact with the interior wall surface of a major blood vessel in the ostial region of a smaller blood vessel branching off from the major vessel and prior to the expansion of the stent. Mechanical means for changing the shape of the stent locator means are also provided. The change of shape enables the locator means to abut the interior wall surface, thereby ensuring
correct apposition between the stent and the ostium of the smaller blood vessel.

"Locators in the form of independent and not interconnected loops are also known. For example, U.S. Pat. Appl. Publication No. 2007/173918A1 describes an apparatus and method for locating an ostium of a branch vessel. The apparatus includes a delivery catheter having a distal end sized for introduction into the branch, and locator elements including first ends fixed to the distal end and second ends free from the distal ends. The locator elements can be in the form of loops which are compressible from a transverse, deployed condition to an axial, contracted condition, wherein the second ends are disposed proximal to the first ends. During use, the catheter is directed through a guide catheter into the ostium with the locator elements compressed, and the locator elements are deployed within the branch in the contracted condition. The catheter is partially withdrawn from the branch, the locator elements resiliently expanding towards the deployed condition as they enter the main vessel. The catheter may be used to deliver a stent into the branch with the expanded locator elements facilitating positioning the stent.

"Locators with individual strut and loop attempt to overcome the limitations of balloon locators by providing independently movable struts and loops which are mechanically deployed and maintain independent contact with the tissue surrounding the ostium during catheter angulation. Although such configurations can in theory provide better catheter maneuverability, use of individual struts and loops can lead to strut mis-positioning and as a result escape of an individual strut(s) and/or loop(s) into the branch vessel."

Supplementing the background information on this patent, NewsRx reporters also obtained the inventors' summary information for this patent: "There is a need in the art to provide a stent delivery system that prevents both too distal and too proximal placement and implantation of the stent, i.e., a system that ensures proper stent-to-vessel positioning.

"It would also be advantageous to have a locator device which includes expandable locator elements that are elastically compliant while maintaining a single unitary structure.

"It would also be advantageous to have a locator device which includes expandable locator elements that forms a flexible, elastically compliant unitary structure when expanded.

"The present invention provides a comprehensive approach for accurate stent positioning. Generally, this approach provides a stent delivery system including one or more novel stent deployment site locators, attached to a guide catheter for a typical inflatable balloon outfitted stent.

"The present invention satisfies the aforementioned need by providing a novel system for delivering and placement of a stent or other medical prosthesis into or near an ostium of a vascular system or other tract system of an organism.

"As used herein, the phrase 'medical prosthesis' refers to any device which can be delivered into the body, specifically to a vessel such as a blood vessel. Examples of medical devices include, but are not limited to, stents, probes, angioplasty balloons and the like.

"The system comprises a delivery catheter having a proximal end, a distal end, and at least one lumen extending between the proximal and distal ends. The delivery catheter also includes an inflatable balloon mounted on the distal end of the delivery catheter for expanding and deploying the medical prosthesis placed on the balloon, and a stent deployment site locator configured for locating an exact place for positioning and facilitating the positioning of the medical prosthesis in or near an ostium.

"The deployment site locator comprises a plurality of filament elements that are interconnected between a locator proximal end and a locator distal end; thereby forming a unitary structure. The filament elements can be maintained in a compacted state within or on a catheter and expanded to form an interconnecting, interlocking or overlapping unitary structure.
The deployment site locator maintains a unitary and flexible structure (when expanded) and capable of being angled with respect to a longitudinal axis of a delivery catheter coupled to the locator.

"According to one embodiment of the present invention, the filament elements of the deployment site locator extend from a locator proximal end towards a locator distal end and then return after winding to the proximal end to form a plurality of filament loops. Contrary to the individual struts and loops of the prior art, the deployment site locator of the present invention includes interlocked or overlapping filament loops.

"The deployment site locator of the present invention can be integrated into a dedicated catheter system or configured as an add-on device which is attachable to standard or modified stent delivery catheter systems.

"According to one embodiment of the present invention, the filament elements of the deployment site locator extend from a locator proximal end towards a locator distal end and then return after winding to the proximal end to form a plurality of filament loops. Contrary to the individual struts and loops of the prior art, the deployment site locator of the present invention includes interlocked or overlapping filament loops.

"According to one embodiment of the present invention, the stent deployment site locator is mounted on the delivery catheter at the distal end before the inflatable balloon in relation to an operator using the system.

"According to another embodiment of the present invention, the stent deployment site locator is mounted on the delivery catheter at the distal end after the inflatable balloon in relation to an operator using the system.

"According to one embodiment of the present invention, the system for delivering and placement of a medical prosthesis comprises a carrier catheter configured for carrying the stent deployment site locator. The carrier catheter has a proximal end, a distal end, and an axially extending inner lumen provided within the carrier catheter to permit the stent delivery device to be inserted into the carrier catheter from the proximal end. The stent deployment site locator is mounted on the carrier catheter at the distal end.

"According to yet another embodiment of the present invention, the system for delivering and placement of a medical prosthesis comprises a clamp arranged on the carrier catheter for binding or pressing the carrier catheter and the delivery catheter together so as to hold them firmly and prevent their relative motion with respect to each other.

"According to still another embodiment of the present invention, the system for delivering and placement of a medical prosthesis comprises a guiding catheter including a lumen for housing the delivery catheter. The lumen has sufficient size for receiving the distal end of the delivery catheter therethrough together with the stent deployment site locator in a contracted condition.

"According to a further embodiment of the present invention, the system for delivering and placement of a medical prosthesis comprises a guiding catheter including a lumen for housing the carrier catheter. The lumen has sufficient size for receiving the distal end of the carrier catheter therethrough together with the stent deployment site locator in a contracted condition.

"According to one embodiment of the present invention, an outer diameter of the carrier catheter is less than an inner diameter of the guiding catheter to permit the carrier catheter to move within the guiding catheter.

"According to a further embodiment of the present invention, the system for delivering and placement of a medical prosthesis comprises a manipulator configured for manipulating the stent placement system for delivering and placing the medical prosthesis.

"According to one embodiment of the present invention, each filament of the plurality of filament elements originates from a certain point at the locator proximal end, and extends towards the locator distal end to form a loop and then returns to the same point at the locator proximal end.
"According to one embodiment of the present invention, the loops of the plurality of filament loops are not interconnected at said locator distal end.

"According to another embodiment of the present invention, a distal end of each loop is coupled to a distal end of the neighboring loops by means of a reinforcement wire to provide mechanical strengthening to the stent deployment site locator.

"According to still another embodiment of the present invention, each loop is overlapped and/or interlaced with at least one other neighboring loop.

"According to yet another embodiment of the present invention, the loops are directly bound to each other at overlapped points of the neighboring loops to provide mechanical strengthening to the stent deployment site locator.

"According to a further embodiment of the present invention, at least one wire is twisted around the loops at their distal ends.

"According to another embodiment of the present invention, each side of each loop is directly connected to a side of an adjacent loop at more than one point, thereby to provide structural rigidity and dilatation ability to said deployment site locator.

"According to another embodiment of the present invention, the connection of the sides of the loops along said proximal portion is achieved by twisting each pair of the filaments forming the corresponding sides.

"According to yet another embodiment of the present invention, the filaments of the plurality filament elements are made of metallic material having superelastic and thermomechanical shape memory characteristics. For example, the metallic material includes a radiopaque material.

"According to still another embodiment of the present invention, the filaments are made of non-metallic material.

"According to one embodiment of the present invention the system for delivering and placement of a medical prosthesis comprises a guide wire extending from a guide wire port at the proximal end of the stent delivery device through the lumen of the delivery catheter to an opening arranged in a tip of the distal end of the delivery catheter.

"For example, the guide wire port is arranged at the proximal end of the delivery catheter.

"According to another example, the guide wire port is arranged in a wall of the delivery catheter.

"According to yet another example, the guide wire port is arranged in a wall of the carrier catheter.

"According to still another example, the guide wire is fixed at the distal end of the delivery catheter.

"There has thus been outlined, rather broadly, the more important features of the invention in order that the detailed description thereof that follows hereinafter may be better understood. Additional details and advantages of the invention will be set forth in the detailed description, and in part will be appreciated from the description, or may be learned by practice of the invention."

Cardiac Pacemakers, Inc.

Patent Issued for System and Method for Evaluating a Patient Status for Use in Heart Failure Assessment (USPTO 9526456)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A patent by the inventor Bardy, Gust H. (Seattle, WA), filed on August 20, 2007, was published online on December 27, 2016, according to news reporting originating from Alexandria, Virginia, by NewsRx correspondents.

Patent number 9526456 is assigned to Cardiac Pacemakers, Inc. (St. Paul, MN).

The following quote was obtained by the news editors from the background information supplied by the inventors: "A broad class of medical subspecialties, including cardiology, endocrinology, hematology, neurology, gastroenterology, urology, ophthalmology, and otolaryngology, to name a few, rely on accurate and timely patient information for use in aiding health care providers in diagnosing and treating diseases and disorders. Often, proper medical diagnosis requires information on physiological events of short duration and sudden onset, yet these types of events are often occur infrequently and with little or no warning. Fortunately, such patient information can be obtained via external, implantable, cutaneous, subcutaneous, and manual medical devices, and combinations thereof. For example, in the area of cardiology, implantable pulse generators (IPGs) are commonly used to treat irregular heartbeats, known as arrhythmias. There are three basic types of IPGs. Cardiac pacemakers are used to manage bradycardia, an abnormally slow or irregular heartbeat. Bradycardia can cause symptoms such as fatigue, dizziness, and fainting. Implantable cardioverter defibrillators (ICDs) are used to treat tachycardia, heart rhythms that are abnormally fast and life threatening. Tachycardia can result in sudden cardiac death (SCD). Finally, implantable cardiovascular monitors and therapeutic devices are used to monitor and treat structural problems of the heart, such as congestive heart failure and rhythm problems.

"Pacemakers and ICDs, as well as other types of implantable and external medical devices, are equipped with an on-board, volatile memory in which telemetered signals can be stored for later retrieval and analysis. In addition, a growing class of cardiac medical devices, including implantable heart failure monitors, implantable event monitors, cardiovascular monitors, and therapy devices, are being used to provide similar stored device information. These devices are able to store more than thirty minutes of per heartbeat data. Typically, the telemetered signals can provide patient device information recorded on a per heartbeat, binned average basis, or derived basis from, for example, atrial electrical activity, ventricular electrical activity, minute ventilation, patient activity score, cardiac output score, mixed venous oxygen score, cardiovascular pressure measures, time of day, and any interventions and the relative success of such interventions. In addition, many such devices can have multiple sensors, or several devices can work together, for monitoring different sites within a patient's body.

"Presently, stored device information is retrieved using a proprietary interrogator or programmer, often during a clinic visit or following a device event. The volume of data
retrieved from a single device interrogation 'snapshot' can be large and proper interpretation and analysis can require significant physician time and detailed subspecialty knowledge, particularly by cardiologists and cardiac electrophysiologists. The sequential logging and analysis of regularly scheduled interrogations can create an opportunity for recognizing subtle and incremental changes in patient condition otherwise undetectable by inspection of a single 'snapshot.' However, present approaches to data interpretation and understanding and practical limitations on time and physician availability make such analysis impracticable.

"A prior art system for collecting and analyzing pacemaker and ICD telemetered signals in a clinical or office setting is the Model 9790 Programmer, manufactured by Medtronic, Inc., Minneapolis, Minn. This programmer can be used to retrieve data, such as patient electrocardiogram and any measured physiological conditions, collected by the IPG for recordation, display and printing. The retrieved data is displayed in chronological order and analyzed by a physician. Comparable prior art systems are available from other IPG manufacturers, such as the Model 2901 Programmer Recorder Monitor, manufactured by Guidant Corporation, Indianapolis, Ind., which includes a removable floppy diskette mechanism for patient data storage. These prior art systems lack remote communications facilities and must be operated with the patient present. These systems present a limited analysis of the collected data based on a single device interrogation and lack the capability to recognize trends in the data spanning multiple episodes over time or relative to a disease specific peer group.

"A prior art system for locating and communicating with a remote medical device implanted in an ambulatory patient is disclosed in U.S. Pat. No. 5,752,976 ('976). The implanted device includes a telemetry transceiver for communicating data and operating instructions between the implanted device and an external patient communications device. The communications device includes a communication link to a remote medical support network, a global positioning satellite receiver, and a patient activated link for permitting patient initiated communication with the medical support network.

"Related prior art systems for remotely communicating with and receiving telemetered signals from a medical device are disclosed in U.S. Pat. Nos. 5,113,869 ('869) and 5,336,245 ('245). In the '869 patent, an implanted AECG monitor can be automatically interrogated at preset times of day to telemeter out accumulated data to a telephonic communicator or a full disclosure recorder. The communicator can be automatically triggered to establish a telephonic communication link and transmit the accumulated data to an office or clinic through a modem. In the '245 patent, telemetered data is downloaded to a larger capacity, external data recorder and is forwarded to a clinic using an auto-dialer and fax modem operating in a personal computer-based programmer/interrogator. However, the '976 telemetry transceiver, '869 communicator, and '245 programmer/interrogator are limited to facilitating communication and transferal of downloaded patient data and do not include an ability to automatically track, recognize, and analyze trends in the data itself.

"In addition, the uses of multiple sensors situated within a patient's body at multiple sites are disclosed in U.S. Pat. No. 5,040,536 ('536) and U.S. Pat. No. 5,987,352 ('352). In the '536 patent, an intravascular pressure posture detector includes at least two pressure sensors implanted in different places in the cardiovascular system, such that differences in pressure with changes in posture are differentially measurable. However, the physiological measurements are used locally within the device, or in conjunction with any implantable device, to effect a therapeutic treatment. In the '352 patent, an event monitor can include additional sensors for monitoring and recording physiological signals during arrhythmia and syncopal events. The recorded signals can be used for diagnosis, research or therapeutic study, although no systematic approach to analyzing these signals, particularly with respect to peer and general population groups, is presented.
"Thus, there is a need for a system and method for providing continuous retrieval, transferal, and automated analysis of retrieved medical device information, such as telemetered signals, retrieved in general from a broad class of implantable and external medical devices. Preferably, the automated analysis would include recognizing a trend indicating disease absence, onset, progression, regression, and status quo and determining whether medical intervention is necessary.

"There is a further need for a system and method that would allow consideration of sets of collected measures, both actual and derived, from multiple device interrogations. These collected measures sets could then be compared and analyzed against short and long term periods of observation.

"There is a further need for a system and method that would enable the measures sets for an individual patient to be self-referenced and cross-referenced to similar or dissimilar patients and to the general patient population. Preferably, the historical collected measures sets of an individual patient could be compared and analyzed against those of other patients in general or of a disease specific peer group in particular."

In addition to the background information obtained for this patent, NewsRx journalists also obtained the inventor's summary information for this patent: "The present invention provides a system and method for automated collection and analysis of patient information retrieved from an implantable medical device for remote patient care. The patient device information relates to individual measures recorded by and retrieved from implantable medical devices, such as IPGs and monitors. The patient device information is received on a regular, e.g., daily, basis as sets of collected measures, which are stored along with other patient records in a database. The information can be analyzed in an automated fashion and feedback provided to the patient at any time and in any location.

"An embodiment provides a system and method for evaluating a patient status for use in heart failure assessment. Physiological measures, which were directly recorded as data on a substantially continuous basis by a medical device for a patient or indirectly derived from the data are assembled. A status is determined for the patient through sampling and analysis of the physiological measures over a plurality of data assembly points. The physiological measures relative to the patient status are evaluated by analyzing any trend, including one of a status quo and a change in cardiac performance and comparing the trend to cardiac decompensation indications.

"A further embodiment provides a system and method for evaluating a patient status from sampled physiometry for use in heart failure assessment. Physiological measures, including at least one of direct measures regularly recorded on a substantially continuous basis by a medical device for a patient and measures derived from the direct measures are stored. At least one of those of the physiological measures, which each relate to a same type of physiometry, and those of the physiological measures, which each relate to a different type of physiometry are sampled. A status is determined for the patient through analysis of those sampled physiological measures assembled from a plurality of recordation points. The sampled physiological measures are evaluated. Trends that are indicated by the patient status, including one of a status quo and a change, which might affect cardiac performance of the patient, are identified. Each trend is compared to cardiac decompensation indications to generate a notification of parameter violations.

"Still other embodiments of the present invention will become readily apparent to those skilled in the art from the following detailed description, wherein is described embodiments of the invention by way of illustrating the best mode contemplated for carrying out the invention. As will be realized, the invention is capable of other and different embodiments"
and its several details are capable of modifications in various obvious respects, all without departing from the spirit and the scope of the present invention. Accordingly, the drawings and detailed description are to be regarded as illustrative in nature and not as restrictive."

Medtentia International Ltd. Oy

Patent Issued for System for Improving the Function of a Heart Valve (USPTO 9526614)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- According to news reporting originating from Alexandria, Virginia, by NewsRx journalists, a patent by the inventor Keranen, Olli (Bjarred, SE), filed on August 4, 2010, was published online on December 27, 2016.

The assignee for this patent, patent number 9526614, is Medtentia International Ltd. Oy (Helsinki, FI).

Reporters obtained the following quote from the background information supplied by the inventors: "Diseased mitral and tricuspid valves frequently need replacement or repair. The mitral and tricuspid valve leaflets or supporting chordae may degenerate and weaken or the annulus may dilate leading to valve leak (insufficiency). The leaflets and chords may become calcified and thickened rendering them stenotic (obstructing forward flow). Finally, the valve relies on insertion of the chordae inside the ventricle. If the ventricle changes in shape, the valve support may become non-functional and the valve may leak.

"Mitral and tricuspid valve replacement and repair are traditionally performed with a suture technique. During valve replacement, sutures are spaced around the annulus (the point where the valve leaflet attaches to the heart) and then the sutures are attached to a prosthetic valve. The valve is lowered into position and when the sutures are tied, the valve is fastened to the annulus. The surgeon may remove all or part of the valve leaflets before inserting the prosthetic valve. In valve repair, a diseased valve is left in situ and surgical procedures are performed to restore its function. Frequently an annuloplasty ring is used to reduce the size of the annulus. The ring serves to reduce the diameter of the annulus and allow the leaflets to oppose each other normally. Sutures are used to attach a prosthetic ring to the annulus and to assist in plicating the annulus.

"In general, the annuloplasty rings and replacement valves must be sutured to the valve annulus and this is time consuming and tedious. If the ring is severely malpositioned, then the stitches must be removed and the ring repositioned relative to the valve annulus during restitching. In other cases, a less than optimum annuloplasty may be tolerated by the surgeon
rather than lengthening the time of the surgery to restitch the ring.

"During heart surgery, a premium is placed on reducing the amount of time used to replace and repair valves as the heart is frequently arrested and without perfusion. It would therefore be very useful to have a method to efficiently attach a prosthesis into the mitral or tricuspid valve position.

"In U.S. Pat. No. 6,419,696, an annuloplasty device is disclosed. The annuloplasty device comprises a first and a second support ring, which are connected to each other to form a coiled configuration. The first and second support rings are arranged to abut opposite sides of a valve annulus to trap valve tissue therebetween. This annuloplasty device may be easily applied to the valve by rotating the device into position on opposite sides of the valve annulus."

In addition to obtaining background information on this patent, NewsRx editors also obtained the inventor's summary information for this patent: "It is an object of the invention to provide an improved valve repair. It is a specific object of the invention to provide an annuloplasty device, which provides a lessened risk for rupture of valve leaflets when applied to the heart valve.

"These and other objects of the invention are accomplished by means of devices according to the independent claims. Preferred embodiments of the invention are apparent from the dependent claims.

"According to a first aspect of the invention, there is provided a device for improving the function of a heart valve comprised of valve tissue including an annulus and a plurality of leaflets. The device comprises a first loop-shaped support, which is configured to abut a first side of the heart valve, and a second loop-shaped support, which is configured to abut a second side of the heart valve opposite to said first side, whereby a portion of the valve tissue is trapped between the first and second supports, wherein an outer boundary of the second support is greater than an outer boundary of the first support.

"This device may be used to perform annuloplasty, that is to reshape the valve annulus, in order to improve the function of the valve. The first and second loop-shaped supports are to be positioned on opposite sides of the heart valve and trap valve tissue therebetween to fixate a desired shape of the valve. The device may also be used to carry and position a replacement heart valve.

"The feature that the outer boundary of the second support is greater than the outer boundary of the first support implies that the device, when properly positioned at a heart valve, may be arranged such that the first and second loop-shaped supports are displaced to one another on the opposite sides of the heart valve. It has been found that this arrangement diminishes a risk that a rupture is created in the leaflets, which during normal heart action bends over the lower support to open the valve. A possible explanation for this diminished rupture risk is that since the supports are displaced to one another, the pinch between the first and second supports does not sharply define a radial position in which the leaflets of the valve bend over the lower support. When using the device on an atrial valve, the lower support may now be arranged close to the annulus of the valve, which is larger on its ventricular side. Thereby, the device may also be arranged to minimally affect the movement of the leaflets during normal heart action. Further, a large lower support provides a possibility to move the support around the chords in the left ventricle during insertion of the device. However, it is conceivable that the diminished rupture risk may be achieved by instead making the outer boundary of the upper support greater than the outer boundary of the lower support.

"As used herein, the term 'loop-shaped' should be construed as a curved shape that may be closed as a ring with a circular, elliptic, or D-shaped form or any other closed form which may fit the shape of the valve annulus. The term 'loop-shaped' also includes a curved
shape that is open forming an arcuate shape, such as a C-shape or U-shape, which includes an angular turn of at least 180 degree. such that the support may abut valve tissue along a major part of the annular valve shape. The term 'loop-shaped' also includes a curved shape overlapping itself to form a portion of a coil.

"The first and the second loop-shaped supports may be separate entities and may be arranged to be connected when inserted in engagement with valve tissue.

"Alternatively, an end of the first loop-shaped support may be connected to an end of the second loop-shaped support through a connecting part, whereby the supports and the connecting part form a coil-shape.

"This implies that the first and second supports may be simultaneously applied in position at the heart valve. When used for an atrial valve, the coil-shape may be applied from the atrial side at a commissure between the leaflets of the atrial valve and be rotated 360 degree. such that one loop-shaped support is inserted through the commissure to extend along the valve on its ventricular side and the other loop-shaped support is arranged along the valve on its atrial side.

"The connecting part may be releasably attached to the first and second loop-shaped supports for disconnecting the end of the first loop-shaped support from the end of the second loop-shaped support after insertion to the heart valve.

"This implies that the device may be placed in abutment with the heart valve without having any part extending through the opening of the heart valve. Thus, the first and second supports may separately be arranged in abutment with valve tissue such that each support may over time grow into the valve tissue. As a result, the device does not present any surface of foreign material that may cause blood clot forming or tissue overgrowth in the opening of the heart valve.

"The first loop-shaped support may be continuous with the second loop-shaped support to form a coil-shaped member. This implies that the device has a simple design comprising a single coil-shaped part, which may easily be positioned in a heart valve by rotating the coil-shaped member such that the loop-shaped supports are arranged on opposite sides of the valve.

"An end portion of the coil-shaped member may be bent such that the end portion has a greater pitch than the rest of the coil-shaped member. This is especially advantageous when using the device to treat an atrial valve. When rotating the coil-shaped member for positioning the device, a greater pitch of the leading end of the coil-shaped member entering the ventricle implies that a risk that the coil-shaped member gets stuck in the chords during insertion is reduced.

"The second support may have a round cross-section. The first support may also have a round cross-section. This implies that a rounded edge is presented to the valve tissue being trapped, whereby a risk that a rupture is created in the leaflets is further diminished.

"The first and second supports may have equal shapes, wherein the second support is in larger scale than the first support. This implies that the relationship between the first and second support is equal over the entire valve. As a result, the pinch between the first and second supports is constant over the entire valve.

"The outer boundary of the first support may be larger than an inner boundary of the second support. This implies that the supports overlap somewhat, whereby the pinch between the supports certainly is sufficiently strong to maintain a remodelled shape of the heart valve.

"Preferably, the outer boundary of the first support corresponds to a curve through the center of the second support.
"The first and second supports are preferably D-shaped. Such shape would conform to the shape of the atrial valve annulus and is therefore especially useful for treatment of atrial valves.

"The first and second supports may each have an inner core covered by an outer layer, said inner core being formed from a more rigid material than said outer layer. The inner core may be formed from a metallic material, whereas the outer core may be formed from a fabric material. This implies that the surface of the support in contact with the valve tissue is soft to diminish the risk of rupture of the leaflets, whereas the support has a rigid shape which is maintained to retain a changed shape of the valve.

"Alternatively, the first and second supports may be formed from a shape memory material. This implies that the supports may assume a desired, predetermined shape when inserted into position and maintain this shape.

"The device may further comprise a plurality of fasteners arranged to extend between said first and second supports when the supports are placed on opposite sides of the heart valve. The fasteners would then serve to fix the position of the supports to each other and to the valve.

"The first and second supports may comprise bores for receiving said fasteners therethrough. Thus, the positioning of the fasteners in the supports is predetermined for accomplishing a secure fixation.

"The device may further comprise a removable material on at least one of said first and second supports for reducing friction between the respective supports and the valve tissue during initial engagement therewith, said material being removable to increase the friction during securement of the device to the valve tissue. The removable material provides a reduced friction which facilitates the guiding of the supports into abutment with the valve tissue and, when properly positioned, removing the removable material provides an increased friction that will serve to retain the relative position of the support and the valve tissue.

"The opposed surfaces of the first and second supports may be roughened to facilitate engagement with the valve tissue. The opposed surfaces may be roughened in a pattern extending along the longitudinal direction of the rings. This implies that the roughened surface will serve to prevent slippage of tissue through the pinch of the supports while presenting a low friction for the supports to be turned into position abutting the valve.

"According to a second aspect of the invention, there is provided a kit for improving the function of a heart valve comprised of valve tissue including an annulus and a plurality of leaflets. The kit comprises a first loop-shaped support, which is configured to abut a first side of the heart valve, a second loop-shaped support, which is configured to abut a second side of the heart valve opposite to said first side, whereby a portion of the valve tissue is trapped between the first and second supports. The kit further comprises at least one fastener for connecting the first and second supports when arranged in engagement with the heart valve.

"The kit may be used to perform annuloplasty, that is to reshape the valve annulus, in order to improve the function of the valve. The kit comprises first and second loop-shaped supports, which are to be positioned on opposite sides of the heart valve, and fasteners, which connect the supports and fixate them to each other and to the valve tissue. As a result, valve tissue will be trapped between the supports to fixate a desired shape of the valve. The first and second supports are separate entities which may be separately placed on opposite sides of the heart valve. This implies that while the first and second supports may over time grow into the valve tissue, the kit does not present any surface of foreign material that may cause blood clot forming or tissue overgrowth in the opening of the heart valve.

"The first and second supports may comprise receiving members for receiving said at least one fastener. The location of the receiving members at the first and second supports will
then determine the relationship between the first and second supports that will be fixated by the fasteners.

"The at least one fastener may be arranged on the first support and the second support may comprise receiving members for receiving said at least one fastener. As a result, the kit consists of fewer parts and the fasteners may be introduced into a patient together with the first support.

"The at least one fastener may comprise a sharp projection for penetrating valve tissue. This facilitates positioning of the fastener in the patient, since a relatively small force is needed for pushing the fastener through the valve tissue.

"The supports may be formed from a magnetic material such that the supports when being introduced on opposite sides of the heart valve may be subject to a magnetic field to attract the supports towards each other for temporarily fixating them on the opposite sides of the heart valve. In this way, the interrelationship of the supports may be at least temporarily fixated without the need of fasteners penetrating valve tissue. Thus, the positions of the supports may be temporarily fixated while the positions are secured by fasteners.

"According to a third aspect of the invention, there is provided a device for improving the function of a heart valve comprised of valve tissue including an annulus and a plurality of leaflets. The device comprises a first loop-shaped support, which is configured to abut a first side of the heart valve, a second loop-shaped support, which is configured to abut a second side of the heart valve opposite to said first side, whereby a portion of the valve tissue is trapped between the first and second supports, and a connecting part for connecting an end of the first loop-shaped support to an end of the second loop-shaped support such that the supports and the connecting part form a coil-shape.

"The device may be used to perform annuloplasty, that is to reshape the valve annulus, in order to improve the function of the valve. The device comprises first and second loop-shaped supports, which are to be positioned on opposite sides of the heart valve, and a connecting part, which connect the supports such that a coil-shape is formed. As a result, the coil-shape may be applied at a commissure between the leaflets of the heart valve and be rotated 360.degree. such that one loop-shaped support is inserted through the commissure to extend along one side of the valve and the other loop-shaped support is arranged along the opposite side of the valve. Thus, valve tissue will be trapped between the supports to fixate a desired shape of the valve.

"The connecting part may be releasably attached to at least one of the first and second loop-shaped supports for disconnecting the end of the first loop-shaped support from the end of the second loop-shaped support after insertion to the heart valve.

"This implies that the device may be placed in abutment with the heart valve without having any part extending through the opening of the heart valve. Thus, the first and second supports may separately be arranged in abutment with valve tissue such that the each support may over time grow into the valve tissue. As a result, the device does not present any surface of foreign material that may cause blood clot forming or tissue overgrowth in the opening of the heart valve.

"The device may further comprise a carrier removably coupled to the supports for carrying the supports to the heart valve, wherein the connecting part is attached to the carrier such that the connecting part may be removed with the carrier after the supports have been placed in engagement with valve tissue. As a result, the supports may be easily applied at the heart valve by rotating the coil-shaped member. After the insertion of the supports, the connecting part may be removed such that the implanted device does not present any surface of foreign material that may cause blood clot forming or tissue overgrowth in the opening of the

Lubrizol Advanced Materials, Inc.

Patent Issued for Telechelic N-Alkylated Polyamide Polymers and Copolymers (USPTO 9527961)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- From Alexandria, Virginia, NewsRx journalists report that a patent by the inventors Erdodi, Gabor (Cleveland, OH); Pourahmady, Naser (Solon, OH); Lai, John Ta-Yuan (Broadview Heights, OH), filed on February 3, 2014, was published online on December 27, 2016.

The patent's assignee for patent number 9527961 is Lubrizol Advanced Materials, Inc. (Cleveland, OH).

News editors obtained the following quote from the background information supplied by the inventors: "Vol. 38 (October 1946) of Industrial and Engineering Chemistry, pp. 1016-1019 titled Melting Points of N-Substituted Polyamides, by authors B. S. Biggs, C. J. Frosch, and R. H. Erickson studies the effect substitution on a nitrogen of a polyamide and the correlation of the polyamide melting points with the degree and type of substitution.

"U.S. Pat. No. 4,992,500 describes Aqueous Dispersions of Polyamides Emulsified with Rosin Derivatives.

Elastomers with Hydrolytic and Thermoxidative Stability. II. Polyurethanes with N-Alkylated Polyamide Soft Blocks discloses copolymides where the alkyl group on the amine is methyl, ethyl, isopropyl, or butyl and the diacid is a carbonate.

"U.S. Pat. No. 5,610,224 discloses an ionic and nonionic polyamide modified polyurethane polymers for use in coating compositions, method for forming, and coating compositions containing these polymers.

"EP 594 292 A1 describes N-alkylated aminoalcohols reacted with a lactone. That reaction product is reacted with a diester of a dicarboxylic acid or an anhydride of a dicarboxylic acid.

"U.S. Pat. No. 7,276,570 titled Compositions for Golf Equipment and assigned to Acushnet Company discloses golf balls comprising thermoplastic, thermoset, castable, or millable elastomer compositions comprising at least one polymer having a plurality of anionic moieties attached thereto. The compositions can be used as part of golf ball construction.

"WO2006/053777 A1 to Novartis Pharma Gmbh discloses crosslinkable poly (oxygenalkylene) containing polyamide prepolymers that can be used to provide water-soluble prepolymer that can be used as a component in contact lenses.

"US 2008/0090956 A1 discloses water-dilutable, hydroxy-functional polyurethanes containing amide structural units, a process for preparing them, and aqueous coating compositions prepared from them.

"EP 449419 A1 describes reacting primary aminoalcohols with acid terminated polyamideethers to create hydroxyl terminated polymers."

As a supplement to the background information on this patent, NewsRx correspondents also obtained the inventors' summary information for this patent: "This invention relates to low molecular weight polyamide oligomers and telechelic polyamides (including copolymers) comprising N-alkylated amide groups in the backbone structure. These polymers are useful as soft segments in the preparation of thermoplastic, thermoset, or elastomer resins and water-borne dispersions of those resins. The unique feature of these polyamide polymers is their ability to be processed as liquids at temperatures from 20 to 50 or 80 degree C., which makes them suitable for further reaction and polymerization forming various thermoplastic or thermoplastic elastomer compositions."

Patent Issued for Transcatheter Valve Replacement (USPTO 9526612)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- From Alexandria, Virginia, NewsRx journalists report that a patent by the inventors Board, Stephanie Marie (West St. Paul, MN); Chalekian, Aaron J. (Savage, MN); Russo, Patrick P. (Vadnais Heights, MN); Oslund, John (Blaine, MN), filed on July 27, 2015, was published online on December 27, 2016.

The patent's assignee for patent number 9526612 is St. Jude Medical Cardiology Division, Inc. (St. Paul, MN).

News editors obtained the following quote from the background information supplied by the inventors: "The present disclosure relates to heart valve replacement and, in particular, to collapsible prosthetic heart valves. More particularly, the present disclosure relates to devices and methods for anchoring collapsible prosthetic heart valves within the native valve annulus.

"Prosthetic heart valves that are collapsible to a relatively small circumferential size can be delivered into a patient less invasively than valves that are not collapsible. For example, a collapsible valve may be delivered into a patient via a tube-like delivery apparatus such as a catheter, a trocar, a laparoscopic instrument, or the like. This collapsibility can avoid the need for a more invasive procedure such as full open-chest, open-heart surgery.

"Collapsible prosthetic heart valves typically take the form of a valve structure mounted on a stent. There are two types of stents on which the valve structures are ordinarily mounted: a self-expanding stent and a balloon-expandable stent. To place such valves into a delivery apparatus and ultimately into a patient, the valve must first be collapsed or crimped to reduce its circumferential size.

"When a collapsed prosthetic valve has reached the desired implant site in the patient (e.g., at or near the annulus of the patient's heart valve that is to be replaced by the prosthetic valve), the prosthetic valve can be deployed or released from the delivery apparatus and re-expanded to full operating size. For balloon-expandable valves, this generally involves releasing the entire valve, assuring its proper location, and then expanding a balloon positioned within the valve stent. For self-expanding valves, on the other hand, the stent automatically expands as the sheath covering the valve is withdrawn."

As a supplement to the background information on this patent, NewsRx correspondents also obtained the inventors' summary information for this patent: "In some embodiments, a prosthetic heart valve having an inflow end and an outflow end may include a collapsible and expandable stent and a collapsible and expandable valve assembly disposed within the stent and having a plurality of leaflets. The prosthetic heart valve may further include a collapsible and expandable frame formed of braided wires, the frame having a body portion and a lumen extending through the body portion for receiving the stent and the valve assembly.

"In some embodiments, a method of deploying a prosthetic heart valve at a target site is described. The prosthetic heart valve includes a collapsible and expandable stent, a collapsible and expandable valve assembly disposed within the stent, and a collapsible and expandable frame formed of braided wires, the frame having a body portion and a lumen extending through the body portion for receiving the stent and the valve assembly. The method includes deploying the prosthetic heart valve via a delivery device at the target site in a collapsed configuration and allowing the prosthetic heart valve to re-expand at the target site, the prosthetic heart valve being coupled to the delivery device, repositioning the prosthetic heart valve.
valve at the target site using the delivery device and decoupling the prosthetic heart valve from the delivery device after evaluating functionality of the prosthetic heart valve."

The UAB Research Foundation

**Patent Issued for Treating Basal-Like Genotype Cancers (USPTO 9527915)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- A patent by the inventors Buchsbaum, Donald J. (Alabaster, AL); Zhou, Tong (Birmingham, AL); LoBuglio, Albert F. (Birmingham, AL), filed on November 5, 2010, was published online on December 27, 2016, according to news reporting originating from Alexandria, Virginia, by NewsRx correspondents.

Patent number 9527915 is assigned to The UAB Research Foundation (Birmingham, AL).

The following quote was obtained by the news editors from the background information supplied by the inventors: "Triple negative breast cancer (TNBC) represents a significant proportion (about 20-25%) of breast cancer patients. TNBC is characterized by the absence of HER2, estrogen receptor (ER), and progesterone receptor (PR). TNBC has a poor prognosis, and no targeted approach to a therapy has been found to date."

In addition to the background information obtained for this patent, NewsRx journalists also obtained the inventors' summary information for this patent: "Provided are methods of treating a subject with cancer. The methods comprise selecting a subject with a breast cancer, wherein the breast cancer is a basal-like genotype cancer and wherein the breast cancer is HER2 non-amplified, and administering to the subject a death receptor agonist."

"Optionally, the methods comprise selecting a subject with a breast cancer, wherein the breast cancer has one or more characteristics selected from the group consisting of a luminal cell, HER2 amplified, or basal-like genotype; administering to the subject an IAP inhibitor; and administering to the subject a death receptor agonist.

"Also provided are methods of screening a breast cancer cell for responsiveness to a DR5 agonist. The methods comprise detecting a basal-like phenotype in the cancer cell; detecting the cancer cell is HER2 non-amplified; and detecting a reduced level of a DR5/DDX3/cIAP1 complex in the cancer cell as compared to a control.

"Also provided are methods of screening a triple negative breast cancer cell for responsiveness to a DR5 agonist. Optionally, the methods comprise detecting a level of a DR5/DDX3/cIAP1 complex in the cell and comparing it to a control. A lower level of complex in the cell as compared to the control indicates responsiveness.
"Optionally, the methods comprise detecting in the breast cancer cell a DDX3 lacking an N-terminal caspase-associated recruitment domain (CARD). The DDX3 lacking the N-terminal CARD indicates the breast cancer cell is responsive to a DR5 agonist.

"Optionally, the methods comprise detecting in the breast cancer cell IAP proteins including an 80 kDa baculovirus IAP repeat. The 80 kDa baculovirus IAP repeat indicates the breast cancer cell is not responsive to a DR5 agonist.

"Further provided are antibodies that selectively bind an N-terminal CARD of DDX3. Also provided are antibodies that selectively bind a DDX3 lacking an N-terminal CARD. Also provided are antibodies that selectively bind IAP proteins including an 80 kDa baculovirus IAP repeat (BIR)."

Keywords for this news article include: Antibodies, Oncology, Immunology, Breast Cancer, Blood Proteins, Women's Health, Immunoglobulins, Diagnostics and Screening, The UAB Research Foundation.

KUNMING SHENGHUO PHARMACEUTICAL
Patent Issued for Use of Dencichine in Preparation of Drug for Treating Thrombocytopenia (USPTO 9526713)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- KUNMING SHENGHUO PHARMACEUTICAL (GROUP) CO., LTD. (Kunming, Yunnan, CN) has been issued patent number 9526713, according to news reporting originating out of Alexandria, Virginia, by NewsRx editors.

The patent's inventors are Lan, Guihua (Kunming, CN); Lan, Feng (Kunming, CN); Sun, Xiaobo (Kunming, CN).

This patent was filed on May 24, 2013 and was published online on December 27, 2016.

From the background information supplied by the inventors, news correspondents obtained the following quote: "Platelets are the smallest blood cells with primary function of coagulation and hemostasis. When a body gets injured to bleed, platelets will gather at the site of injury in droves within several seconds. Firstly the platelets release vasoconstrictive substance for constricting the damaged blood vessel in varying degrees, then the platelets and other blood-clotting substance in the blood adhere to the damaged vessel wall and clump together to form a clot and accordingly block the damaged wounds and blood vessels. The platelet count of a healthy person is 100.times.10.sup.9/L.about.300.times.10.sup.9/L and the platelet's average life is 8.about.12 days. Thrombopenias means that the platelet count results are below a lower limit of reference value due to various reasons.

"Thrombopenias may cause the following harmfulness: 1. causing mucosal bleeding (such as nasal mucosa bleeding, oral mucosal bleeding, gastrointestinal mucosal bleeding,
genitourinary tract bleeding, vaginal bleeding, etc.); 2. postoperative massive hemorrhage; 3. multiple petechiae and purpura occurred most frequently in the legs; 4. causing gastrointestinal massive hemorrhage and central nervous system internal hemorrhage that may threaten life.

"Thrombopenia is caused by a great many reasons, such as decrease in platelets generation, excess destruction of platelets, excess retention of platelets within the spleen, etc. (1) Decrease of platelets generation is caused by destruction of hematopoietic stem cells or affection of their proliferation in the bone marrow cells due to some factors such as drugs, cancer, infection, ionizing radiation, etc. (2) Excess destruction of platelets may commonly be found in idiopathic thrombocytic purpura and consumptive thrombocytopenia, such as disseminated intravascular coagulation, thrombotic thrombocytic purpura. (3) Excess retention of platelets within the spleen may commonly be found in hypersplenism. The above factors often coexist on one body. In clinical, except that pseudo-thrombocytopenia doesn't need treating, both drug-induced thrombocytopenia and pathological thrombocytopenia need treating by treatment means.

"Drug-induced thrombocytopenia (DITP) is a hemorrhagic disease resulting from the decrease of platelet count in the blood due to some drugs, and manifests that the drug-induced platelet count is lower than 100.times.10.sup.9/L and the platelet count of severe thrombocytopenia is lower than 5.times.10.sup.9/L. DITP is often caused by the following drugs: anti-clotting drugs such as heparin, antineoplastic drugs and immunosuppressant, antibacterial drugs such as chloramphenicol and sulfonamides, antipyretic analgesics such as aspirin and acetaminophen, diuretics such as chlorothiazide, antiepileptic drugs such as phenytoin and carbamazepine, hypoglycemic drugs such as chlorpropamide and tolbutamide, oestrogenic substance such as diethylstilbestrol, some vaccines, some Chinese medicine preparations, some lipid-lowering drugs, cimetidine, bismuth, digitoxin, organic arsenics, and other drugs.

"The pathological thrombocytopenia mainly includes primary and secondary thrombocytic purpura, aplastic anemia, acute leukemia, megaloblastic anemia. DIC, hypersplenism, radiation syndrome, kala azar, typhoid fever, tuberculosis, bone metastases, and progressive extracorporeal circulation and the like. The most common in clinical is thrombocytic purpura.

"For many years, many scholars at home and abroad conduct in-depth research on the treatment of Thrombocytopenia, and have achieved some achievements. There are a plurality of methods for treating Thrombocytopenia, comprising first-line treatment: administration of glucocorticosteroid, intravenous immunoglobulin and splenectomy; second-line treatment: intravenous anti-Rh(D) immunoglobulin and immunosuppressant. The treatment methods, such as platelet transfusion, plasma exchange, protein immunoabsorption, can be used if the above first and second line treatments have failed. Wherein, the platelet transfusion is an effective method to treat Thrombocytopenia, but its clinical application is limited because of short preservation time, lack of blood supply, high cost, possible blood-borne infections, transfusion reaction and producing platelet antibodies. In addition, repetition of platelet transfusions may, cause platelet transfusion refractoriness, therefore threatening the patient's life all the time. Although interleukin-11 (IL-11) and thrombopoietin (TPO) have preferable curative effect for treating Thrombocytopenia, they are unable to be widely applied in clinic due to great adverse reactions and expensive price. Therefore, it is a goal to research and develop a safe and effective therapeutic drug which has significant social benefits and broad market prospects.

"With respect to Thrombocytopenia, there are also treatment theories in Traditional Chinese medicine (TCM) theory. For thrombocytic purpura (1TP), commonly used therapeutic drug are platelet increasing capsules, Weixuening particles, etc. For thrombocytopenia caused by chemotherapy, TCM considers chemotherapeutic drugs is a drastic
drug with pyretic toxicity, and they can consume qi and impair yin, and damage zang-fu viscera such as spleen, kidney and liver, thereby exhausting congenital and postnatal source and resulting in injury of qi and blood, deficiency of liver and kidney, hypofunctioning of spleen and stomach, etc. The most commonly used Traditional Chinese Medicine are Radix et Rhizoma Ginseng, Astragali Radix, Rhizoma Atractylodis Macrocephalae, Angelicae Sinensis Radix, Rehmanniae Radix, Asini Corii Colla, Spatholobii Caulis, Psoraleae Fructus, Lycii Fructus, Ligustri Lucidi Fructus, Agrimoniae Herba, Arachis hypogaea Linn, etc., as well as some compound preparations such as Compound Zaofan pills, and Sheng Ban Recipe.

"Radix et Rhizoma Notoginseng, aslo known as Panax notoginseng or Stephania sinica Diels, is dried roots of panax notoginseng (Burk.) F. H. Chen of Panax of araliaceae. As written in The Compendium of Materia Medica, 'Panax notoginseng has stypticity and analgesia effects, and can stop uncontrollable bleeding due to sword cuts, arrow wounds, falling injury, flogging injury and sore by applying the chewed or powdered Panax notoginseng onto the wounds. Panax notoginseng can also treat diseases such as hematemesis, dysentery characterized by blood in the stool, endometrorrhagia, persistent menstruation, postpartum retention of lochia, dysmenorrheal due to poor blood circulation, swelling and pain of eyes, and tigerbite and snakebite injury'. Referring to The Records of Combination between Traditional Chinese Medicine and Western Medicine. 'Panax notoginseng can dissipate extravasated blood without hurting new blood, which is a marvelous drug for regulating blood.' As referring to New Compilation of Materia Medic), 'Roots of panax notoginseng are miracle cures for stopping bleeding'. Chinese Pharmacopoeia defines the major function of Radix et Rhizoma Notoginseng as 'dissipating stasis and stopping bleeding, diminishing swelling and relieving pain'. Radix et Rhizoma Notoginseng is widely applied to treat internal and external hemorrhage syndrome caused by traumatic injury and internal injury for thousands of years.

"Dencichine (also called Neurotokin, chemical name: .beta.-N-oxalyl-L-.alpha.,.beta.-diaminopropionic acid, referred to as ODAP), is a non-protein amino acid, and is hemostatic active ingredient of Radix et Rhizoma Notoginseng. Rao et al isolated dencichine from a seed of Lathyrus sativus and identified its chemical constitution in 1964, and successfully synthesized the dencichine in 1971, and synchronously researched the relation between the optical activity and central toxicity of dencichine. Hereafter, various synthetic methods were successively reported. At present, the research on central neurotoxicity of Dencichine has gone deep into cellular and molecular level, and it is considered that the central neurotoxicity of dencichine is because that it is an analogue of L-Glutamate which polarizes central nervous system cell membrane and affects activity of ions including Na.sup.+ , K.sup.+ , Ca.sup.2+ , etc.

"In the middle of 1980s, Chinese medicine workers started to research synthesis, pharmacology and toxicology of dencichine. In 1984, Zhao Guoqiang et al., worked in Tianjin Institute of Traditional Chinese Medicine, synthesized dencichine which is the active hemostatic ingredients of Notoginseng Radix et Rhizoma, and researched the effect of dencichine and its enantiomorph of .beta.-N-oxalyl-D-.alpha.,.beta.-diaminopropionic acid on hemostasis, increase of platelet count and neurotoxicity, etc., thus finding out both dencichine and the enantiomorph thereof have a significant effect on the hemostasis and increase of platelet count, etc. Zhao Guoqiang dissolved 1 mg dencichine into 0.5 ml Ringer-Locke solution to prepare a mixed solution, and injected the mixed solution into abdominal cavity of a female mouse, and it was found that dencichine is able to markedly increase the platelet count by 30%. In 1988, Lu Qi et al of Jilin Agricultural University respectively separated dencichine used as hemostatic ingredient from Traditional Chinese Medicine such as Ginseng Radix et Rhizoma, whereby scientifically verifying that Traditional Chinese Medicine such as Ginseng Radix et Rhizoma etc. have hemostasis effect, which was recorded in ancient prescription. Liu Hezhi et al have researched hemostasis mechanism of dencichine, and considered that injection of Notoginseng
Radix et Rhizoma could make thrombocyte generate viscous deformation movement such as stretch, pseudopodia, aggregation, deformation, as a result some cells were broken down or dissolved, and degranulation and secretory response was caused, thereby inducing thrombocyte to release hemostatic active substance such as ADP, platelet factor and calcium ion, so as to achieve the hemostasis purpose.

"With respect to the report that dencichine can increase the platelet count, we carried out experimental research on dencichine for use in treatment of Thrombocytopenia. The results show that it has no obvious change on the platelet count of rabbits by using single-dose injection of dencichine and various doses of drug respectively (see Table 1).

"TABLE-US-00001 TABLE 1 Influence of Dencichine for injection on the platelet count of rabbits(n = 6, mean .+-.. SD) Dose PLT.(times.10.sup.9/L) Group (mg/kg) 0 min 30 min 60 min Sodium -- 529.0 .+-.. 54.2 512.8 .+-.. 54.7 524.8 .+-.. 49.9 chloride injection Reptilase .RTM. 0.3 613.0 .+-.. 118.8 488.5 .+-.. 141.9 519.2 .+-.. 90.5 KU/kg Dencichine 1.00 491.2 .+-.. 163.1 526.5 .+-.. 143.8 541.0 .+-.. 121.6 for injection 0.20 574.0 .+-.. 64.3 502.3 .+-.. 60.8 518.2 .+-.. 128.5 0.04 523.3 .+-.. 78.5 451.0 .+-.. 144.5 504.0 .+-.. 87.8

"In the repeated prophylactic administration process, prophylactic administration for 3 days, 5 days and 7 days respectively, the results show that prophylactic administration of interleukin 11 or dencichine for 5 days and 7 days respectively increase the platelet count (compared with that of model group). The platelet count had no significant difference compared with that of model group by prophylactic administration for 3 days (Table 2).

"TABLE-US-00002 TABLE 2 Influence of dencichine with different administration time on platelet count of rats with thrombocytopenia caused by carboplatin (x .+-.. sD. .times.10.sup.9/L) Injection of Prophylactic Carboplatin Initial value administration for 10 days Blank group 747.0 .+-.. 106.88 635.7 .+-.. 118.11 788.0 .+-.. 147.35 Model group 716.6 .+-.. 62.57 651.3 .+-.. 97.93 115.9 .+-.. 12.71 Prophylactic 732.3 .+-.. 197.06 860.5 .+-.. 113.92 179.5 .+-.. 26.76 administration of interleukin for 7 days Prophylactic 743.7 .+-.. 226.92 772.8 .+-.. 70.63# 166.2 .+-.. 18.20 administration of dencichine for 7 days Prophylactic 724.0 .+-.. 178.87 759.5 .+-.. 145.34 178.3 .+-.. 57.08 administration of interleukin for 5 days Prophylactic 736.2 .+-.. 182.37 773.2 .+-.. 142.02 176.2 .+-.. 28.34 administration of dencichine for 5 days Prophylactic 736.3 .+-.. 175.56 820.7 .+-.. 155.13 88.5 .+-.. 51.49 administration of interleukin for 3 days Prophylactic 717.5 .+-.. 276.94 656.3 .+-.. 67.35 110.2 .+-.. 40.43 administration of dencichine for 3 days

"Pharmacodynamic study further finds that dencichine has a significant effect against decrease of a rat's platelet count caused by carboplatin, which shows the effect for increasing thrombocyte, and simultaneously improving the function of thrombocyte to fight against decrease of thrombocyte aggregation rate of the rat caused by injecting carboplatin, thus increasing thrombocyte aggregation rate. So far, it has been reported that a little dencichine can be used as hemostatic drug in prior art, as disclosed in the patent application with publication No. CN1292376A that administrating a little dencichine can achieve hemostasis. However, it has never been reported that dencichine is able to treat Thrombocytopenia."

Supplementing the background information on this patent, NewsRx reporters also obtained the inventors' summary information for this patent: "The present invention aims to provide a use of dencichine in manufacture of a medicament for the treatment of Thrombocytopenia.

"Preferably, the dencichine is made into an oral preparation or injectable preparation by adding pharmaceutically acceptable conventional excipients, so as to be used in clinical treatment of Thrombocytopenia.

"More preferably, the oral preparation is tablets, capsules, granules or powders; the
injectable preparation is injection liquid or powder injection. Wherein, the oral preparation is preferably dispersible tablets, orally disintegrating tablets or sustained release tablets; the injectable preparation is preferably injection liquid.

"The present invention has following technical effects:
"The present invention first discovers that dencichine can be used for the treatment of Thrombocytopenia. It has been demonstrated that dencichine can effectively inhibit thrombopenia and thrombocytopenic purpura caused by chemotherapy drugs in pharmacodynamic experiments of laboratory, which has significant effects and little side effects."

CH BIOMEDICAL

Patent Issued for Ventricular Assist Device Controller with Integrated Power Source (USPTO 9526819)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- CH BIOMEDICAL (USA), INC. (Torrance, CA) has been issued patent number 9526819, according to news reporting originating out of Alexandria, Virginia, by NewsRx editors.

The patent's inventor is Chen, Chen (Santa Barbara, CA).

This patent was filed on September 26, 2014 and was published online on December 27, 2016.

From the background information supplied by the inventors, news correspondents obtained the following quote: "Ventricular assist devices are blood pumps, which assist blood circulation when a subject's heart is incapable of providing adequate blood circulation. FIG. 1 illustrates a conventional ventricular assist device (VAD) with extra-corporeal power and control components. The VAD 2 is implanted in a subject's body 4 near the heart 3. The VAD 2 is coupled by a percutaneous cable 6 to extra-corporeal components including a controller 8 and a power source. The power source may include and alternating current (AC) power source (not shown) and a pair of rechargeable batteries 10, 12, for example.

"Power cables 14, 16 couple the power sources to the controller 8. Conventionally, one end of each power cable 14, 16 includes a connector coupled to the power source and another end of each power cable 14, 16 includes another connector coupled to the controller 8. Normally, more than one rechargeable battery 10, 12 are coupled to a VAD controller 8, as shown, to provide improved safety. During operation of the VAD 2, when the controller 8 that is supplying power to the VAD 2 is disconnected from an AC power cable (not shown), two
batteries 10, 12 remain coupled to the controller 8 to ensure that sufficient and continuous power is provided to the VAD 2. When one of the rechargeable batteries 10, 12 (e.g., battery 10) is disconnected from the controller 8 to be charged, the other battery (e.g., battery 12) remains connected to the controller 8 and provide uninterrupted power to the controller 8 and blood pump 2. Within a short time after one battery 10 is disconnected from the controller 8, a fully charged standby battery is usually connected to the controller 8 via connecting cables 14. The system then resumes operation with at least two power sources connected to the controller.

"Normally, the two batteries 10, 12 are substantially similar or identical with the same capacity, size and weight. This type of conventional system generally draws power from one battery (e.g. 10) at a time until it is discharged to certain level. Then the system urges the patient to replace the substantially discharged battery with a fully-charged standby battery. During this period, the second battery (e.g. 12), which is connected to the controller, stands idle and remains at full capacity. However, in the conventional system, the time interval between changing batteries is usually determined by the life time of a single battery, rather than the sum of the life time of the two batteries. For example, if one battery 10 lasts five hours, then the patient is typically instructed to change battery every five hours, even though the second battery 12 is still capable of maintaining the system in normal operation for the next five hours. As a result, a patient using the conventional system generally carries a redundant battery of the same size and weight as an operational battery all the time. This causes inconvenience and burden that detrimentally affects the patients' normal activities.

"The conventional configuration as shown in FIG. 1, includes at least three extra-corporeal components including the controller 8, a first rechargeable battery 14 coupled to the controller 8 and a second rechargeable battery 16 separately coupled to the controller 8. These extra-corporeal components, which are carried by the subject, severely limit the subject's mobility and comfort. Moreover, the power cables 14, 16 that are coupled between controller 8 and batteries 10, 12 are prone to mechanical wear and include connectors that may eventually fail after being repeatedly connected and disconnected to the controller 8 and batteries 10, 12, for example, many times in a day every day. It is also possible that a connector of a power cable 14, 16 may loosen or that the power cable may become completely disconnected from the battery 10, 12 or controller 8. These failure modes impose a potentially fatal risk of power interruptions and/or control signal interruptions to a VAD that could prevent the VAD from operating."

Supplementing the background information on this patent, NewsRx reporters also obtained the inventor's summary information for this patent: "Aspects of the present disclosure include an extra-corporeal controller unit for an implantable ventricular assist device (VAD) in which rechargeable batteries and control circuitry are integrated into a single housing. The extra-corporeal components including the controller 8, a first rechargeable battery 14 coupled to the controller 8 and a second rechargeable battery 16 separately coupled to the controller 8. These extra-corporeal components, which are carried by the subject, severely limit the subject's mobility and comfort. Moreover, the power cables 14, 16 that are coupled between controller 8 and batteries 10, 12 are prone to mechanical wear and include connectors that may eventually fail after being repeatedly connected and disconnected to the controller 8 and batteries 10, 12, for example, many times in a day every day. It is also possible that a connector of a power cable 14, 16 may loosen or that the power cable may become completely disconnected from the battery 10, 12 or controller 8. These failure modes impose a potentially fatal risk of power interruptions and/or control signal interruptions to a VAD that could prevent the VAD from operating."

"According to another aspect of the present disclosure, the rechargeable power source includes two or more rechargeable batteries configured in respective battery modules. The battery modules are configured for removable installation in a housing of the controller unit. Mating power connectors are integrated in the battery modules and the housing. The mating connectors are configured to couple each battery to the control circuitry and/or to the percutaneous cable or the transcutaneous energy/signal transmission mechanism whenever the respective battery module containing the battery is installed in the housing.

"These and other features, aspects and advantages of the present disclosure will be
better understood with reference to the following drawings, description and claims."

**Patents**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- From Washington, D.C., NewsRx journalists report that a patent application by the inventors Nagaishi, Michihiro (Suwa-shi, JP); Yamashita, Hideto (Suwa-shi, JP), filed on June 6, 2016, was made available online on December 29, 2016.

No assignee for this patent application has been made.

News editors obtained the following quote from the background information supplied by the inventors: "The present invention relates to an advice generation method, an advice generation program, an advice generation system and an advice generation device."

"It is said that receiving instructions from a good coach or trainer is a short cut to improve skills in sports. In golf, for instance, there are services in which a player receives lessons directly from an instructor called a teaching pro or in which a player sends a video of his/her swings and receives advice on it.

"However, ordinary sports enthusiasts find it hard to spend a lot of time and money on receiving instructions, and often use commercially available practice machines to practice and improve their skills on their own. Many of such practice machines simply capture and display movements of the user who practices, the ball and the like, but such motion analysis alone is not enough for improvement in skills in sports. Thus, a sports practice machine which offers advice on points to be improved as a result of analysis is proposed.

"For example, JP-A-2013-27629 proposes an exercise instruction device which offers advice for instructions according to the physique, movement habits and the like of the user.

"However, even when the advice for instructions is generated according to characteristics of the user, if the content of the training menu indicated by the advice is rigorous for the user, many users find it difficult to continuously execute the proposed menu. Consequently, the user cannot sufficiently benefit from effects that can be achieved by continuous training."

As a supplement to the background information on this patent application, NewsRx correspondents also obtained the inventors' summary information for this patent application: "An advantage of some aspects of the invention is to propose training that is easily acceptable to
the user.

"The invention can be implemented in the following configurations or application examples.

"Application Example 1

An advice generation method according to this application example includes: acquiring personal information about a user; searching for a similar person who is similar to the user on the basis of the personal information; acquiring history information about physical training carried out by the similar person; and generating advice information on the physical training for the user on the basis of the history information.

"According to this method, personal information about the user is acquired and a similar person who is similar to the user is searched for on the basis of the personal information. Then, information about physical training carried out by the similar person is acquired and advice information about the physical training for the user is generated on the basis of the history information. Thus, since the advice information of physical training for the user is generated on the basis of the history information of the physical training carried out by a similar person whose personal information is similar to that of the user, physical training that is suitable for and acceptable to the user can be proposed.

"Application Example 2

In the advice generation method according to the application example, it is preferable that, in the acquisition of the personal information, the personal information including biological information about a biological body and motion information about a movement is acquired.

"According to the method with this configuration, in the acquisition of the personal information, the biological information of the user and the motion information are acquired as personal information. Therefore, information about the biological body of the user and information about the movement can be acquired as personal information.

"Application Example 3

In the advice generation method according to the application example, it is preferable that, in the search, by focusing on profile information including physical fitness information about physical fitness of the user and the personal information, the similar person who has the profile information that is the most similar to that of the user is searched for from information saved in a database.

"According to the method with this configuration, the similar person who has the physical fitness information and personal information that are the most similar to those of the user can be extracted from the information in the database.

"Application Example 4

In the advice generation method according to the application example, it is preferable that, in the acquisition of the history information, the history information including a training item carried out in the physical training and a training duration of the training items is acquired.

"According to the method with this configuration, by acquiring the history information, it is possible to acquire the information of the training item carried out in the physical training by the similar person and the training duration of each training item.

"Application Example 5

In the advice generation method according to the application example, it is preferable that, in the generation, a first training duration for the training item is decided on the basis of the motion information and then a third training duration recommended in the advice
information is decided on the basis of the first training duration that is decided and a second training duration indicated by the history information.

"According to the method with this configuration, the third training duration is decided on the basis of the first training duration decided on the basis of the motion information of the user and the second training duration indicated by the history information of the similar person. Therefore, a training duration that is not unreasonable and is more acceptable to the user can be proposed.

"Application Example 6
"In the advice generation method according to the application example, in the generation, the history information of the similar person may be generated as the advice information.

"Application Example 7
"In the advice generation method according to the application example, the biological information may include at least one of pulse rate, body temperature and blood pressure in the biological body.

"Application Example 8
"In the advice generation method according to the application example, the motion information may include at least one of acceleration and angular velocity generated by a movement of the user.

"Application Example 9
"It is preferable that the advice generation method according to the application example includes outputting the advice information that is generated.

"According to the method with this configuration, the advice information that is generated can be outputted and thus disclosed.

"Application Example 10
"An advice generation program according to this application example causes a computer to execute: a personal information acquisition function of acquiring personal information about a user; a search function of searching for an similar person who is similar to the user on the basis of the personal information; a history information acquisition function of acquiring history information about physical training carried out by the similar person; and a generation function of generating advice information on the physical training for the user on the basis of the history information.

"According to this configuration, personal information about the user is acquired and an similar person who is similar to the user is searched for on the basis of the personal information. Then, history information about physical training carried out by the similar person is acquired and advice information about the physical training for the user is generated on the basis of the history information. Thus, since the advice information of physical training for the user is generated on the basis of the history information of the physical training carried out by the similar person whose personal information is similar to that of the user, physical training that is suitable for and acceptable to the user can be proposed.

"Application Example 11
"An advice generation system according to this application example includes: a personal information acquirer which acquires personal information about a user; a searcher which searches for an similar person who is similar to the user on the basis of the personal information; a history information acquirer which acquires history information about physical training carried out by the similar person; and a generator which generates advice information on the physical training for the user on the basis of the history information.
"According to this configuration, personal information about the user is acquired and an similar person who is similar to the user is searched for on the basis of the personal information. Then, history information about physical training carried out by the similar person is acquired and advice information about the physical training for the user is generated on the basis of the history information. Thus, since the advice information of physical training for the user is generated on the basis of the history information of the physical training carried out by the similar person whose personal information is similar to that of the user, physical training that is suitable for and acceptable to the user can be proposed.

BRIEF DESCRIPTION OF THE DRAWINGS

"The invention will be described with reference to the accompanying drawings, wherein like numbers reference like elements.

"FIG. 1 shows the configuration of an exercise instruction system according to an embodiment of the invention.

"FIG. 2 shows the arrangement of components of the exercise instruction system.

"FIG. 3 shows a sensor module attached to a band.

"FIG. 4 shows the configuration of basic data.

"FIG. 5 explains an arm motion model.

"FIG. 6 shows an example of wearing a sensor module.

"FIG. 7 explains processing of deciding recommended training.

"FIG. 8 is a flowchart showing a flow of processing in the exercise instruction system.

"FIG. 9 shows a modification of the processing of deciding recommended training."
of a vehicle seat having at least one base sheet and a backrest frame comprising a left and a right vertically extending lateral top-hat profile-member and an upper and a lower top-hat profile-member which extends in the transverse direction. The top-hat profile-members are welded to the front side of the base sheet. The lateral top-hat profile-members are welded to the top-hat profile-members which extend in the transverse direction.

"DE 10 2006 000 850 B4 discloses a backrest structure having an integrally constructed, substantially peripheral frame. The frame extends at three edge regions of the base sheet and comprises two longitudinal portions which extend in a parallel manner and a transverse portion which connects the longitudinal portions. In order to increase the rigidity, the base sheet has reinforcement beads. In order to fix and secure a cushion, upholstery suspension channels are provided on the outer edge regions of the base sheet.

"DE 10 2010 054 185 A1 discloses a backrest having a frame which is constructed in several portions. The frame comprises two longitudinal struts which extend in a parallel manner along the lateral edge regions of the base sheet. A transverse strut is arranged along the upper edge region. In order to reinforce the base sheet, bead-like channels are impressed.

"DE 10 2005 001 606 B4 discloses a backrest structure having an integrally constructed frame sheet which extends over a large portion of the surface of the base sheet. The frame sheet and the base sheet are connected to each other by means of laser welding. In this instance, a laser beam penetrates the base sheet and the surface of the frame sheet, whereby a weld seam which welds the base sheet to the frame sheet is produced.

"DE 35 15 598 C2 discloses a weld connection of two thin metal sheets which form an inner and an outer sheet, for example, an inner and an outer sheet for doors and/or hatches in motor vehicles, wherein the outer sheet (2) forms a visually smooth outer face and is flanged in the edge region thereof. The outer sheet is flanged through 180.degree. on the rear face thereof, and the inner sheet is placed with an edge region on the flanged edge of the outer sheet. The connection between this sheet and the flanged edge is carried out by means of a laser beam from the side facing away from the outer face.

"Base sheets having a material thickness of 0.6 mm and more are generally used in the production of backrest structures. The trend in vehicle seat development is toward lightweight construction. Large sheet components, such as base sheets of backrest structures, have a very high weight proportion of the overall backrest. As a result of the large surface areas of the base sheets, a large amount of material is provided, which results in the high weight. Since the surface-areas of the sheet components cannot be reduced, with a predetermined material, for example, sheet steel, only the sheet thickness of the sheets can be reduced in order to save weight. Thus, the sheet thickness of large sheet components has in the past been continuously reduced. Below a sheet thickness of approximately 0.6 mm, however, weldability of the sheets is no longer ensured in a simple manner since too little material is available. As a result of the small material thickness, there is the risk during the welding process that the laser beam may burn a hole in the base sheet, whereby the sheet becomes damaged and is not welded to the frame. Adapters cannot readily be fitted to the thin sheets. The sheets which are becoming increasingly thin additionally involve an increased risk of injury during handling and further processing."

As a supplement to the background information on this patent application, NewsRx correspondents also obtained the inventors' summary information for this patent application:

"An object of the invention is to provide a backrest structure for a vehicle seat having a relatively thin base sheet and thereby reduced weight and a vehicle seat having reduced weight."

"A backrest structure of the generic type comprises a planar base sheet and an additional structural component which are connected to each other by means of laser welding
using at least one weld seam. The term 'planar' is intended in particular to be understood to mean substantially flat. However, individual geometries such as reinforcement beads require a deviation from an absolutely flat shape. The term 'weld seam' is also intended to be understood to refer to weld seams whose length substantially corresponds to the width. Consequently, weld seams also include weld spots.

"According to the invention, there is provision in the region of the at least one weld seam for at least one tongue of the base sheet to be bent through 180° and placed on the remaining base sheet, and for the at least one weld seam to connect the bent tongue, the remaining base sheet and the additional structural component to each other. Consequently, the weld seam extends over the bent part-region, the remaining base sheet and the additional structural component.

"As a result of the bending of the at least one tongue of the base sheet, a doubled material thickness of the base sheet is produced locally. As a result of the doubled material thickness, a weld seam can be produced in a simplified manner by means of laser welding. The risk that the laser beam may burn a hole in the base sheet is reduced. Also, any air gap which may remain between the base sheet and the tongue does not influence the laser welding operation or has only an insignificant influence. Consequently, a relatively thin base sheet with reduced weight can be used, whereby the vehicle seat also has a reduced weight. Furthermore, the production costs are reduced and the efficiency is thereby increased.

"According to an advantageous development of the invention, the at least one tongue is bent multiple times through 180° and placed on the remaining base sheet. The material thickness of the base sheet is thereby not only doubled but multiplied. As a result of the multiplied material thickness of the base sheet, a weld seam can be produced in an even more simplified manner by means of laser welding.

"An advantageous saving of weight is achieved when the base sheet has a material thickness of less than 0.5 mm. Preferably, the base sheet has a material thickness between 0.3 mm and 0.5 mm, in a particularly preferred manner of approximately 0.35 mm. This material thickness brings about an advantageous saving of weight and nonetheless enables safe production of a weld seam by means of laser welding.

"According to a preferred embodiment of the invention, the additional structural component is a backrest frame.

"The rigidity of the backrest structure can be increased by a plurality of bent tongues being arranged along an outer contour of the base sheet and being welded to the backrest frame. The spacings between individual tongues may be equidistant. However, the spacings between individual tongues may also be adapted to the loading of the backrest structure.

"According to an advantageous embodiment, the bent tongue is a rectangular tongue which is separated at three sides from the remaining base sheet and which is bent through 180°, at the fourth side which is connected to the remaining base sheet and placed on the remaining base sheet. Such a tongue can be produced in a relatively simple manner by means of punching from the base sheet at any location.

"According to another advantageous embodiment, the bent part-region is edge material which is located at the edge of the base sheet and which is in particular tongue-like. The punching operation can thereby be dispensed with and there is locally produced a relatively large securing region which is located at the edge of the base sheet.

"The base sheet may have at least one securing location which is inwardly spaced apart from the outer contour thereof. This may be supplemented by a securing region in the region of the outer contour of the base sheet. It is thus possible, for example, for backrest frames, which are provided as a top-hat profile-member with two securing flanges which extend
in a parallel manner, to be secured to the base sheet. Preferably, the securing locations each comprise a passage region and a tongue.

"If the edge material is simply bent through 180°, there is produced a flat edge contour, which does not have a sharp-edged but instead a rounded edge region. The risk of injury when a backrest structure is produced is thereby reduced.

"If the edge material is bent several times, wherein the edge material and the remaining base sheet enclose a geometric shape, a contoured edge contour is produced. The contoured edge contour also reduces the risk of injury since it does not have a sharp-edged, but instead a rounded edge region. In addition, the contoured edge contour increases the rigidity of the base sheet.

"According to an advantageous development of the invention, the backrest frame has an upholstery suspension channel for securing a cushion. It is consequently not necessary to provide an upholstery suspension channel on the base sheet and, consequently, the base sheet does not need to absorb the load resulting from the tension of the cushion and, consequently, a base sheet having a relatively thin material thickness can be used.

"According to another development of the invention, the base sheet additionally has an upholstery suspension region which is preferably integrated in the upholstery suspension channel of the backrest frame in a positive-locking manner. The rigidity of the upholstery suspension channel is thereby increased.

"The rigidity of the upholstery suspension channel is increased even further when the base sheet is doubled in the region of the upholstery suspension region.

"The rigidity of the base sheet can be increased by means of at least one reinforcement bead. Preferably, the base sheet is produced from sheet steel or sheet aluminum.

"According to another preferred embodiment of the invention, the additional structural component is a wire, in particular a Top Tether clip of an Isofix child seat securing system.

"The object is also achieved with a vehicle seat which comprises at least one backrest structure according to the invention.

"The invention is explained in greater detail below with reference to advantageous embodiments illustrated in the figures. However, the invention is not limited to these embodiments. The various features of novelty which characterize the invention are pointed out with particularity in the claims annexed to and forming a part of this disclosure. For a better understanding of the invention, its operating advantages and specific objects attained by its uses, reference is made to the accompanying drawings and descriptive matter in which preferred embodiments of the invention are illustrated.

BRIEF DESCRIPTION OF THE DRAWINGS

"In the drawings:

"FIG. 1 is a schematic, partially sectioned view of a vehicle seat;

"FIG. 2 is a perspective view of a backrest structure of the vehicle seat according to FIG. 1 according to a first embodiment;

"FIG. 3 is a view of a base sheet of the backrest structure according to FIG. 2;

"FIG. 4 is an enlarged illustration of the marked part-region of the base sheet according to FIG. 3;

"FIG. 5 is a sectional view taken along the line A-A from FIG. 4, wherein a portion of the frame is additionally illustrated;
"FIG. 6 is a view of a backrest structure of the vehicle seat according to FIG. 1 according to a second embodiment, when viewed in the travel direction;
"FIG. 7 is a sectional view taken along the line B-B from FIG. 6;
"FIG. 8 is a sectional view through a securing region of a base sheet according to a first configuration of the second embodiment;
"FIG. 9 is a sectional view through a securing region of a base sheet according to a second configuration of the second embodiment;
"FIG. 10 is a perspective view of a backrest structure of the vehicle seat according to FIG. 1 according to a third embodiment with a Top Tether clip; and
"FIG. 11 is a sectional view taken along line C-C from FIG. 10."

**Researchers Submit Patent Application, "Cancer Immunotherapy by Radiofrequency Electrical Membrane Breakdown (Rf-Emb)"**, for Approval (USPTO 20160367310)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- From Washington, D.C., NewsRx journalists report that a patent application by the inventors Onik, Gary M. (Ft. Lauderdale, FL); Miessau, James A. (Branford, CT), filed on December 5, 2014, was made available online on December 29, 2016. No assignee for this patent application has been made.

News editors obtained the following quote from the background information supplied by the inventors: "The present invention relates generally to the field of medical ablation of biological tissue for treatment of disease and, more particularly, to the controlled application of radio frequency energy to soft tissue and cancerous tissue in humans and mammals to ablate such tissue through cellular destruction by Electrical Membrane Breakdown.

"Cancer is not one single disease but rather a group of diseases with common characteristics that often result in sustained cell proliferation, reduced or delayed cell mortality, cooption of bodily angiogenesis and metabolic processes and evasion of bodily immune response which results in undesirable soft tissue growths called neoplasms or, more commonly, tumors. Removal or destruction of this aberrant tissue is a goal of many cancer treatment methods and modalities. Surgical tumor excision is one method of accomplishing this goal. Tissue ablation is another, minimally invasive method of destroying undesirable tissue in the body, and has been generally divided into thermal and non-thermal ablation technologies. Thermal ablation encompasses both the addition and removal of heat to destroy undesirable cells. Cryoablation is a well established technique that kills cells by freezing of the extracellular
compartment resulting in cell dehydration beginning at -15 C and by intracellular ice formation causing membrane rupture occurring at colder temperatures. Because cryoablative techniques can rupture the cell membrane without denaturing cell proteins under certain conditions, such techniques have the additional ability to stimulate an antitumor immune response in the patient.

"Heat based techniques are also well established for ablation of both cancerous and non-cancerous tissues and include radio-frequency (RF) thermal, microwave and high intensity focused ultrasound ablation which raise localized tissue temperatures well above the body's normal 37.0°C. These methods use various techniques to apply energy to the target cells to raise interstitial temperature. For example, RF thermal ablation uses a high frequency electric field to induce vibrations in the cell membrane that are converted to heat by friction. Cell death occurs in as little as 30 second once the cell temperature reaches 50.0°C and decreases as the temperature rises. At 60.0°C, cell death is instantaneous. If the intracellular temperature rises to between about 60 and 95.0°C, the mechanisms involved in cell death include cellular desiccation and protein coagulation. When the intracellular temperature reaches 100.0°C, cellular vaporization occurs as intracellular water boils to steam. In the context of tissue ablation, cell temperatures not exceeding 50.0°C are not considered clinically significant. Because cellular proteins are denatured by the heat of thermal ablation techniques, they are not available to stimulate a specific immune response as they may be with cryoablation. Both heat based and cryoablation techniques suffer from the drawback that they have little or no ability to spare normal structures in the treatment zone and so can be contraindicated based on tumor location or lead to complications from collateral injury.

"Non thermal ablation techniques include electrochemotherapy and irreversible electroporation which although quite distinct from one another, each rely on the phenomenon of electroporation. With reference to FIG. 1, electroporation refers to the fact that the plasma membrane of a cell exposed to high voltage pulsed electric fields within certain parameters, becomes temporarily permeable due to destabilization of the lipid bilayer and the formation of pores P. The cell plasma membrane consists of a lipid bilayer with a thickness t of approximately 5 nm. With reference to FIG. 2A, the membrane acts as a nonconducting, dielectric barrier forming, in essence, a capacitor. Physiological conditions produce a natural electric potential difference due to charge separation across the membrane between the inside and outside of the cell even in the absence of an applied electric field. This resting transmembrane potential V'm ranges from 40 mV for adipose cells to 85 mV for skeletal muscle cells and 90 mV cardiac muscle cells and can vary by cell size and ion concentration among other things.

"With continued reference to FIGS. 2B-2D, exposure of a cell to an externally applied electric field E induces an additional voltage V across the membrane as long as the external field is present. The induced transmembrane voltage is proportional to the strength of the external electric field and the radius of the cell. Formation of transmembrane pores P in the membrane occurs if the cumulative resting and applied transmembrane potential exceeds the threshold voltage which may typically be between 200 mV and 1 V. Poration of the membrane is reversible if the transmembrane potential does not exceed the critical value such that the pore area is small in relation to the total membrane surface. In such reversible electroporation, the cell membrane recovers after the applied field is removed and the cell remains viable. Above a critical transmembrane potential and with longer exposure times, poration becomes irreversible leading to eventual cell death due an influx of extracellular ions resulting in loss of homeostasis and subsequent apoptosis. Pathology after irreversible electroporation of a cell does not show structural or cellular changes until 24 hours after field exposure except in certain very limited tissue types. However, in all cases the mechanism of cellular destruction and death by IRE is apoptotic which requires considerable time to pass and is not visible pathologically in a time
frame to be clinically useful in determining the efficacy of IRE treatment which is an important clinical drawback to the method.

"Developed in the early 1990's, electrochemotherapy combines the physical effect of reversible cell membrane poration with administration of chemotherapy drugs such as cisplatin and bleomycin. By temporarily increasing the cell membrane permeability, uptake of non-permeant or poorly permeant chemotherapeutic drugs is greatly enhanced. After the electric field is discontinued, the pores close and the drug molecules are retained inside the target cells without significant damage to the exposed cells. This approach to chemotherapy grew out of earlier research developing electroporation as a technique for transfection of genes and DNA molecules for therapeutic effect. In this context, irreversible electroporation leading to cell death was viewed as a failure in as much as the treated cells did not survive to realize the modification as intended.

"Irreversible electroporation (IRE) as an ablation method grew out of the realization that the 'failure' to achieve reversible electroporation could be utilized to selectively kill undesired tissue. IRE effectively kills a predictable treatment area without the drawbacks of thermal ablation methods that destroy adjacent vascular and collagen structures. During a typical IRE treatment, one to three pairs of electrodes are placed in or around the tumor. Electrical pulses carefully chosen to induce an electrical field strength above the critical transmembrane potential are delivered in groups of 10, usually for nine cycles. Each 10-pulse cycle takes about one second, and the electrodes pause briefly before starting the next cycle. As described in U.S. Pat. No. 8,048,067 to Rubinsky, et. al and application Ser. No. 13/332,133 by Arena, et al. which are incorporated here by reference, the field strength and pulse characteristics are chosen to provide the necessary field strength for IRE but without inducing thermal effects as with RF thermal ablation. However, because cells ablated by IRE methods undergo apoptotic death without membrane rupture their ability to induce a supplemental immune response as observed with cryoablation is impaired. When used as the sole ablative tool in a treatment protocol, IRE's inability to induce a supplemental immune response is a substantial limitation to its therapeutic benefit for patients. On the other hand, cryoablation suffers from the significant clinical disadvantages arising from the extreme cold and its capacity to destroy nearby critical healthy structures. What is needed is a minimally invasive tissue ablation technology that can avoid damaging healthy tissue while exposing cellular contents without denaturing such cellular contents so that they can to trigger a clinically useful immune response."

As a supplement to the background information on this patent application, NewsRx correspondents also obtained the inventors' summary information for this patent application: "It is, therefore, an object of the present invention to provide a method of tissue ablation using electrical pulses which causes immediate cell death through the mechanism of complete break down the membrane of the cell.

"It is another object of the present invention to provide a method of tissue ablation that causes immediate cell death electrically breaking down the cell membrane such that it can be monitored by immediate pathologic, chemical or spectroscopic examination of the tissue to evaluate efficacy of the treatment and adjust the same as needed.

"It is yet another object of the present invention to provide a method of tissue ablation using electrical pulses that causes immediate cellular membrane breakdown non-thermally so that sensitive tissue structures are spared and the intra-cellular and membrane proteins are spilled into the extracellular space without denaturing to be exposed to the body's immune system in order to illicit a specific tumor immune response.

"It is yet another object of the present invention to provide a method of tissue ablation that exposes non-denatured intra-cellular and membrane proteins to the immune system
to illicit a specific tumor immune response which can be modulated and enhanced by a variety of additional immune modulators.

"According to the present invention, the above described and other objects are accomplished, by applying to undesirable tissue in the body an external electric field specifically configured to directly and completely disintegrate the cell membrane. Referre to as Electrical Membrane Breakdown (EMB), application of an external oscillating electric field causes vibration and flexing of the cell membrane which results in a dramatic and immediate mechanical tearing or rupturing the cell membrane. EMB applies significantly higher energy levels than prior art methods to rupture the cell membrane rather than to electroporate the cell membrane. Unlike prior art methods, EMB expels the entire contents of the cell into the extracellular fluid and exposes internal components of the cell membrane which induces an immunologic response by the subject.

"A system for generation of the electric field necessary to induce EMB includes a bipolar pulse generator operatively coupled to a controller for controlling generation and delivery of the electrical pulses necessary to generate an appropriate electric field. The field is generated by therapeutic probes placed in proximity to the soft tissue or cancerous cells within the body of the subject and the bipolar pulses are shaped, designed and applied to achieve that result in an optimal fashion. A temperature probe may be provided for temperature feedback to the controller which is configured to control the signal output characteristics of the signal generator. The EMB protocol calls for a series of short and intense bi-polar electric to generate an oscillating electric field between the electrodes that induce a similarly rapid and oscillating buildup of transmembrane potential across the cell membrane. The built up charge applies a an oscillating and flexing force to the cellular membrane which upon reaching a critical value causes extensive rupture of the membrane and spillage of the cellular content. In addition to being bi-polar, the electric pulses preferably trace a square wave form and are characterized by instant charge reversal that have substantially no relaxation time between the positive and negative polarities of the bi-polar pulse. Instant charge reversal pulses are significantly more effective in destruction of dielectric cell membranes

"Important characteristic of the applied electric field include the field strength (Volts/cm), frequency, polarity, shape, duration, number and spacing. Field strength (Volts/cm) is a function of both the applied voltage and the electrode spacing and is preferably in the range of 1,500 V/cm to 10,000 V/cm absent thermal considerations. RF-EMB ablation is preferably performed by application of a series of not less than 100 electric pulses in a pulse train so as to impart the energy necessary on the target tissue without developing thermal issues in any clinically significant way. The pulse duration is preferably from 100 to 1000 .mu.s. The relationship between the duration and frequency of each pulse determines the number of instantaneous charge reversals experienced by the cell membrane during each pulse. The duration of each inter pulse burst interval is determined by the controller based on thermal considerations. Real time temperature feedback of the treatment site may be provided to the controller by which the controller can modulate treatment parameters to eliminate thermal effects as desired. Current flow at the treatment site may also be monitored for this purpose.

"The EMB ablation method is carried out by first identifying the location of the soft tissue within the subject to be ablated by medical imaging techniques such as CT or MRI or other means. A preferred position and spacing of the electrodes relative to the target tissue is determined and from 1 to 6 needle electrodes connected to the controller and signal generator are inserted into position in and around the treatment site. Placement and positioning of the electrodes is confirmed by medical imaging and the pulse generator is activated to apply electrical pulses to the electrodes to generate the treatment field thereby causing electrical membrane breakdown of cells in the soft tissue.
"Electrical membrane breakdown causes immediate spillage of all intracellular components of the ruptured cells into an extracellular space and exposes the internal constituent parts of the cell and cell membrane including antigens which induce an immunologic response to destroy and remove this and like material in the body of the subject. The immunologic response can be enhanced by administration of agents that increase the immunologic response process including drugs. Electrical membrane breakdown causes immediate, visually observable tissue change, cellular membrane destruction and cell death such that the method may include the biopsy of a portion of the treated target tissue to verify treatment efficacy immediately after completion of the treatment while the patient is still in position for additional treatment. In other embodiments needle probes placed in critical treatment locations could monitor various parameters by means of chemical or spectroscopic means related to the immediate destruction and spillage of the intra-cellular contents also to verify treatment efficacy. In some situation, the mode of treatment may be switched from EMB to thermal ablation without removal or repositioning of the electrodes by reconfiguring the signal generated by the pulse generator to increase the tissue temperature at the electrodes according to known RF thermal techniques.

BRIEF DESCRIPTION OF THE DRAWINGS
"FIG. 1 is a diagram of a cell membrane pore.
"FIG. 2 is a diagram of cell membrane pore formation by a prior art method.
"FIG. 3 is a comparison of a prior art charge reversal with an instant charge reversal according to the present invention.
"FIG. 4 is a square wave from instant charge reversal pulse according to the present invention.
"FIG. 5 is a diagram of the forces imposed on a cell membrane as a function of electric field pulse width according to the present invention.
"FIG. 6 is a diagram of a prior art failure to deliver prescribed pulses due to excess current.
"FIG. 7 is a schematic diagram of a feedback loop according to the present invention by which a controller reduces an applied signal voltage to keep the current amperage at or below a maximum.
"FIG. 8 is a diagram of a reduction in applied signal voltage upon reaching a maximum current level to permit continued signal delivery according to the present invention.
"FIG. 9 is a schematic diagram of a pulse generation and delivery system for application of the method of the present invention.
"FIG. 10 is a diagram of the parameters of a partial pulse train according to the present invention.
"FIG. 11 is a chart of exemplary treatment protocol parameters according to the present invention.
"FIG. 12 is a diagram of the parameters of exemplary treatment protocol number 1.
"FIG. 13 is a diagram of the parameters of exemplary treatment protocol number 2.
"FIG. 14 is a diagram of the parameters of exemplary treatment protocol number 3.
"FIG. 15 is a diagram of the parameters of exemplary treatment protocol number 4."

Researchers Submit Patent Application, "Co-Crystals, Salts and Solid Forms of Tenofovir Alafenamide", for Approval (USPTO 20160368938)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- From Washington, D.C., NewsRx journalists report that a patent application by the inventors Shi, Bing (Redwood City, CA); Su, Zhuoyi (Edmonton, CA); Wang, Fang (Foster City, CA), filed on June 13, 2016, was made available online on December 29, 2016.

No assignee for this patent application has been made.

News editors obtained the following quote from the background information supplied by the inventors: "Tenofovir alafenamide (TAF) is a nucleotide reverse transcriptase inhibitor useful for the treatment and prevention of HIV and HBV. TAF hemifumarate is described in U.S. Pat. No. 8,754,065 (incorporated by reference herein in its entirety). U.S. Pat. No. 6,043,230 (incorporated by reference herein in its entirety) and other publications describe the antiviral specificity of nucleotide analogs, such as tenofovir disoproxil."

As a supplement to the background information on this patent application, NewsRx correspondents also obtained the inventors’ summary information for this patent application: "The present disclosure provides co-crystals, salts and crystalline forms of tenofovir alafenamide and methods for the preparation, use and isolation of such forms.

"Some embodiments provide tenofovir alafenamide sesquifumarate and crystal forms thereof. Some embodiments provide tenofovir alafenamide sesquifumarate solvates and crystal forms thereof wherein the solvent is selected from the group consisting of isopropanol, methyl ethyl ketone, tetrahydrofuran and acetone.

"Another embodiment provides tenofovir alafenamide oxalate and crystal forms thereof. Another embodiment provides tenofovir alafenamide malonate and crystal forms thereof. Another embodiment provides tenofovir alafenamide L-malate and crystal forms thereof. Another embodiment provides tenofovir alafenamide saccharin and crystal forms thereof. Another embodiment provides tenofovir alafenamide muate and crystal forms thereof. Another embodiment provides tenofovir alafenamide maleate and crystal forms thereof. Another embodiment provides tenofovir alafenamide hydrochloride and crystal forms thereof. Another embodiment provides tenofovir alafenamide ethanesulfonate and crystal forms thereof. Another embodiment provides tenofovir alafenamide benzenesulfonate and crystal forms thereof.

"Another embodiment provides a crystal form of tenofovir alafenamide methanesulfonate, wherein the XRPD pattern comprises 2theta values of 8.7+.0.2, 9.9+.0.2, 10.1+.0.2, and 19.7+.0.2. Another embodiment provides a crystal form of tenofovir alafenamide methanesulfonate having an XRPD substantially as shown in FIG. 16a.

"Another embodiment provides a crystal form of tenofovir alafenamide
methanesulfonate, wherein the XRPD pattern comprises 2theta values of 9.0, 9.5, 18.6, and 22.4+-0.2. Another embodiment provides a crystal form of tenofovir alafenamide methanesulfonate having an XRPD substantially as shown in FIG. 16b.

"Another embodiment provides tenofovir alafenamide sulfate and crystal forms thereof.

"In some embodiments, is provided a pharmaceutical composition comprising the co-crystals, salts and/or crystal forms of tenofovir alafenamide disclosed herein and a pharmaceutically acceptable excipient.

"In some embodiments, is provided a method for treating an HIV infection comprising administering to a subject in need thereof a therapeutically effective amount of the co-crystals, salts and/or crystal forms of tenofovir alafenamide disclosed herein.

"In some embodiments, is provided a method for treating a hepatitis B virus (HBV) infection comprising administering to a subject in need thereof a therapeutically effective amount of the co-crystals, salts and/or crystal forms of tenofovir alafenamide disclosed herein.

"In some embodiments, are provided co-crystals, salts and/or crystal forms of tenofovir alafenamide disclosed herein or a composition thereof, for use in the prophylactic or therapeutic treatment of HIV.

"In some embodiments, are provided co-crystals, salts and/or crystal forms of tenofovir alafenamide disclosed herein or a composition thereof, for use in the prophylactic or therapeutic treatment of HBV.

BRIEF DESCRIPTION OF THE DRAWINGS

"FIG. 1. Presented in FIG. 1 is the experimental X-ray powder diffraction (XRPD) pattern of TAF sesquifumarate isopropanol solvate

"FIG. 2. Presented in FIG. 2 is the experimental X-ray powder diffraction (XRPD) pattern of TAF sesquifumarate methyl ethyl ketone solvate

"FIG. 3. Presented in FIG. 3 is the experimental X-ray powder diffraction (XRPD) pattern of TAF sesquifumarate THF solvate

"FIG. 4. Presented in FIG. 4 is the experimental X-ray powder diffraction (XRPD) pattern of TAF sesquifumarate acetone solvate

"FIG. 5. Presented in FIG. 5 is the Experimental X-ray powder diffraction (XRPD) pattern of TAF sesquifumarate

"FIG. 6. Presented in FIG. 6 is the experimental X-ray powder diffraction (XRPD) pattern of TAF oxalate

"FIG. 7. Presented in FIG. 7 is the Experimental X-ray powder diffraction (XRPD) pattern of TAF malonate

"FIG. 8. Presented in FIG. 8 is the experimental X-ray powder diffraction (XRPD) pattern of TAF L-malate

"FIG. 9. Presented in FIG. 9 is the experimental X-ray powder diffraction (XRPD) pattern of TAF saccharin

"FIG. 10. Presented in FIG. 10 is the experimental X-ray powder diffraction (XRPD) pattern of TAF mucate pattern 1

"FIG. 11. Presented in FIG. 11 is the experimental X-ray powder diffraction (XRPD) pattern of TAF mucate pattern 2

"FIG. 12. Presented in FIG. 12 is the experimental X-ray powder diffraction (XRPD) pattern of TAF maleate
FIG. 13. Presented in FIG. 13 is the experimental X-ray powder diffraction (XRPD) pattern of TAF hydrochloride.

FIG. 14. Presented in FIG. 14 is the experimental X-ray powder diffraction (XRPD) pattern of TAF ethanesulfonate.

FIG. 15. Presented in FIG. 15 is the experimental X-ray powder diffraction (XRPD) pattern of TAF benzenesulfonate.

FIG. 16a. Presented in FIG. 16a is the experimental X-ray powder diffraction (XRPD) pattern of TAF methanesulfonate pattern 1.

FIG. 16b. Presented in FIG. 16b is the Experimental X-ray powder diffraction (XRPD) pattern of TAF methanesulfonate pattern 2.

FIG. 17. Presented in FIG. 17 is the experimental X-ray powder diffraction (XRPD) pattern of TAF sulfate.

FIG. 18. Presented in FIG. 18 is the experimental differential scanning calorimetry (DSC) and Thermo-gravimetric Analysis (TGA) thermograms of tenofovir alafenamide hydrochloride.

FIG. 19. Presented in FIG. 19 is the experimental differential scanning calorimetry (DSC) thermogram of tenofovir alafenamide oxalate.

FIG. 20. Presented in FIG. 20 is the experimental Thermo-gravimetric Analysis (TGA) thermogram of tenofovir alafenamide oxalate.

FIG. 21. Presented in FIG. 21 is the experimental differential scanning calorimetry (DSC) of TAF sesquifumarate isopropanol solvate.

FIG. 22. Presented in FIG. 22 is the experimental differential scanning calorimetry (DSC) of TAF sesquifumarate.

FIG. 23. Presented in FIG. 23 is the experimental differential scanning calorimetry (DSC) and Thermo-gravimetric Analysis (TGA) of TAF saccharin.

FIG. 24. Presented in FIG. 24 is the experimental differential scanning calorimetry (DSC) and Thermo-gravimetric Analysis (TGA) of TAF malonate.

FIG. 25. Presented in FIG. 25 is the experimental differential scanning calorimetry (DSC) and Thermo-gravimetric Analysis (TGA) of TAF L-malate.

FIG. 26. Presented in FIG. 26 is the experimental differential scanning calorimetry (DSC) and Thermo-gravimetric Analysis (TGA) of TAF sulfate.

FIG. 27. Presented in FIG. 27 is the experimental differential scanning calorimetry (DSC) and Thermo-gravimetric Analysis (TGA) of TAF maleate.

FIG. 28. Presented in FIG. 28 is the experimental differential scanning calorimetry (DSC) and Thermo-gravimetric Analysis (TGA) of TAF ethanesulfonate.

FIG. 29. Presented in FIG. 29 is the experimental differential scanning calorimetry (DSC) and Thermo-gravimetric Analysis (TGA) of TAF benzenesulfonate.

FIG. 30. Presented in FIG. 30 is the experimental differential scanning calorimetry (DSC) and Thermo-gravimetric Analysis (TGA) of TAF methanesulfonate pattern 1.

FIG. 31. Presented in FIG. 31 is the experimental differential scanning calorimetry (DSC) and Thermo-gravimetric Analysis (TGA) of TAF mucate Pattern 1 (RC-947-20-38) and Pattern 2 (RC-947-20-37).

FIG. 32. Presented in FIG. 32 is the experimental differential scanning calorimetry (DSC) and Thermo-gravimetric Analysis (TGA) of TAF p-toluene sulfonate.

FIG. 33. Presented in FIG. 33 is the experimental Thermo-gravimetric Analysis of tenofovir alafenamide sesquifumarate IPA solvate (pattern 1).
"FIG. 34. Presented in FIG. 34 is the experimental Thermo-gravimetric Analysis of tenofovir alafenamide sesquifumarate MEK solvate (pattern 2)"

"FIG. 35. Presented in FIG. 35 is the experimental Thermo-gravimetric Analysis of tenofovir alafenamide sesquifumarate THF solvate (pattern 3)"

"FIG. 36. Presented in FIG. 36 is the experimental Thermo-gravimetric Analysis of tenofovir alafenamide sesquifumarate acetone solvate (pattern 4)"

"FIG. 37. Presented in FIG. 37 is the experimental Thermo-gravimetric Analysis of tenofovir alafenamide sesquifumarate (pattern 5)"

University of Southern California

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- From Washington, D.C., NewsRx journalists report that a patent application by the inventors HOFMAN, Florence M. (Venice, CA); FERREIRA, Raquel M.S. (Braga, PT); GIANNOTTA, Steven L. (Pasadena, CA); CHEN, Thomas C. (La Canada Flintridge, CA), filed on March 11, 2015, was made available online on December 29, 2016. The patent's assignee is University of Southern California.

News editors obtained the following quote from the background information supplied by the inventors: "All publications cited herein are incorporated by reference in their entirety to the same extent as if each individual publication or patent application was specifically and individually indicated to be incorporated by reference. The following description includes information that may be useful in understanding the present invention. It is not an admission that any of the information provided herein is prior art or relevant to the presently claimed invention, or that any publication specifically or implicitly referenced is prior art.

"The systemic delivery of miRNA without transfection reagents (naked delivery) has been successfully accomplished for the reduction of tumor metastasis in the mouse liver, by showing that naked miRNA can be internalized by tumor cells. In addition, intravenous injection of naked miRNA was shown to also enter virally infected liver cells. These applications were focused solely on the systemic delivery of miRNA into highly vascularized liver as the target organ, and not relevant to the neurovasculature.

"Cerebral Arteriovenous Malformations (AVM) are brain vascular lesions
comprising an abnormal tangle of vessels (nidus), in which arteries and veins are directly connected without an intervening capillary system. AVM affect approximately 300,000 people in the USA and can lead to serious neurological symptoms or death. Current medical treatments are highly invasive and can pose significant risks to nearby brain structures that regulate speech, movement and sensory processing, highlighting the importance of developing more efficacious and safer therapies.

As a supplement to the background information on this patent application, NewsRx correspondents also obtained the inventors’ summary information for this patent application: "Human AVM-derived brain endothelial cells (AVM-BEC) have distinct and abnormal characteristics compared to normal BEC. Namely, AVM-BEC proliferate more rapidly, migrate faster, and produce aberrant vessel-like structures as compared to normal vasculature. AVM-BEC also express low levels of a key regulator of angiogenesis, thrombospondin-1 (TSP-1). These abnormal features are ameliorated with microRNA-18a (miR-18a) treatment. MiRNAs are small non-coding RNAs that inhibit gene expression by inducing cleavage or translational repression of messenger RNA (mRNA). Specifically, miR-18a inhibited TSP-1 transcriptional repressor, Inhibitor of DNA-binding protein-1 (Id-1), leading to increased TSP-1 levels and decreased vascular endothelial growth factor (VEGF)-A and VEGF-D secretion. miR-18a also regulated cell proliferation and improved tubule formation efficiency. Importantly, these effects were obtained with miRNA alone (naked delivery), in the absence of traditional transfection reagents, like lipofectamine, which cannot be used in vivo due to induced toxicity. Naked miRNAs have been shown to form complexes with circulating RNA-binding proteins, such as argonaute-2 (Ago-2), a member of the Argonaute protein family, which also includes Ago-1, Ago-3 and Ago-4. In human cells, Ago-2 takes part in the RNA-induced silencing complex (RISC) to promote endonucleolytic cleavage of mRNA.

"In this application, we show that AVM-BEC release Ago-2, which can be used to enhance the entry of extracellular miR-18a into brain endothelial cells. In vitro studies show that Ago-2 in combination with miR-18a is functional and able to stimulate TSP-1 production. Furthermore, miR-18a in combination with Ago-2 can be delivered in vivo by intravenous administration, resulting in increased circulating serum TSP-1 and decreased VEGF-A. Thus Ago-2 may be used to decrease angiogenic activity in brain endothelial cells, making Ago-2 a biocompatible miRNA-delivery platform suitable for treating neurovascular diseases and brain tumors.

"Various embodiments of the present invention provide a method of delivering a miRNA to a cell. The method may comprise or may consist of: providing the miRNA and an Ago-2 or a variant thereof; and contacting the cell with the miRNA and the Ago-2 or the variant thereof, thereby delivering the mRNA to the cell. In some embodiments, the miRNA and the Ago-2 or the variant thereof are provided in one composition. In other embodiments, the miRNA and the Ago-2 or the variant thereof are provided in separate compositions. Various embodiments of the present invention provide a kit for delivering a miRNA to a cell. The kit may comprise or may consist of a quantity of a miRNA; a quantity of an Ago-2 or a variant thereof; and instructions for using the Ago-2 or the variant thereof to deliver the miRNA.

"Various embodiments of the present invention provide a method of delivering a miRNA to a cell. The method may comprise or may consist of: providing the miRNA and an Ago-2 or a variant thereof; mixing the miRNA with the Ago-2 or the variant thereof; and contacting the cell with the mixture of the miRNA and the Ago-2 or the variant thereof, thereby delivering the mRNA to the cell. In various embodiments, the miRNA and the Ago-2 or the variant thereof form a ribonucleoprotein complex in the mixture.

"Various embodiments of the present invention provide a method of inhibiting or suppressing angiogenesis in a subject. The method may comprise or may consist of: providing a
miRNA and an Argonaute-2 (Ago-2) or a variant thereof; administering a therapeutically
effective amount of the miRNA and the Ago-2 or the variant thereof to the subject, thereby
inhibiting or suppressing angiogenesis in the subject. In some embodiments, the miRNA and the
Ago-2 or the variant thereof are provided in one composition. In other embodiments, the
miRNA and the Ago-2 or the variant thereof are provided in separate compositions. Various
embodiments of the present invention provide a kit for inhibiting or suppressing angiogenesis.
The kit may comprise or may consist of a quantity of a miRNA; a quantity of an Argonaute-2
(Ago-2) or a variant thereof; and instructions for using the miRNA and the Ago-2 or the variant
thereof to inhibit or suppress angiogenesis. In some embodiment, the miRNA is capable of
inhibiting or suppressing angiogenesis.

"Various embodiments of the present invention provide a method of inhibiting or
suppressing angiogenesis in a subject. The method may comprise or may consist of: providing a
miRNA and an Ago-2 or a variant thereof; mixing the miRNA with the Ago-2 or the variant
thereof; and administering a therapeutically effective amount of the mixture to the subject,
thereby inhibiting or suppressing angiogenesis in the subject. In various embodiments, the
miRNA and the Ago-2 or the variant thereof form a ribonucleoprotein complex in the mixture.
In some embodiment, the miRNA is capable of inhibiting or suppressing angiogenesis.

"Various embodiments of the present invention provide a method of promoting
angiogenesis in a subject. The method may comprise or may consist of: providing a miRNA and
an Argonaute-2 (Ago-2) or a variant thereof; administering a therapeutically effective amount of
the miRNA and the Ago-2 or the variant thereof to the subject, thereby promoting angiogenesis
in the subject. In some embodiments, the miRNA and the Ago-2 or the variant thereof are
provided in one composition. In other embodiments, the miRNA and the Ago-2 or the variant
thereof are provided in separate compositions. Various embodiments of the present invention
provide a kit for promoting angiogenesis. The kit may comprise or may consist of a quantity of a
miRNA; a quantity of an Argonaute-2 (Ago-2) or a variant thereof; and instructions for using
the miRNA and the Ago-2 or the variant thereof to promote angiogenesis. In some
embodiments, the miRNA is capable of promoting angiogenesis.

"Various embodiments of the present invention provide a method of promoting
angiogenesis in a subject. The method may comprise or may consist of: providing a miRNA and
an Ago-2 or a variant thereof; mixing the miRNA with the Ago-2 or the variant thereof; and
administering a therapeutically effective amount of the mixture to the subject, thereby
promoting angiogenesis in the subject. In various embodiments, the miRNA and the Ago-2 or
the variant thereof form a ribonucleoprotein complex in the mixture. In some embodiments, the
miRNA is capable of promoting angiogenesis.

"Various embodiments of the present invention provide a method of treating,
preventing, reducing the likelihood of having, reducing the severity of and/or slowing the
progression of a condition in a subject. The method may comprise or may consist of: providing a
miRNA and an Argonaute-2 (Ago-2) or a variant thereof; administering a therapeutically
effective amount of the miRNA and the Ago-2 or the variant thereof to the subject, thereby of
treating, preventing, reducing the likelihood of having, reducing the severity of and/or slowing
the progression of a condition in the subject. In some embodiments, the miRNA and the Ago-2
or the variant thereof are provided in one composition. In other embodiments, the miRNA and
the Ago-2 or the variant thereof are provided in separate compositions. Various embodiments of
the present invention provide a kit for treating, preventing, reducing the likelihood of having,
reducing the severity of and/or slowing the progression of a condition. The kit may comprise or
may consist of a quantity of a miRNA; a quantity of an Argonaute-2 (Ago-2) or a variant
thereof; and instructions for using the miRNA and the Ago-2 or the variant thereof to treat,
prevent, reduce the likelihood of having, reduce the severity of and/or slow the progression of
“Various embodiments of the present invention provide a method of treating, preventing, reducing the likelihood of having, reducing the severity of and/or slowing the progression of a condition in a subject. The method may comprise or may consist of: providing a miRNA and an Ago-2 or a variant thereof; mixing the miRNA and the Ago-2 or the variant thereof; and administering a therapeutically effective amount of the mixture to the subject, thereby treating, preventing, reducing the likelihood of having, reducing the severity of and/or slowing the progression of the condition in the subject. In various embodiments, the miRNA and the Ago-2 or the variant thereof form a ribonucleoprotein complex in the mixture.

In one embodiment, the miRNA and the Ago-2 or the variant thereof may be provided in one composition. In another embodiment, the miRNA and the Ago-2 or the variant thereof may be provided in two separate compositions. In various embodiments, the miRNA is administered at about 0.001 to 0.01, 0.01 to 0.1, 0.1 to 0.5, 0.5 to 5, 5 to 10, 10 to 20, 20 to 50, 50 to 100, 100 to 200, 200 to 300, 300 to 400, 400 to 500, 500 to 600, 600 to 700, 700 to 800, 800 to 900, or 900 to 1000 nmol/L. In various embodiments, the miRNA is administered intratumorally, intracranially, intraventricularly, epidurally, intradurally, intravascularly, intravenously, intraarterially, intramuscularly, subcutaneously, intraperitoneally, intranasally, or orally. In various embodiments, the mixture is administered once, twice, three or more times. In various embodiments, the mixture is administered 1-3 times per day, 1-7 times per week, or 1-9 times per month. In various embodiments, the mixture is administered for about 1-10 days, 10-20 days, 20-30 days, 30-40 days, 40-50 days, 50-60 days, 60-70 days, 70-80 days, 80-90 days, 90-100 days, 1-6 months, 6-12 months, or 1-5 years. In various embodiments, the Ago-2 or the variant thereof is administered at about 0.001 to 0.01, 0.01 to 0.1, 0.1 to 0.5, 0.5 to 5, 5 to 10, 10 to 20, 20 to 50, 50 to 100, 100 to 200, 200 to 300, 300 to 400, 400 to 500, 500 to 600, 600 to 700, 700 to 800, 800 to 900, or 900 to 1000 nmol/L. In various embodiments, the Ago-2 or the variant thereof is administered intratumorally, intracranially, intraventricularly, epidurally, intradurally, intravascularly, intravenously, intraarterially, intramuscularly, subcutaneously, intraperitoneally, intranasally, or orally. In various embodiments, the Ago-2 or the variant thereof is administered once, twice, three or more times. In various embodiments, the Ago-2 or the variant thereof is administered 1-3 times per day, 1-7 times per week, or 1-9 times per month. In various embodiments, the Ago-2 or the variant thereof is administered for about 1-10 days, 10-20 days, 20-30 days, 30-40 days, 40-50 days, 50-60 days, 60-70 days, 70-80 days, 80-90 days, 90-100 days, 1-6 months, 6-12 months, or 1-5 years.

Various methods described herein may further comprise providing and administering a therapeutically effective amount of an anti-angiogenic drug to the subject. Various kits described herein may further comprise a quantity of an anti-angiogenic drug. Various methods described herein may further comprise providing and administering a therapeutically effective amount of a chemotherapeutic agent to the subject. Various kits described herein may further comprise a quantity of a chemotherapeutic agent. Various embodiments of the present invention provide a composition. The composition may comprise or may consist of a miRNA and an Ago-2 or a variant thereof. In accordance with the present invention, the composition may be used for delivering the miRNA to a cell, inhibiting angiogenesis, promoting angiogenesis, and/or treating, preventing, reducing the likelihood of having, reducing the severity of and/or slowing the progression of a condition in a subject.

Various embodiments of the present invention provide a composition. The composition may comprise or may consist of a ribonucleoprotein complex of a miRNA and an Ago-2 or a variant thereof. In accordance with the present invention, the composition may be
used for delivering the miRNA to a cell, inhibiting angiogenesis, promoting angiogenesis and/or treating, preventing, reducing the likelihood of having, reducing the severity of and/or slowing the progression of a condition in a subject.

"In various embodiments, the subject is a human. In various embodiments, the miRNA is miR-18a or miR-128a. In some embodiment, the miRNA is capable of inhibiting or suppressing angiogenesis (e.g., miR-92, miR-92a, miR-221/22). In other embodiment, the miRNA is capable of promoting angiogenesis (e.g., miR-296, miR-126, mir-210, miR-130).

"Various compositions described herein may be formulated for intratumoral, intracranial, intraventricular, intrathecal, epidural, intradural, intravascular, intravenous, intramuscular, subcutaneous, intraperitoneal, intranasal, or oral administration. Various compositions described herein may further comprise an anti-angiogenic drug. Various compositions described herein may further comprise a chemotherapeutic agent. Various compositions described herein may further comprise a pharmaceutically acceptable excipient. Various compositions described herein may further comprise a pharmaceutically acceptable carrier.

"In accordance with the present invention, examples of anti-angiogenic drugs include but are not limited to Genentech/Roche (Bevacizumab/Avastin.RTM.), Bayer and Onyx Pharmaceuticals (sorafenib/Nexavar.RTM.), Pfizer (sunitib/Sutent.RTM.), GlaxoSmithKline (pazopanib/Votrient.RTM.), Novartis (everolimus/Affinitor.RTM.), Celgene (pomalidomide/Pomalyst.RTM.) and Ipsen and Active Biotech (tasquinimod/ABR-215050, CID 54682876).

"In accordance with the present invention, examples of the chemotherapeutic agent include but are not limited to Temozolomide, Actinomycin, Alitretinoin, All-trans retinoic acid, Azacitidine, Azathioprine, Bevacizumab, Bexatotene, Bleomycin, Bortezomib, Carboplatin, Capecitabine, Cetuximab, Cisplatin, Chlorambucil, Cyclophosphamide, Cytarabine, Daunorubicin, Docetaxel, Doxifuridine, Doxorubicin, Epirubicin, Eptothilone, Erlotinib, Etoposide, Fluorouracil, Gefitinib, Gemcitabine, Hydroxyurea, Idarubicin, Imatinib, Iplilimumab, Irinotecan, Mechlorethamine, Melphalan, Mercaptopurine, Methotrexate, Mitoxantrone, Ocresizumab, Ofatumumab, Oxaliplatin, Paclitaxel, Paniutumab, Pemetrexed, Rituximab, Tafelposide, Teniposide, Tioguanine, Topotecan, Tretinoin, Valrubicin, Vemurafenib, Vinblastine, Vincristine, Vinbeside, Vinorelbine, Vorinostat, Romidepsin, 5-fluorouracil (5-FU), 6-mercaptopurine (6-MP), Cladribine, Clorafarine, Flouxuridine, Fludarbine, Pentostatin, Mitomycin, ixabepilone, Estramustine, prednisone, methylprednisolone, dexamethasone or a combination thereof.

"Various compositions, methods and kits of the present invention find utility in the treatment of various conditions, including but not limited to neurovascular disease, brain vascular disease, cerebra arteriovenous malformation (AMV), stroke, tumor or cancer, brain tumor, glioma, glioblastoma, and glioblastoma multiform (GBM).

BRIEF DESCRIPTION OF THE DRAWINGS

"Exemplary embodiments are illustrated in referenced figures. It is intended that the embodiments and figures disclosed herein are to be considered illustrative rather than restrictive.

"FIG. 1 shows, in accordance with various embodiments of the invention, that AVM-BEC-conditioned media (AVM-BEC-CM) potentiates miR-18a internalization. A) AVM-BEC and control BEC were analyzed for intracellular miR-18a levels using qPCR. Control BEC were used as baseline (n=3; p<0.01). B) miR-18a (40 nmol/L) in combination with AVM-BEC-CM (black bars) or fresh culture media (white bars) was added to AVM-BEC and tested for intracellular miR-18a after 5, 10, 30 minutes, and 24 hours. AVM-BEC-CM enhanced miR-18a
entry up to 30 minutes (n=3-4; *p<0.05; p<0.01). C) Control BEC were treated with miR-18a (40 nmol/L) in combination with AVM-BEC-CM (black bar), control BEC-CM (gray bar) or fresh media (white bar). Intracellular miR-18a was analyzed (qPCR) after 30 minutes incubation; AVM-BEC-CM potentiated miR-18a internalization by control BEC (n=3; p<0.01). D) Control BEC were treated with miR-18a (40 nmol/L) and in the presence of serial diluted AVM-BEC-CM (diagonal line bars), demonstrating that progressively diluted AVM-BEC-CM loses its ability to enhance miR-18a internalization (n=3, p<0.01, p<0.001). Dotted line represents miR-18a uptake by control BEC in the presence of fresh media.

"FIG. 2 shows, in accordance with various embodiments of the invention, that Ago-2 is highly expressed by AVM-BEC. A) Basal expression of RNA-binding proteins (NPM, nucleophosmin-1; NCL, nucleolin; Ago-2, argonaute-2) in AVM-BEC and control BEC were analyzed by qPCR. Increased levels of NCL and Ago-2 in AVM-BEC as compared to control BEC were detected (n=3; p<0.01; *p<0.001). B) AVM-BEC were treated with siAgo (30-75 nmol/L), scrambled siAgo (50-75 nmol/L) and lipofectamine (2 ug/ml) and Ago-2 protein levels were analyzed by Western blotting. siAgo-2 (75 nmol/L) decreased approximately 50% of intracellular Ago-2 protein content (n=3; *p<0.05). A representative image depicting the effects of siAgo-2 (75 nmol/L) alone and in the presence of lipofectamine (2 .mu.g/ml) is shown below."

"FIG. 3 shows, in accordance with various embodiments of the invention, that Ago-2 silencing compromises miR-18a entry. A) Intracellular miR-18a detection in AVM-BEC, control BEC, tumor-derived endothelial cells (TuBEC), human umbilical vein endothelial cells (HUVEC), human microvascular endothelial cells (HMEC) and astrocytes treated with miR-18a (40 nmol/L) in the presence of siAgo-2-AVM-BEC-CM (dotted bars) or AVM-BEC-CM (black bars). Ago-2 silencing decreased miR-18 entry in AVM-BEC, control BEC and TuBEC (n=3; *p<0.05; p<0.001). B) Intracellular detection of miR-18a in control BEC (qPCR) after treating cells for 30 minutes with different concentrations of Ago-2 (0.01-4 nmol/L) in combination with miR-18a (40 nmol/L) showed that higher concentrations of Ago-2 (up to 0.4 nmol/L) increased miR-18a detection (n=3). Dotted line represents miR-18a uptake by control BEC in the presence of AVM-BEC-CM. C) Analysis of intracellular miR-18a (qPCR) showed that miR-18a (40 nmol/L) in combination with Ago-2 (0.4 nmol/L) (for 5, 30, 120 and 1440 minutes) was more resistant to degradation than miR-18a alone; maximum effect was observed at 120 minutes (n=3; p<0.01). D) AVM-BEC and control BEC were exposed to miR-18a in combination with siAgo-2-AVM-BEC-CM or AVM-BEC-CM. Ago-2 staining (red) showed that cells exposed to AVM-BEC-CM increased Ago-2 detection in control BEC when treated with miR-18a (40 nmol/L) (n=3, p<0.01). Nuclear staining is shown in blue.

"FIG. 4 shows, in accordance with various embodiments of the invention, that facilitated transport is involved in miR-18a delivery. A) AVM-BEC and control BEC were treated with AVM-BEC-CM plus miR-18a (40 nmol/L) at 4.degree. C. and 37.degree. C. for 30 minutes. Intracellular miR-18a was measured using qPCR as described previously, showing that at 4.degree. C. miRNA entry was only minimally compromised (n=3). B) The distribution of Ago-2 (red) was identified using immunocytochemistry. At 4.degree. C. untreated AVM-BEC expressed high levels of intracellular Ago-2 (i) compared to untreated control BEC (ii). When control BEC were treated with AVM-BEC-CM plus miR-18a at 4.degree. C., Ago-2 staining was apparent and associated with the cell membrane (iii; white arrows) (n=3). Blue staining denotes nuclear staining. C) The formation of a ribonucleoprotein complex between Ago-2 and miR-18a was determined by immunoprecipitation and immunoblotting (left panel) and qPCR (right panel). Ago-2 was detected only in the two fractions in contact with anti-Ago-2, as expected. Only the fraction with both Ago-2 and miR-18, but not miR-18a alone, led to the detection of miR-18a by qPCR. Rabbit IgG served as the isotypic control.

"FIG. 5 shows, in accordance with various embodiments of the invention, that Ago-2...
silencing decreases miR-18a-induced TSP-1 secretion. A) AVM-BEC were treated with siAgo-2 (75 nM) followed by miR-18a treatment (40 nmol/L) and cell supernatants tested for TSP-1 (n=4; *p<0.05). B) Control BEC were treated with varying concentrations of the miR-18a inhibitory sequence, antagonir (40-120 nmol/L). Antagomir treatment (80 nmol/L) significantly decreased TSP-1 levels (n=4; p<0.01).

"FIG. 6 shows, in accordance with various embodiments of the invention, that Co-treatment of miR-18a and Ago-2 in vivo 'normalizes' TSP-1 and VEGF-A plasma levels. A) Athymic nude mice were implanted with glioma cells intracranially. After 3 days, animals were treated intravenously with vehicle, miR-18a plus Ago-2, miR-18a alone or Ago-2 alone every 48 hours for three cycles. Subsequently, plasma was tested for TSP-1 (A) and VEGF-A (B). miR-18a and Ago-2 combination treatment caused the most significant increase of TSP-1 levels (n=5; *p<0.05; p<0.01, ***p<0.001), and reduction of VEGF-A levels (n=5; *p<0.05). Control plasma (healthy) was obtained from normal athymic mice."

**Patents**

**Researchers Submit Patent Application, "Compositions and Methods for the Treatment and Management of Steatosis in Human Liver", for Approval (USPTO 20160367537)**

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- From Washington, D.C., NewsRx journalists report that a patent application by the inventor Rudel, Lawrence L. (Winston-Salem, NC), filed on June 18, 2014, was made available online on December 29, 2016.

No assignee for this patent application has been made.

News editors obtained the following quote from the background information supplied by the inventors: "Several publications and patent documents are cited throughout the specification in order to describe the state of the art to which this invention pertains. Each of these references are incorporated herein as though set forth in full.

"Non-alcoholic fatty liver disease (NAFLD) has emerged as an epidemic in the United States and other industrialized countries.(1) Abnormal fat deposition in the liver worsens patient response to viral hepatitis therapy and steatosis has a significant rate of transition to cirrhosis and hepatocellular carcinoma.(2-4) It is estimated that one third of Americans have fatty liver, and that NAFL will eventually supplant hepatitis C as the leading indication for liver transplant in western countries.(5) Additionally, fatty liver disease has additional human health implications, since steatosis has been linked to insulin resistance, obesity, hyperlipidemia, and atherosclerotic heart disease in humans.(6-8) NAFLD is recognized as the main cause of hepatic
steatosis, one of the more common liver disorders in the general population.

"Studies have identified a number of genetic determinants of hepatic steatosis, which include mutations in the lysosomal acid lipase (NIPA) gene. Such mutations are recognized as contributing factors to the pathogenesis of cholesterol ester storage disease and Wolman disease. Both of these disease states are characterized by a lack of the LAL enzyme which results in massive accumulation of cholesterol ester and triglycerides in the liver, gut and other organs.

"Wolman disease, which is the early-onset form of LAL deficiency, is fatal in most instances, typically before one year of age.

"Late onset LAL deficiency, commonly referred to as cholesterol ester storage disease (CESD), may lead to cirrhosis of the liver, liver failure and death among children, adolescents and adults. Those diagnosed with CESD appear to be at an increased risk of stroke, due to atherosclerosis, i.e., the accumulation of lipids in the walls of major arteries.

"Individuals who suffer from Wolman disease and CESD frequently are undiagnosed because their symptoms are mistaken for those of more prevalent conditions, e.g., NAFLD, non-alcoholic steatohepatitis (NASH) and alcoholic liver disease.

"Currently, medical treatment for LAL deficiency disorders involve attempts at managing symptoms. Combination therapy for reducing cholesterol, together with a diet excluding food rich in cholesterol and triglycerides have been effective at reducing some symptoms of CESD. Intravenous nutritional support is sometimes used for Wolman disease patients, if bone marrow transplantation is being considered. See also, Scriver et al., The Metabolic and Molecular Bases of Inherited Disease, Vol. 2, Chap. 82 'Acid Lipase Deficiency: Wolman Disease and Cholesterol Ester Storage Disease', 2563-87 (1995).

"More recently, it has been proposed to treat LAL deficiency disorders by administering stem cells that provide lysosomal enzymes, or by enzyme replacement therapy using a human recombinant lysosomal acid lipase. See e.g., U.S. Pat. No. 7,927,587 to Blazer et al. and U.S. Pat. No.8,663,631 to Quinn. The therapeutic efficacy of such treatments, however, has yet to be established."

As a supplement to the background information on this patent application, NewsRx correspondents also obtained the inventor's summary information for this patent application: "In accordance with the present invention, a method for the treatment and or management of hepatic steatosis in a patient in need thereof is disclosed. An exemplary method entails administration of an effective amount of a steroyl-O-acyltransferase inhibitor, the inhibitor being effective to reduce cholesterol ester accumulation, thereby inhibiting or reducing symptoms associated with steatosis. In one embodiment, the inhibitor is an inhibitory nucleic acid molecule. In yet another embodiment, the inhibitor is pyripyoprene A derivative or a pharmaceutically acceptable salts, solvates or hydrates thereof. In yet another embodiment, the SOAT2 inhibitor is delivered in an amount effective to inhibit cholesterol ester accumulation in the liver of such patients.

BRIEF DESCRIPTION OF THE DRAWINGS

"FIG. 1 is a panel of bar graphs showing that the major lipid class present in liver of all clinical groups was triglyceride, and it appeared to systematically increase among the study groups with the highest average being found in the obese, NASH group.

"FIG. 2 is series of graphs showing the systematic increases among study groups in the two neutral lipid classes suggesting that mechanisms leading to accumulation of these lipids may be associated.

"FIG. 3 is a series of bar graphs showing the results of analysis of the acyl compositions of hepatic triglycerides and cholesterol esters as compared to the same lipid
classes in plasma.

"FIG. 4 is a series of bar graphs showing that the percentages of CEFA in the liver compared to those percentages in plasma across all study groups by paired t-test were higher in saturated and monounsaturated fatty acids which presumably represents the contribution made by the tissue SOAT2 enzyme.

"FIGS. 5A-5D are a series of tables showing unesterified and esterified cholesterol concentrations and contents in the liver, small intestine and spleen in LAL.sup.-/- mice given the SOAT2 inhibitor, PRD-125 from 21 to 52 or 53 days of age."

Patents

Researchers Submit Patent Application, "Immunogenic Compositions", for Approval (USPTO 20160367655)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- From Washington, D.C., NewsRx journalists report that a patent application by the inventors Gallichan, Scott (Burlington, CA); Mancevski, Ausra (Toronto, CA); Reveneau, Nathalie (Toronto, CA); Su, Jin (Markham, CA); Dalencon, Francois (Lyon, FR); Haensler, Jean (Grezieu-la-Varrene, FR), filed on March 21, 2016, was made available online on December 29, 2016.

No assignee for this patent application has been made.

News editors obtained the following quote from the background information supplied by the inventors: "This invention relates to the field of immunogenic compositions which comprise an adjuvant. More particularly, the invention relates to adjuvanted immunogenic compositions (e.g., vaccines) against at least one or more Chlamydia species.

"Chlamydia bacteria are obligate intracellular pathogens of eukaryotic cells. Three species of the family Chlamydia infect humans--C. trachomatis, C. pneumoniae, and C. psittaci--and genomic sequences for each of these are publicly available.

"C. trachomatis organisms are dimorphic, and alternate between two distinct morphological forms, the infectious elementary bodies (EB) and the metabolically active reticulate bodies (RB) The EBs infect eukaryotic cells; they are endocytosed by mucosal cells into vesicular inclusions and are transformed into RB. Within the inclusion, the RBs replicate and redifferentiate into EBs before being released through cell lysis to infect neighbouring cells.

"Chlamydia trachomatis is the most prevalent sexually transmitted bacterial pathogen in the world, with an estimated 100 million clinically diagnosed cases occurring annually. In
addition, a similar or greater number of asymptomatic cases go undetected. The most common clinical presentations are urethritis and cervicitis. These acute manifestations typically resolve over a period of a few weeks. However, in certain patients, long-term sequelae may develop, including pelvic inflammatory disease, ectopic pregnancy, and infertility. In areas of the world with poor hygienic conditions, Chlamydia trachomatis causes trachoma and lymphogranuloma venerum (LGV). Although effective antibiotic therapy is available, eradication of these organisms will most likely only be achieved through a vaccination program. To date, no vaccine is commercially available against this infection.

"Compositions including the major outer membrane protein (referenced herein as 'MOMP') of Chlamydia trachomatis are known. In particular, the article entitled, 'Vaccination with the Chlamydia trachomatis Major Outer Membrane Protein Can Elicit an Immune Response as Protective as That Resulting from Inoculation with Live Bacteria', Sukumar Pal et. al., Infection and Immunity, December 2005, p. 8153-8160 discloses the use of Chlamydia antigens in conjunction with adjuvants in an immunization composition. The publication discloses studies using the adjuvants CpG+alum, or CpG+Montanide ISA 720. According to the authors of this publication, the results obtained with these adjuvants were quite encouraging, but still required improvement. Moreover, while these adjuvants are quite suitable for animals, their ability to be used in humans is uncertain. Indeed, CpG oligonucleotides have been known to perform well in animals, but not so well in humans and Montanide ISA 720, a water-in-oil emulsion, can be rather painful when administered to humans.

"Therefore, there still remains a need for a safe and effective immunogenic composition against Chlamydial infections." As a supplement to the background information on this patent application, NewsRx correspondents also obtained the inventors' summary information for this patent application:

"The present invention provides compositions such as immunogenic compositions (e.g., vaccine compositions), comprising a Chlamydial major outer membrane protein (referenced herein as 'MOMP') from at least one Chlamydial serovar, and an adjuvant, characterized in that the adjuvant comprises at least the product E6020 having CAS Registry Number 287180-63-6. In these embodiments, the adjuvant may further comprise at least one carrier system (such as e.g., emulsion, mineral particle).

"The MOMP protein may be derived from any species of Chlamydia (e.g., C. trachomatis, C. pneumoniae, C. psittaci, or C. trachomatis MoPn). In preferred embodiments, the composition comprises one or more major outer membrane proteins each derived from different serovars of C. trachomatis The invention also provides methods of inducing an immune response to a Chlamydia species (e.g., C. trachomatis) in a subject, by administering to the subject a composition of the invention.

"In one example the Chlamydial major outer membrane protein is derived from any species of Chlamydia (e.g. C. trachomatis, C. pneumoniae, C. psittaci, or C. trachomatis mouse pneumonitis (MoPn)). In preferred embodiments, the major outer membrane protein is derived from C. trachomatis. In a preferred embodiment, the composition includes two, three, four or more (e.g., five) Chlamydial major membrane proteins each derived from a different serovar of C. trachomatis.

"According to an embodiment of the present invention, the composition also comprises a carrier system which may assist in the delivery of the antigen and/or the product E6020, or which may increase the adjuvant effect of E6020.

"This carrier system can comprise a suspension of aluminum salts, such as aluminum hydroxide, aluminum phosphate, aluminum hydroxyphosphate, or a mixture of them. In preferred embodiments, aluminum hydroxide is included.
"According to an embodiment, the carrier may comprise an emulsion, and particularly an oil-in-water emulsion.

"According to a further embodiment of the present invention, the composition also comprises an immunostimulant such as a Toll-like Receptor 7/8 agonist, and particularly an imidazoquinoline product.

"The compositions can be in liquid form, dry powder form, freeze dried, spray dried or foam dried.

"Specific examples of the compositions of the invention include those set out in the examples herein such as for example, the Adjuvants of the invention, ADJ.A, and ADJ.B.

"The invention also provides a method of making compositions comprising at least one recombinant Chlamydial MOMP, and an adjuvant, characterized in that the adjuvant comprises at least product E6020 having CAS Number 287180-63-6.

"The method includes providing at least one Chlamydial MOMP and admixing the at least one recombinant MOMP with an adjuvant, the adjuvant comprising at least product E6020 having CAS Number 287180-63-6.

"The invention also provides methods of inducing an immune response to a Chlamydia species (e.g., C. trachomatis) in a subject, which involve administering to the subject a composition as described herein. In addition, the invention includes use of the compositions of the invention in inducing an immune response to Chlamydia species (e.g., C. trachomatis).

"The invention provides a number of advantages. For example, in addition to being safe for human use, the immunogenic composition of the present invention provides an immune response which is both significant and Th1 oriented or Th1/Th2 balanced and therefore, favorable for a Chlamydia vaccine. Other features and advantages of the invention will be apparent from the following Detailed Description, the Drawings, and the Claims.

BRIEF DESCRIPTION OF THE DRAWINGS

"FIG. 1: shows a representative Blue Native PAGE gel analysis of rMOMP (serovar E, C. trachomatis) protein samples: two pilot scale samples (left, A,B) and three lab scale samples (right, C--H)

"FIG. 2: shows a representative SDS-PAGE gel of rMOMP (serovar E, C. trachomatis) pilot scale (JR3182) protein samples demonstrating the structure of the rMOMP protein at various steps (i.e., samples of the solubilized IBs, the purified denatured MOMP (Q pool), the folded protein, and the final product)"

Researchers Submit Patent Application, "Lipid Nanodiscs and Nanorods as Modulators of Clotting Factor Function in Vivo", for Approval (USPTO 20160367677)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- From Washington, D.C., NewsRx journalists report that a patent application by the inventor Stoilova-McPhie, Svetla (Dallas, TX), filed on June 17, 2016, was made available online on December 29, 2016.

The patent's assignee is Board of Regents, The University of Texas System.

News editors obtained the following quote from the background information supplied by the inventors: "Without limiting the scope of the invention, its background is described in connection with blood clotting.

"Factor VIII in its active form serves as the co-factor to the serine protease Factor IXa within the membrane-bound intrinsic tenase complex. The assembly of the FVIIIa-FIXa complex on the activated platelet surface increases FIXa proteolytic activity and Factor Xa generation more than 100,000 times, which is critical for normal hemostasis (1, 2). FVIII is a heterodimer composed of a variable length heavy chain (HC: A1-A2-B) of 90-200 kDa containing variable length B-domain and a constant length light chain (LC: A3-C1-C2) of 80 kDa. The LC and HC are non-covalently linked via divalent Ca.sup.2+ ion(s) (1). Factor VIII is activated by Thrombin resulting in the cleavage of the entire B domain and separation of the A2 and A1 domains (3). Activated FVIII (FVIIIa) is a heterotrimer composed of non-covalently linked A1, A2 domains and the LC. The A1 and LC retain the metal ion-dependent linkage through the A1-A3 domains, whereas the association of A2 to A1 is mediated solely by hydrophobic and electrostatic interactions (1, 2, 4-10). The A2 and A3 domains contain the main protease (FIXa) binding sites and the C domains hold the main membrane binding sites (11-13). The FVIIIa binds to the FIXa with high affinity in a membrane-dependent manner resulting in the intrinsic tenase (FVIIIa-FIXa) complex assembly on the activated platelet surface during the propagation phase of critical for sufficient Thrombin generation (1, 14, 15).

"Defect or deficiency of FVIII is cause for Hemophilia A, and Hemophilia A is effectively corrected by repetitive intravenous injection of recombinant or plasma-derived FVIII concentrates to prevent recurring bleeding (16). Despite the critical role of FVIII for normal hemostasis the knowledge of its membrane-bound organization alone or within the intrinsic tenase complex is incomplete, due to the complexity of its domain organization and instability of the active form--FVIIIa. This lack of structural information hampers drug discovery that can effectively regulate the activity of the intrinsic tenase complex and improve the design of new pro- and anti-coagulant drugs.

"In the last decade a new approach for functional and structural studies of membrane-associated proteins was developed based on lipid nanodiscs (ND) technologies that can mimic the lipid composition of physiological membranes. Lipid ND have been previously employed for functional assays of coagulation factors and complexes, such as the Tissue Factor-Factor VIIa complexes and showed the advantage of this approach over phospholipid vesicles and artificial membrane bilayers in terms of precise control of the local membrane composition that surrounds the coagulation complexes (17). ND are small, about 10 nm in diameter size circular lipid bilayer membrane patches stabilized by two molecules of amphiphilic membrane scaffolding proteins (MSP). They are produced by a self-assembly process, which creates a preparation of homogenous and highly stable lipid bilayer discs with controlled lipid
composition. Such small size of the available membrane surface can allow the assembly of macromolecular complexes that contain the protein molecules of interest attached to the ND membrane with a size and macromolecular mass suitable for visualization and structure determination by single particle EM (18). The geometry (flat membrane discs) and homogenous distribution of the ND makes them more desirable for structural studies than liposomes, which are more heterogeneous in size with a higher curvature and larger membrane surface that leads to overlap membrane-bound molecules in the EM images (19).

As a supplement to the background information on this patent application, NewsRx correspondents also obtained the inventor's summary information for this patent application: "In another embodiment, the present invention includes a lipid nanodisk or nanotube composition comprising: a lipid composition comprising phosphatidylserine and galactosylceramide and a membrane-bound Factor VIII protein, a membrane-bound Factor IX protein, a membrane-bound Factor VIII-Factor IX protein complex, or a membrane-bound Factor V and Factor X proteins and their complex in or about the lipid nanodisks or nanotubes. In one aspect, the membrane-bound Factor VIII is a full length or B-domain deleted variant of recombinant FVIII. In another aspect, the phosphatidylserine and galactosylceramide lipids and any derived lipids are at a ratio from 20 to 80 percent by volume. In another aspect, the phosphatidylserine is used as a 20 to 50%, or 50 to 80% liquid composition. In another aspect, the membrane-bound Factor VIII to lipid ratio is from 1:47 to 1:72. In another aspect, the membrane-bound Factor VIII to lipid ratio is from 1:40 to 1:150. In another aspect, the nanodisk is in a phosphatidylserine 80% lipid composition and 1:47 membrane-bound Factor VIII to lipid ratio. In another aspect, the composition further comprises one or more amphiphilic membrane scaffolding proteins (MSP) and/or their derivatives of Apolipoproteins I. In another aspect, the Factor VIII protein, the Factor IX protein, the Factor VIII-Factor IX protein complex, or the Factor V, Factor X proteins and their complex is an activated form of the protein. In another aspect, the Factor VIII is activated truncated protein that forms a functional intrinsic tenase complex with a human FIXa on a negatively charged phospholipid surface.

"Another embodiment of the present invention includes a method of making a lipid nanodisk or nanotube comprising: dissolving phosphatidylserine and galactosylceramide lipids in an organic solvent; evaporating the organic solvent under a noble gas, reconstituting the lipids in an aqueous buffered solution with Na cholate, warming and sonicating the lipids until they are in solution, adding a membrane-bound Factor VIII protein, a membrane-bound Factor IX protein, a membrane-bound Factor VIII-Factor IX protein complex, or a membrane-bound Factor V and Factor X proteins and their complex into the lipids, and removing the Na Cholate with beads, wherein the NaCholate-beads that are removed by centrifugation. In one aspect, the membrane-bound Factor VIII is a full-length or a B-domain deleted variant of recombinant FVIII. In another aspect, the phosphatidylserine and galactosylceramide lipids and any derived lipids are at a ratio from 20 to 80 percent by volume. In another aspect, the phosphatidylserine is used as a 20 to 50%, or 50 to 80% liquid composition. In another aspect, the membrane-bound Factor VIII to lipid ratio is from 1:47 to 1:72. In another aspect, the membrane-bound Factor VIII to lipid ratio is from 1:40 to 1:150. In another aspect, the nanodisk is in a phosphatidylserine 80% lipid composition and 1:47 membrane-bound Factor VIII to lipid ratio. In another aspect, the composition further comprises one or more amphiphilic membrane scaffolding proteins (MSP) and/or their derivatives of Apolipoproteins I. In another aspect, the Factor VIII protein, the Factor IX protein, the Factor VIII-Factor IX protein complex, or the Factor V, Factor X proteins and their complex is an activated form of the protein. In another aspect, the Factor VIII is activated truncated protein that forms a functional intrinsic tenase complex with a human FIXa on a negatively charged phospholipid surface.

"Yet another embodiment includes a method of treating a disease of blood
coagulation comprising: identifying a subject in need of treatment for the disease of blood coagulation caused by a mutation in at least one of Factor V, Factor VIII, Factor IX, or Factor X; and providing the subject with a therapeutically effective amount of a phosphatidylerine and galactosylceramide nanodisk or nanotube composition comprising a membrane-bound Factor VIII protein, a membrane-bound Factor IX protein, a membrane-bound Factor VIII-Factor IX protein complex, or a membrane-bound Factor V and Factor X proteins complex, wherein the Factor V, Factor VIII, Factor IX, or Factor X are provided in an active or inactive form.

"Yet another embodiment includes a method of determining the effectiveness of a candidate drug that impacts Factor V, VIII, IX and/or X activity, the method comprising: (a) obtaining a serum or plasma from a normal subject and a subject with an abnormality in blood clotting; (b) preparing a stable lipid nanodisk or nanotube comprising phosphatidylerine and galactosylceramide that comprises at least one of: a membrane-bound Factor VIII protein, a membrane-bound Factor IX protein, a membrane-bound Factor VIII-Factor IX protein complex, or a membrane-bound Factor V-Factor X protein complex; (c) combining the serum or plasma from the normal and from the abnormal subjects; and (d) imaging the membrane-bound Factor VIII protein, the membrane-bound Factor IX protein, the membrane-bound FactorVIII-Factor IX protein, or the membrane-bound Factor VIII-Factor IX protein complex in the normal and the abnormal serum by at least one of electron microscopy or single-particle analysis; (e) adding the candidate drug to the nanodisks or nanotubes, and (f) imaging the nanodisks or nanotubes in the normal and the abnormal serum by at least one of electron microscopy or single-particle analysis to determine the structural differences in nanodisks or nanotubes comprising the membrane-bound Factor VIII protein, the membrane-bound Factor IX protein, the membrane-bound FactorVIII-Factor IX protein, or the membrane-bound Factor VIII-Factor IX protein complex in the presence or absence of the candidate drug.

"The present invention also includes compositions and methods for making a stable Factor VIII-Nanodisk (FVIII-ND) complexes suitable for structural studies by EM and single-particle analysis. The FVIII-ND of the present invention is a B-domain deleted recombinant porcine FVIII, which has a 84% sequence identity with the human FVIII analogue and is used as a drug for Hemophilia A in patients who develop antibodies against human FVIII (24, 25). Recombinant porcine FVIII lacking the B-domain has much higher expression level in cell culture than the human FVIII analogue, has a higher stability in its activated form and forms functional intrinsic tenase complexes with human FIXa on negatively charged phospholipid surface, which makes it an ideal candidate for structural and functional studies by EM at close to physiological conditions (26-28). To achieve a homogenous population of functional FVIII molecules bound to the PS-rich ND, the ND were first assembled at different PS concentration and MSP1D1 to lipid ratio. The ND population that was the most amenable for single particle analysis of the negatively stained FVIII-ND complexes adsorbed on amorphous carbon film was selected. The calculated FVIII membrane-bound organization at 25 Ångstrom resolution showed that FVIII organizes preferentially as a dimer at the ND surface on both or one side of the ND. This organization confirms the inventor's previous analysis for human and porcine FVIII helically organized on lipid nanotubes (LNT) with the same lipid composition (29, 30). The developed algorithm for monitoring the FVIII membrane-bound organization, as bound to ND is a significant step towards resolving the FVIIIa-FIXa functional organization on the activated platelet membrane. The lipid nanotechnologies employed in this study were also tested for their stability to stabilize active coagulation complexes in vivo.

BRIEF DESCRIPTION OF THE DRAWINGS

"For a more complete understanding of the features and advantages of the present invention, reference is now made to the detailed description of the invention along with the
accompanying figures and in which:

"FIGS. 1A to 1E are graphs that summarize the data obtained from electron microscope photographs of nanodisks (ND) at different lipid composition. Electron micrographs of negatively stained GC-based ND containing the following ratios of phosphatidylserine (PS) and galactosylceramide and a membrane scaffolding protein (MSP), in this case membrane scaffolding protein 1D1 (MSP1D1) (Sigma-Aldrich), are summarized in the following graphs: FIG. 1A) 80% PS, 1:72 MSP1D1 to lipids ratio; FIG. 1B) 80% PS, 1:47 MSP1D1 to lipids ratio; FIG. 1C) 50% PS, 1:47 MSP1D1 to lipids ratio, fraction I; FIG. 1D) 50% PS, 1:47 MSP1D1 to lipids ratio, fraction II; FIG. 1E) 20% PS, 1:47 MSP1D1 to lipids ratio. The graphs show the size distribution of the ND with different lipid composition, as characterized by direct measurements from the EM images of about 200 ND particles diameter. The ND particles with different diameter are separated in four groups and color-coded as follows: white <10 nm diameter, grey between 10.0 and 14.0 nm diameter, dark grey between 14 and 18 nm and black >18 nm. The average diameter and standard deviation are shown for each ND population. Representative class averages (2D class averages of ND particles with similar diameter, as classified by similarity in shape and density/mass distribution by the reference free 2D classification algorithms implemented in EMAN2 (34)) are shown under the graphs.

"FIGS. 2A to 2D are graphs that show size exclusion chromatography (SEC) elution profiles and dynamic light scattering (DLS) measurements of the ND at different PS compositions and MPS1D1 to lipids ratio. On the left are the elution profiles of the ND, as obtained from the FPLC. The scale at the bottom of the elution profiles show the diameters (d) of the particles in nm, as calibrated from the elution times of standard proteins with known Stokes radii: thyroglobulin, 8.5 nm; ferritin, 6.1 nm; bovine liver catalase, 5.2 nm; bovine serum albumin, 3.55 nm. On the right are shown the DLS particles distribution from the pooled FPLC fractions. The mean hydrodynamic radius (r) of the ND particles is shown in nm and their polydispersity, as a standard deviation (SD). The mass distribution of each ND population is shown as a percentage of the total mass of particles (y-axis, %). FIG. 2A: phosphatidylserine (PS) 80%, 1:72 MSP1D1 to lipids ratio; FIG. 2B: PS 80%, 1:47 MSP1D1 to lipids ratio; FIG. 2C: PS 50%, 1:47 MSP1D1 to lipids ratio. Two separate populations of ND were pooled into fraction I and fraction II and the DLS measurements were carried out separately for fraction I and fraction II. FIG. 2D: PS 20%, 1:47 MSP1D1 to lipids ratio.

"FIG. 3 is a graph that shows data digitized and the area measure with the UCSF Chimera software suite for image visualization and analysis. No Treatment, Nanodisks-(ND), pFVIII, pFVIII-ND. 1=30 seconds, 40=20 minutes.

"FIG. 4A is a graph that shows the averaged results shown on in FIG. 3 with the STDEV plotted to one side.

"FIG. 4B is a graph that shows the average total volume per condition (over 20 minutes) as shown on FIG. 4A. No treatment, -ND, -pFVIII, -pFVIII-ND. 1=30 seconds, 40=20 minutes.

"FIG. 5 is graph that shows the results of an anti-FVIII ELISA titer of rpFVIII (circles) and rpFVIIIND (squares). FVIII deficient mice were injected every 7 days with 2 .mu.g/mouse recombinant porcine FVIII alone or porcine FVIII-ND complex. Each mouse received 4 doses, and plasma was obtained one week after the final dose. Serial dilutions (1:2) of plasma were added to ELISA plates coated with porcine or human FVIII, and the highest plasma dilution that produced a reading of .gt;eq.0.2 OD over background at 450 nm were reported as endpoint titers.

"FIG. 6 shows a far UV-CD spectra and secondary structure deconvolution of MSP1D1 alone and when assembled in ND at different lipid composition.
"FIGS. 7A and 7B are EM micrographs of negatively stained Y branched and side-attached nanodisk (ND) stacks adsorbed on amorphous carbon assembled at MSP1E3D1 to lipids ratio of 1:150 after 60 minutes incubation with 10 mM CaCl.sub.2. The inset shows double and triple ND stacks formed bellow 5 mM CaCl2. Scale bar is 10 nm. The protein-lipid densities are in white. FIG. 7B. Cryo-EM micrographs of the ND stacks in amorphous ice (vitreous water) after 60 minutes incubation with 10 mM CaCl.sub.2. The protein-lipid densities are in black.

"FIG. 8. Electron micrographs of negatively stained ND and FVIII-ND complexe on amorphous carbon. The insets show magnified views of the square areas. Scale bar is 10 nm. Representative 2D class averages from selected ND and FVIII-ND particles boxed at 180.times.180 pixels at 2.9 .ANG./pix and masked with a radial mask.

"FIGS. 9A and 9B show the activity of FVIII in solution and bound to nanotubes (LNT) and ND containing 80% PS and scaffolding protein (MSP1D1) to lipid of 1:47 as measured by the activated partial thromboplastin time (aPTT) assay against FVIII deficient human plasma. FIG. 9A. Standard curve for Factor Assay Control plasma (FACT) containing 1 U/ml human FVIII. FIG. 9B. Activities of human and porcine FVIII in solution and when bound to LNT and ND. The LNT and ND were mixed in an excess of 10 times to the FVIII to secure that all FVIII molecules are in a membrane-bound state.

"FIGS. 10A and 10B are Cryo-EM micrographs (1024.times.1024 pixels @ 1.4 .ANG./pix) of porcine FVIII-LNT (FIG. 10A) and FVIIIa-LNT (FIG. 10B) helically organized on LNT. The insets show the Fourier transforms. FIG. 10C shows a SDS-PAGE of porcine FVIII and pFVIIIa, showing the trimeric nature of the FVIIIa molecule. The molecular weight of the standard proteins is in kDa.

"FIG. 11 shows the size distribution of PS-GC-ND assembled from PS:GC=4:1 ratio and two MSP: MSP1D1 and MSP1E3D1 at different MSP to lipid ratio. Left. EM micrographs of negatively stained ND adsorbed on amorphous carbon. Scale bar 50 nm. Right. Size distribution graphs as measured from the NS-EM micrographs."

Patents
Researchers Submit Patent Application, "Method and Improved Pharmaceutical Composition for Enhancing Transdermal Delivery of Pde-5 Inhibitor", for Approval (USPTO 20160367493)
Wellness Week -- From Washington, D.C., NewsRx journalists report that a patent application by the inventors LIU, Yee-Chien (New Taipei City, TW); WU, Pei-Ling (New Taipei City, TW), filed on June 16, 2016, was made available online on December 29, 2016. No assignee for this patent application has been made.

News editors obtained the following quote from the background information supplied by the inventors: "The present disclosure relates to the field of drug delivery, and more particularly to the use of an enhancer to enhance the permeation of a pharmacologically active agent through human or animal skin.

"Phosphodiesterase (PDE) is an enzyme found in various tissues. The interest in PDEs as molecular targets of drug action has grown with the development of isozyme-selective PDE inhibitors that offer potent inhibition of selected isozymes without the side-effects attributed to nonselective inhibitors. Sildenafil, vardenafil and tadalafil are inhibitors of cGMP-specific phosphodiesterase type 5 (PDE-5).

"PDE-5 inhibitors are used to treat primary pulmonary hypertension (PPH), which is a disease in which blood vessels in the lungs become abnormally narrow; and erectile dysfunction. There are now three oral formulation containing PDE-5 inhibitors for treating erectile dysfunction (ED), they are Viagra (containing sildenafil) by Pfizer, Levitra (containing vardenafil) by Bayer Pharmaceutical and Glaxo-Smith-Kline-Beecham/Schering Plough, and Cialis (containing tadalafil) by Lilly-ICOS.

"Although oral delivery is a convenient and non-invasive way of delivering a pharmacologically active compound, yet it has its own disadvantages. For example, it is slow acting, for the drug would have to go through the gastrointestinal system of the recipient before it can reach the intended target site such as penis for ED treatment. Further, it is more likely to cause a number of side-effects, for the drug will be circulated systematically instead of exerting its function locally.

"Transdermal delivery is a feasible solution to the above-identified disadvantages of oral formulation of PDE-5 inhibitors. Various substances are known to enhance the ability of drugs and agents to diffuse through the skin and other tissues. The more popular approach has been the employment of surface active agents. However, many surface active agents enhance the permeability by actually damaging the barrier tissue. Only slight to moderate enhancement of penetration is effected with the prior art surface active agents. Another approach is to use certain organic solvents, such as dimethylsulfoxide (DMSO), dimethyl formamide (DMF) or N,N-dimethylacetamide, to enhance the penetration of active substances through stratum corneum. A disadvantage of using these solvents is that they are systemically distributed in a short period of time and cause undesirable side effects.

"Thus, it would be desirable to provide an improved transdermal formulation that overcomes the above-identified deficiency. Accordingly, this invention identifies several compounds that may enhance transdermal delivery of PDE-5 inhibitors, hence are useful for the development of an improved medicament for treating conditions or diseases mediated by PDE-5."

As a supplement to the background information on this patent application, NewsRx correspondents also obtained the inventors' summary information for this patent application: "The present disclosure is based on the finding that certain agent(s) is effective as an enhancer to promote transdermal delivery of a PDE-5 inhibitor, hence is useful as an agent or an adjuvant for developing a topical medicament for treating conditions or diseases mediated by PDE-5 such as erectile dysfunction or primary pulmonary hypertension.

"Accordingly, it is therefore an object of the present disclosure to provide an improved transdermal pharmaceutical composition with an enhanced transdermal absorption
rate of a PDE-5 inhibitor. According to embodiments of the present disclosure, the improved composition includes a phosphodiesterase type-5 (PDE-5) inhibitor or a pharmaceutically acceptable salt thereof, and a pharmaceutically acceptable excipient; and the improvement of the composition lies in having an enhancer of this invention, wherein the PDE-5 inhibitor and the enhancer are present in a ratio from about 20:1 to 2:1 in the improved composition of this invention. In one preferred example, the PDE-5 and the enhancer are present in a ratio of about 5:1 in the improved transdermal pharmaceutical composition.

"According to embodiments of the present disclosure, the enhancer is selected from the group consisting of cocamidopropyl betaine, sodium lauroamphoacetate, quaternium-60, isostearamidopropyl morpholine lactate, dipropylene glycol and a combination thereof. In one example, the enhancer is cocamidopropyl betaine. In another example, the enhancer is a mixture of cocamidopropyl betaine and sodium lauroamphoacetate. In still another example, the enhancer is a mixture of cocamidopropyl betaine, sodium lauroamphoacetate, and quaternium-60. In one preferred example, the enhancer is a mixture of cocamidopropyl betaine, sodium lauroamphoacetate, quaternium-60, and dipropylene glycol. The PDE-5 inhibitor is any of sildenafil, tadalafil or vardenafil. In one preferred example, the PDE-5 inhibitor is vardenafil, which is not in crystalline state.

"According to embodiments of the present disclosure, the improved pharmaceutical composition may be formulated into the form of a solution, a paste, a lotion, a cream, a gel, or a patch. In one embodiment, improved pharmaceutical composition is a gel. In another embodiment, the improved pharmaceutical composition is a skin patch.

"In another aspect, the present disclosure provides a method for enhancing transdermal delivery of a PDE-5 inhibitor in a subject. According to embodiments of the present disclosure, the method includes steps of administering to the subject the improved pharmaceutical composition of the present disclosure, which includes a PDE-5 inhibitor or a pharmaceutically acceptable salt thereof, a pharmaceutically acceptable excipient, and an enhancer of the present invention; wherein the PDE-5 inhibitor and the enhancer are present in a ratio from about 20:1 to 2:1 in the improved composition. In one preferred example, the PDE-5 and the enhancer are administered in a ratio of about 5:1.

"According to embodiments of the present disclosure, the enhancer of the present invention is any of cocamidopropyl betaine, sodium lauroamphoacetate, quaternium-60, isostearamidopropyl morpholine lactate, dipropylene glycol or a combination thereof. In one example, the enhancer is cocamidopropyl betaine. In another example, the enhancer is a mixture of cocamidopropyl betaine and sodium lauroamphoacetate. In still another example, the enhancer is a mixture of cocamidopropyl betaine, sodium lauroamphoacetate, and quaternium-60. In one preferred example, the enhancer is a mixture of cocamidopropyl betaine, sodium lauroamphoacetate, quaternium-60, and dipropylene glycol. The PDE-5 inhibitor is any of sildenafil, tadalafil or vardenafil. In one preferred example, the PDE-5 inhibitor is vardenafil, which is not in crystalline state.

"The improved method and/or pharmaceutical composition of the present disclosure can attain the same therapeutic benefits to the recipient thereof at a reduced level of PDE-5 inhibitor.

BRIEF DESCRIPTION OF THE DRAWINGS

"These and other features, aspects and advantages of the present invention will become better understood with reference to the following description, appended claims and the accompanying drawings, where:

"FIG. 1 illustrates the effects of formulations of Example 2.1 on in vitro transdermal
delivery of vardenafil in accordance with one embodiment of the present disclosure; and

"FIG. 2 illustrates the effects of the formulations of Example 2.1 and the skin patch of Example 2.2 on in vivo transdermal delivery of vardenafil in accordance with one embodiment of the present disclosure."

Keywords for this news article include: Biotechnology, Betaine, Patents, Sildenafil, Vardenafil, Impotence Agents, Phosphodiesterases, Drugs and Therapies, Transdermal Delivery, Cardiovascular Agents, Enzymes and Coenzymes, Surface-Active Agents, Genitourinary Tract Agents, Trimethyl Ammonium Compounds, Quaternary Ammonium Compounds.

Patents

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- From Washington, D.C., NewsRx journalists report that a patent application by the inventors STRADER, JAMES (AUSTIN, TX); PULITZER, JOVAN HUTTON (FRISCO, TX), filed on August 11, 2016, was made available online on December 29, 2016.

No assignee for this patent application has been made.

News editors obtained the following quote from the background information supplied by the inventors: "Immunotherapy basically involves a series of allergy shots given to reduce one's sensitivity to various allergens that may cause an allergic reaction. This immunotherapy can either be venom based or environmentally based. For venom based immunotherapy (VIT), treatments are available for allergies to stings such as honeybees, Yellowjackets, Hornets, paper wasps, fire ants and snakebites. For such things as insect stings, very small amount of the insect venom is injected under the skin in a dilute saline solution. This type of therapy is recommended for all patients who have experienced systemic reaction to insect sting and have specific IgE to venom allergens shown either my skin or blood test. Individuals with a history of a systemic reaction to an insect sting are at an increased risk of subsequent systemic sting reactions. VIT as compared to Environmental Immunotherapy is different than pollins and the such that one might be exposed to in the environment in that VIT is basically associated with allergens that are flown around inside a special injection device that, when counter, may threaten the lives of those who are sent to to it . . . . Insect venom allergy or snake venom. The primary offenders associated with VIT are prone primarily insects that sting rather than those that might or, as noted hereinabove, snakes. The insects that sting are typically members of the order of Hymenoptera of the class insect. This can include members of the Vespid family, Yellowjackets, yellow Hornets, white-faced Hornets and wasps. There also the
class of Apids, including honeybees and bumblebees. There's also the Formicid family that consists of fire ants and Harvester ants.

"To desensitize an individual against a particular venom, the process is to immunize the individual with small and graded doses of the venom. This is compared to the use of an anti-venom which is manufactured via a purified process in another animal such as a sheep. For example, the approved anti-venom for the pit viper (rattlesnake, copperhead and water moccasin) is based on a purified product made in sheep known as CroFab. These anti-venoms are typically administered through intravenous techniques. However, there are some antivenoms for such things as stonefish and redback spider that are administered intramuscularly. These antivenoms are injected after a bite, as they are designed to bind to and neutralize the venom, halting further damage, but do not reverse damage already done. This is compared to desensitizing an individual by small graded doses.

"In general, and antigen is any structural substance that serves as a target for the receptors of an adaptive immune response or, alternatively, and more simply stated, and antigen is any substance that causes an immune system to produce antibodies against it. An allergen is a type of antigen that produces an abnormally vigorous immune response in which the immune system fights off a perceived threat that would otherwise be harmless to the body. These reactions are termed allergies. Thus, by providing small graded doses of venom as the allergen, this would produce some type of immune response in the immune system that would generate anti-bodies to fight off the perceived threat. For small doses, the immune system can initially accommodate this and, as a doses increase, the immune system will continue to adapt and build up antibodies to this allergen, i.e., the venom of the particular insect or snake or other such. These allergens associated with the venom immunotherapy are specifically associated with allergens that originate from the internal organs of animals, insects or reptiles.

"Currently, most allergens associated with venom immunotherapy are not readily reimbursed when received from a pharmacist for the simple reason that the NDC code is not included in the database to which the pharmacist has access. Without an NDC code in the database, the pharmacist cannot access that information. By not being able to access information, the pharmacist cannot interface with a benefits provider for reimbursements nor can they have access to the Average Wholesale Price (AWP), which is the benchmark that has been used for many years for pricing and reimbursement of prescription drugs for both government and private payers. Initially, this AWP was intended to represent the average price that wholesalers used to sell medications to providers, such as physicians, pharmacies, and other customers. However, the AWP is not a true representation of actual market prices for either generic or brand drug products. AWP has often been compared to the 'list price' or 'sticker price', meaning it is an elevated drug price that is rarely what is actually paid. AWP is not a government-regulated figure, does not include buyer volume discounts or rebates often involved in prescription drug sales, and is subject to fraudulent manipulation by manufacturers or even wholesalers. As such, the AWP, while used throughout the industry, is a controversial pricing benchmark.

"The AWP may be determined by several different methods. The drug manufacturer may report the AWP to the individual publisher of drug pricing data, such as Medi-Span. The AWP may also be calculated by the publisher based upon a mark-up specified by the manufacturer that is applied to the wholesale acquisition cost (WAC) or direct price (DIRP). The WAC is the manufacturer's list price of the drug when sold to the wholesaler, while the DIRP is the manufacturer's list price when sold to non-wholesalers. Typically a 20% mark-up is applied to the manufacturer-supplied WAC or DIRP, which results in the AWP figure.

"The publishers then in turn sell these published AWPs to government, private insurance, and other buyers of prescription drugs, who use these data tables to determine
reimbursement and retail prices. Because AWP is a component of the formulas used to
determine reimbursement, elevated AWP numbers can drastically increase the dollar amount
that government, private insurance programs, and consumers with coinsurance must pay.

"Pharmacies typically buy drugs from a wholesaler and then sell them to the public. Many patients have coinsurance or copayments, where they only pay for a portion of their
prescription cost. The insurance company then pays the rest of the cost (the reimbursement) to
the pharmacy. Insurance companies include prescription benefit manager (PBM), health
maintenance organization (HMO) or government programs, such as Medicaid or Medicare Part
B or D. In addition, the pharmacy receives a dispensing fee for filling the prescription. Fees are,
for example, set between $3 to $5 per prescription, but may vary by state.

"Reimbursements are based on AWPs. However, pharmacies purchase drugs based
on the WAC. The difference between the WAC (what the pharmacy actually paid for the drug)
and the reimbursement from insurance (based on AWP) is known as the spread, and equates to
the profit that the pharmacy receives.

"Market pricing on brand drugs tend to be about 16.6 percent less than the AWP.
However, the relation of AWP to generic pricing is not clear. Older generics tend to have a large
spread between the AWP and WAC, which in turn gives a large spread, and higher profit
margins for the pharmacy or other provider of the drug. Many payers, such as PBMS or HMOs,
will determine a maximum allowable cost (MAC) pricing on generics to avoid being
overcharged. Newer generic products, compared to older generics, may not have as favorable of
a spread, thus the need for MAC.

"Collusion between AWP publishers and wholesalers to artificially inflate the AWP,
and in turn increase the spread, has led to court cases in the U.S. In these cases, it was alleged
that increasing the spread benefited the wholesaler because customers (pharmacies and large
institutions) were more likely to buy from them than a competing wholesaler where the spread
was not as desirable. The publisher of AWPs profited because pharmacies were more likely to
buy the pricing lists from the publisher that noted the higher AWPs used in calculating the
spread, than to buy them from other publishers with lower AWPs. Due to this pricing fraud,
many payers, including government payers, are no longer using AWP for pricing, and are
switching to other more transparent pricing benchmarks, such as WAC or AMP (average
manufacturers price). However, AWP may still be found in use in the U.S. because it has been
the standard for decades.

"However, in order for a pharmacist to access the AWP and to be able to interface
with benefits providers, the product associated with an NDC must be in the database. Currently,
nonvenoms are an item that does not exist in the database."

As a supplement to the background information on this patent application, NewsRx
correspondents also obtained the inventors' summary information for this patent application: "In
one aspect thereof, a method for adjudicating reimbursement for venom derived allergens
between a pharmacist and a reimbursing entity is provided. The method comprises obtaining at a
central control center National Drug Codes (NDC's) for a plurality of venom derived allergens at
a defined concentration level, each NDC uniquely identifying that particular allergen as to its
manufacture, the particular allergen, the packaging and the defined concentration level, and
further obtaining information as to a description of the particular venom derived allergen,
concentration level and manufacturer determining by the central control center an Average
Wholesale Price (AWP) for each of the venom derived allergens associated with each of the
NDC's, storing in a central control database the obtained NDC's in association with an
associated AWP and associated information for the venom derived allergen, which associated
information includes translation information to allow practitioners to determine from a desired
diluted level and number of doses of a desired NDC carrying venom derived antigen and a
known dilution procedure how to translate back to the amount of base concentration of the NDC
carrying venom derived antigen used to create the desired diluted level and number of doses,
accessing a third-party database accessible by a pharmacist and determining if any of the NDC's
in the central control database are contained within the third-party database and, if not,
transferring the associated NDC's not in the third-party database and that exist in the central
control database for each of the venom derived allergens to the third-party database in
association with the AWP and associated information for each of the venom derived allergens
for each of the NDC's, and uniquely associating each of the NDC's in the third-party database to
the central control center for adjudication information, and creating an adjudicating database at
the central control center having defined benefits associated with reimbursable entities for each
of the NDC's stored in the third-party database and in the central control database in association
with the translation information for each of the NDC-carrying venom derived allergens, wherein
a pharmacist can access this information by accessing a particular NDC in the third-party
database to obtain information regarding reimbursable benefits from the central control center
and enter the diluted level and number of doses and a claim with the central control center for
adjudication of the amount of base concentrate venom derived antigen used and wherein the
central control center is able to process any claim made by the pharmacist and reimburse the
pharmacist accordingly for the base concentrate venom derived antigen used to provide the
desired diluted level and number of doses of the desired NDC carrying venom derived antigen.

BRIEF DESCRIPTION OF THE DRAWINGS

"For a more complete understanding, reference is now made to the following
description taken in conjunction with the accompanying Drawings in which:
"FIG. 1 illustrates a general diagrammatic view of the overall interface of basic
databases;
"FIG. 1A illustrates an NDA code;
"FIG. 2 illustrates a diagrammatic view of a database that is populated by a central
control system;
"FIG. 3 illustrates a flow chart for the operation at the central control system for
receiving NDCs from the manufacturer;
"FIG. 4 illustrates a flow chart for the operation of populating third-party database by
the central control system;
"FIG. 5 illustrates a flow chart for the operation at the pharmaceutical location;
"FIG. 6 illustrates a flow chart for the overall generation of the AWP and the
interface with the benefit providers;
"FIG. 7 illustrates a diagrammatic view of flow beginning at the prick test and
following through to filling the prescription at the pharmacist location;
"FIG. 8 illustrates a flowchart for interfacing with database for accessing benefits by
the pharmacist;
"FIG. 9 illustrates a flowchart for the parsing operation at the database for parsing
non-NDC allergens to an NDC-bearing base concentrated allergen;
"FIG. 10 illustrates a diagrammatic view of a dilution sequence of diluting a
concentrated antigen extract;
"FIG. 11 illustrates a process flow for diluting an antigen extract;
"FIG. 12 illustrates a process flow for the overall distribution chain;
"FIG. 13 illustrates a process flow for multiple extracts; 
"FIG. 14 illustrates an alternate embodiment of FIG. 13; 
"FIG. 15 illustrates a flowchart for one example of processing a physician script; 
"FIG. 16 illustrates a diagrammatic view of a table in a relational database relating distributed doses back to NDC-bearing dose; 
"FIG. 16A illustrates a diagrammatic view of a table showing the dilution procedure; 
"FIG. 17 illustrates a second example of that illustrated in FIG. 15; 
"FIG. 18 illustrates a diagrammatic view of processing of a script received from a physician at a pharmacist to compound a patient-specific dosage; 
"FIG. 19 illustrates an alternate embodiment of that illustrated in FIG. 18; 
"FIG. 20A illustrates a diagrammatic view of a process of filling a script received from a position and FIG. 20B illustrates a table associated with such process; 
"FIG. 21 illustrates an overall process flow illustrating the prick test, the script flowing through to the final patient does; and 
"FIG. 22A illustrates a flowchart for parsing an antigen having a base dose with more than the prescribed antigens and FIG. 22B illustrates a table associated with the parsing operation."

Patents

Researchers Submit Patent Application, "Method of Regeneration of Beta-Cyclodextrin Based Adsorbent-Coated Silica with Ozone", for Approval (USPTO 20160367967)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- From Washington, D.C., NewsRx journalists report that a patent application by the inventor Suri, Rominder P.S. (Audubon, PA), filed on February 27, 2015, was made available online on December 29, 2016.

No assignee for this patent application has been made.

News editors obtained the following quote from the background information supplied by the inventors: "The most commonly used adsorbent for water contaminants is granular activated carbon (GAC). After it is used in a water treatment process, the GAC having adsorbed contaminants is either discarded or reactivated by heating the GAC to high temperatures. However, regenerating or reactivating GAC is an expensive process because of the energy costs involved in heating. Similarly, discarding used GAC is not desirable from an environmental perspective, and replacing the GAC that is discarded can be expensive. In addition, there are costs and liability associated with the transport of used GAC."

"The use of silica particles coated with (\beta.-cyclodextrin ((\beta.-CD) polymer for the removal of contaminants from water is described by Suri and Bhattarai (International Patent Pub. No. WO 2013/059285, which is hereby incorporated by reference in its entirety). In Suri and Bhattari, the adsorbent .beta.-CD-coated particles can be packed in a column or bed, wherein water is allowed to flow through the column so that contaminants are adsorbed onto the .beta.-CD adsorbent particles. Alternatively, .beta.-CD-coated particles can be mixed with stationary water, i.e., water in a tank wherein the mixture of water and .beta.-CD-coated particles is stirred to remove contaminants from the water. After the capacity of the .beta.-CD-coated particles to adsorb contaminants is reached, the particles can be regenerated by treating them with an organic solvent such as methanol (see Suri and Bhattari at para ). However, the use of organic solvent for regenerating .beta.-CD adsorbent creates the need for treating or disposing of the organic solvent after the regeneration process.

"Thus, there is a continuing need for a method of regenerating .beta.-CD adsorbent after the .beta.-CD has been used for decontaminating water. The present invention addresses this continuing need in the art."

As a supplement to the background information on this patent application, NewsRx correspondents also obtained the inventor's summary information for this patent application: "The present invention relates to systems and methods for regenerating .beta.-cyclodextrin (\beta.-CD) for reuse in a water treatment process. In one embodiment, the method of the present invention comprises the steps of: providing a .beta.-CD adsorbent, wherein at least a portion of the surface of said .beta.-CD adsorbent comprises one or more contaminants, and
removing at least a portion of said one or more contaminants from said .beta.-CD adsorbent by contacting said one or more contaminants with ozone gas. In another embodiment, the present invention is a method for regenerating .beta.-cyclodextrin (.beta.-CD) contained in a water treatment column for reuse in a water treatment process, comprising the steps of: providing a column having a compartment and an inlet, wherein said compartment contains a plurality of .beta.-CD adsorbent particles, and wherein at least a portion of the surface of the plurality of particles comprises one or more contaminants; and adding ozone gas through said column inlet into said compartment, wherein said ozone gas contacts the surface of the plurality of .beta.-CD adsorbent particles in said compartment, thereby removing at least a portion of said one or more contaminants from said .beta.-CD adsorbent particles. In yet another embodiment, the present invention is a method for regenerating .beta.-cyclo dextrin (.beta.-CD) contained in a water treatment vessel, comprising the steps of: providing a water treatment vessel containing water and a plurality of .beta.-CD adsorbent particles, wherein said .beta.-CD adsorbent particles comprise one or more contaminants; and adding ozone gas to said vessel, wherein said ozone gas contacts the surface of the .beta.-CD adsorbent particles thereby removing at least a portion of said one or more contaminants from said .beta.-CD adsorbent particles.

"In various embodiments, the .beta.-CD adsorbent can be any adsorbent material comprising .beta.-CD. In one embodiment, the .beta.-CD adsorbent is a silica particle coated with .beta.-CD polymer.

"In various embodiments, the one or more contaminant adsorbed onto the .beta.-CD adsorbent can be any type of organic compound. In one embodiment, the one or more contaminants is a phenol, for example bisphenol A (BPA). In one embodiment, the one or more contaminants is a steroid hormone, for example an estrogen, a progestogen, or a testosterone. In one embodiment, the steroid hormone is selected from the group consisting of 17 .beta. estradiol 17.alpha.-ethynylestradiol, estriol, 17.alpha.-estradiol, trimegestone, estrone, 17.alpha.-dihydroequilin, medrogestone, progesterone, gestodone, norgestrel, equilin, desogestrel, and etonorgestrel. In one embodiment, the one or more contaminants is a perfluoro compound. In one embodiment, the perfluoro compound is selected from the group consisting of tridecafluorononanoic acid, perfluoroheptanoic acid, undecafluorohexanoic acid, perfluorodecanoic acid, heptafluorooctane salt and perfluorooctanoic acid (PFOA).

"The systems and methods of the present invention can regenerate the adsorbent capacity of a .beta.-CD adsorbent to any capacity that would be suitable for reuse in a water treatment process. In one embodiment, at least 50% of the adsorbent capacity of the .beta.-CD adsorbent is regenerated after contacting said contaminants with ozone gas. In one embodiment, at least 50% of the surface area of the .beta.-CD adsorbent is regenerated, i.e., free of contaminants, after contacting said contaminants with ozone gas.

BRIEF DESCRIPTION OF THE DRAWINGS

"The following detailed description of preferred embodiments of the invention will be better understood when read in conjunction with the appended drawings. For the purpose of illustrating the invention, there are shown in the drawings embodiments which are presently preferred. It should be understood, however, that the invention is not limited to the precise arrangements and instrumentalities of the embodiments shown in the drawings.

"FIG. 1, comprising FIG. 1A and FIG. 1B, is a set of schematic diagrams of an exemplary embodiment of a batch water treatment system during water treatment (FIG. 1A) and during regeneration of .beta.-CD (FIG. 1B).

"FIG. 2 is a set of schematic diagrams of an exemplary embodiment of a continuous water treatment system during both water treatment operation and regeneration of .beta.-CD.
"FIG. 3 is a graph showing data for the regeneration of β-CD coated silica with ozonation for the removal of BPA in triplicates [initial conc: 200 m/L; adsorbent dosage: 1.0 g/L; intial pH: 6.2-7.1; Ozonation at 1 wt % and 20 L/hr for 2 hr].

"FIG. 4 is a graph showing data for the regeneration of β-CD coated silica with ozonation for the removal of 17β estradiol in triplicates [initial conc: 200 m/L; adsorbent dosage: 1.0 g/L; intial pH: 6.3-7.0; Ozonation at 1 wt % and 20 L/hr for 2 hr]."

Keywords for this news article include: Ozone, Patents, Chemistry, Gonadal Hormones, Estradiol Congeners.

Patents

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- From Washington, D.C., NewsRx journalists report that a patent application by the inventors Marshall, Aaron (Winnipeg, CA); Hou, Sen (Winnipeg, CA), filed on April 27, 2016, was made available online on December 29, 2016.

No assignee for this patent application has been made.

News editors obtained the following quote from the background information supplied by the inventors: "IgA nephropathy (IgAN), also known as Berger disease, is the most common cause of chronic glomerulonephritis and leads to end stage kidney failure in about 25% of cases. Twenty to forty percent of IgAN patients receiving kidney transplants suffer disease recurrence within 5 years of transplant. The onset of IgAN has been associated with upper respiratory tract infections that trigger the mucosal immune system. As a result of hyper-reactivity of the mucosal immune system, B cells produce increased amounts of IgA leading to IgA deposition in kidney glomeruli. IgA deposition leads to glomerular inflammation, resulting in kidney dysfunction, hypertension and slow progression towards kidney failure.

"Current treatments for IgAN are aimed at slowing kidney damage and include antihypertensives to control blood pressure and steroid treatment to reduce inflammation. Long term dialysis and kidney transplantation are used to treat end stage kidney failure but have a large negative impact on patient quality of life. Currently, no specific treatment is available to correct hyper-active mucosal immune responses or reduce IgA levels.

"Research into pathological mechanisms and new treatments for IgAN have been hampered by lack of appropriate animal models. Currently reported mouse models for IgAN include a multigenic outbred model with variable disease progression (ddY mouse), a single gene knockout that affects IgA deposition but not IgA production (uteroglobulin knockout), and a recently reported mouse transgenic for a B cell activating factor (BAFF transgenic). None of
these models selectively impact on IgA production and have to date not been widely adopted for IgAN studies.

"IgAN is estimated to affect over 60,000 people in the US, and several fold higher incidence of IgAN is reported among Asian populations. IgAN is incurable and the current limited treatment options include management of hypertension and administering non-specific anti-inflammatories in order to delay the need for dialysis or transplantation. No targeted therapies for reducing IgA production are available."

As a supplement to the background information on this patent application, NewsRx correspondents also obtained the inventors' summary information for this patent application: "The invention relates to the discovery and characterization of polypeptides that play a role in the production of IgA, and to the generation of an animal model that exhibits IgA nephropathy. The compositions and methods embodied in the present invention are particularly useful for drug screening and/or treatment of disorders that involve IgA.

"Provided herein are uses of an FDC-SP polypeptide and a pharmaceutically acceptable carrier. In one embodiment, the use is in the manufacture of a medicament for treating an IgA mediated condition. In one embodiment, the use is for treating an IgA mediated condition. An example of such a condition includes a glomerulonephritis, such as IgA nephropathy and Henoch-Schonlein purpura. Another example of such a condition includes IgA pemphigus. In one embodiment, the use is in the manufacture of a medicament for decreasing IgA concentration. In one embodiment, the use is for decreasing IgA concentration. The FDC-SP polypeptide may include an amino acid sequence X₁X₂X₃PWX₄ (SEQ ID NO:1), wherein X₁ and X₂ are any amino acid, X₃ is Y, F, or N, and X₄ is Y or F, and wherein the amino acid sequence of the isolated polypeptide has at least 90% amino acid similarity with SEQ ID NO:2 or SEQ ID NO:4. The FDC-SP polypeptide may include an amino acid sequence X₁X₂X₃PWX₄ (SEQ ID NO:1), wherein X₁ and X₂ are any amino acid, X₃ is Y, F, or N, and X₄ is Y or F, and wherein the amino acid sequence of the isolated polypeptide has at least 90% amino acid similarity with a subset of consecutive amino acids chosen from SEQ ID NO:2 or 4.

"Also provided herein are methods of using an FDC-SP polypeptide. In one embodiment, a method includes altering IgA concentration in a subject by administering to the subject in need thereof an effective amount of an FDC-SP polypeptide, wherein the FDC-SP polypeptide results in a decreased IgA level in the subject compared to the subject before the administration. The IgA level may be decreased, for instance, in serum, in bronchoalveolar lavage fluid, in saliva, or a combination thereof. The method may further include identifying a subject having or at risk of an IgA mediated condition. The decrease may be a decrease of at least 10%.

"The FDC-SP polypeptide may include an amino acid sequence X₁X₂X₃PWX₄ (SEQ ID NO:1), wherein X₁ and X₂ are any amino acid, X₃ is Y, F, or N, and X₄ is Y or F, and wherein the amino acid sequence of the isolated polypeptide has at least 90% amino acid similarity with SEQ ID NO:2 or SEQ ID NO:4. The FDC-SP polypeptide may include an amino acid sequence X₁X₂X₃PWX₄ (SEQ ID NO:1), wherein X₁ and X₂ are any amino acid, X₃ is Y, F, or N, and X₄ is Y or F, and wherein the amino acid sequence of the isolated polypeptide has at least 90% amino acid similarity with a subset of consecutive amino acids chosen from SEQ ID NO:2 or 4.

"In one embodiment, a method includes treating a subject by administering to the subject an effective amount of a FDC-SP polypeptide, wherein the subject has signs of a disorder that includes excessive IgA production. An example of such a disorder includes a
glomerulonephritis, such as IgA nephropathy and Henoch-Schonlein purpura. Another example of such a disorder includes IgA pemphigus.

"Provided herein is an animal that has decreased expression of an endogenous FDC-SP coding sequence, and which develops pathophysiological features of IgA nephropathy selected from IgA deposition in kidneys, mesangial hyperproliferation, and polypeptide deposition in glomeruli. Also provided herein is an animal that has decreased expression of an endogenous FDC-SP coding sequence, wherein the animal has at least one of the following: increased IgA in serum, saliva, bronchoalveolar lavage fluid, or a combination thereof; increased IgA expressing B lymphocytes in circulation, lymphoid tissue, or a combination thereof; or increased IgA production in vitro by isolated B lymphocytes; wherein the increase is compared to a control mouse. In one embodiment, the animal may have a heterozygous disruption of an endogenous FDC-SP coding sequence. In one embodiment, the animal may have a homozygous disruption of an endogenous FDC-SP coding sequence. In one embodiment, the animal is not a human. In one embodiment, the animal is a mouse.

"Also provided herein is a cell from the animal, wherein the cell has decreased expression of an endogenous FDC-SP coding sequence. Examples of such cells include, but are not limited to, a follicular dendritic cell, a monocyte, or a macrophage. Also provided herein is a tissue from the animal. The tissue may be, but is not limited to, lymphoid tissue.

"Provided herein are methods for identifying a compound that decreases the concentration of IgA in an animal. In one embodiment, the method includes administering to an animal a compound, and measuring the concentration of IgA, wherein a decreased concentration of IgA in an animal administered the compound compared to the concentration of IgA before the administration indicates the compound decreases the concentration of IgA in an animal. The concentration of IgA may be decreased, for instance, in serum, saliva, bronchoalveolar lavage fluid, or a combination thereof. The concentration of IgA may be measured by determining the number of IgA expressing B lymphocytes in circulation, lymphoid tissue, or a combination thereof, of the animal. A decrease in the number of IgA expressing B lymphocytes indicates a decreased concentration of IgA in the animal.

"Provided herein are methods for identifying a compound that treats a condition associated with increased levels of IgA. In one embodiment, the method includes administering to an animal a compound, wherein the animal displays a sign of a condition associated with increased levels of IgA, and evaluating a sign of a condition associated with increased levels of IgA, wherein a decrease in the presence of a sign indicates treats a condition associated with increased levels of IgA. The sign may be selected from IgA deposition in kidneys, mesangial hyperproliferation, polypeptide deposition in glomeruli, proteinuria, or a combination thereof. The animal may include decreased expression of an FDC-SP polypeptide.

"Also provided herein are polypeptides. In one embodiment, a polypeptide has immuno-modulatory activity, and includes an amino acid sequence X.sub.1X.sub.2X.sub.3PWX.sub.4 (SEQ ID NO:1), wherein X.sub.1 and X.sub.2 are any amino acid, X.sub.3 is Y, F, or N, and X.sub.4 is Y or F, and wherein the isolated polypeptide either (1) comprises no greater than 40 amino acids, or (2) comprises greater than 45 amino acids. In one embodiment, a polypeptide has immuno-modulatory activity, and includes an amino acid sequence X.sub.1X.sub.2X.sub.3PWX.sub.4 (SEQ ID NO:1), wherein X.sub.1 and X.sub.2 are any amino acid, X.sub.3 is Y, F, or N, and X.sub.4 is Y or F, and wherein the amino acid sequence of the isolated polypeptide has at least 90% amino acid and no greater than 99% similarity with SEQ ID NO:2 or SEQ ID NO:4. In one embodiment, a polypeptide has immuno-modulatory activity, and includes an amino acid sequence X.sub.1X.sub.2X.sub.3PWX.sub.4 (SEQ ID NO:1), wherein X.sub.1 and X.sub.2 are any amino acid, X.sub.3 is Y, F, or N, and X.sub.4 is Y or F, and wherein the amino acid sequence of the isolated polypeptide has at least
90% similarity with a subset of consecutive amino acids chosen from SEQ ID NO:2 or 4.

"As used herein, the term 'polypeptide' refers broadly to a polymer of two or more amino acids joined together by peptide bonds. The term 'polypeptide' also includes molecules which contain more than one polypeptide joined by a disulfide bond, or complexes of polypeptides that are joined together, covalently or noncovalently, as multimers (e.g., dimers, tetramers). Thus, the terms peptide, oligopeptide, enzyme, and protein are all included within the definition of polypeptide and these terms are used interchangeably. It should be understood that these terms do not connote a specific length of a polymer of amino acids, nor are they intended to imply or distinguish whether the polypeptide is produced using recombinant techniques, chemical or enzymatic synthesis, or is naturally occurring. An 'isolated' polypeptide is one that has been removed from a cell. For instance, an isolated polypeptide is a polypeptide that has been removed from the cytoplasm a cell, and many of the polypeptides, nucleic acids, and other cellular material of its natural environment are no longer present. A 'purified' polypeptide is one that is at least 60% free, preferably at least 75% free, and most preferably at least 90% free from other components of a cell.

"As used herein, a polypeptide may be 'structurally similar' to a reference polypeptide if the amino acid sequence of the polypeptide possesses a specified amount of sequence similarity and/or sequence identity compared to the reference polypeptide. Thus, a polypeptide may be 'structurally similar' to a reference polypeptide if, compared to the reference polypeptide, it possesses a sufficient level of amino acid sequence identity, amino acid sequence similarity, or a combination thereof.

"As used herein, the term 'polynucleotide' refers to a polymeric form of nucleotides of any length, either ribonucleotides, deoxyribonucleotides, peptide nucleic acids, or a combination thereof, and includes both single-stranded molecules and double-stranded duplexes. A polynucleotide can be obtained directly from a natural source, or can be prepared with the aid of recombinant, enzymatic, or chemical techniques. A polynucleotide described herein may be isolated. An 'isolated' polynucleotide is one that has been removed from its natural environment. Polynucleotides that are produced by recombinant, enzymatic, or chemical techniques are considered to be isolated and purified by definition, since they were never present in a natural environment.

"A 'regulatory sequence' is a nucleotide sequence that regulates expression of a coding sequence to which it is operably linked. Nonlimiting examples of regulatory sequences include promoters, enhancers, transcription initiation sites, translation start sites, translation stop sites, transcription terminators, and poly(A) signals. The term 'operably linked' refers to a juxtaposition of components such that they are in a relationship permitting them to function in their intended manner. A regulatory sequence is 'operably linked' to a coding region when it is joined in such a way that expression of the coding region is achieved under conditions compatible with the regulatory sequence.

"The term 'complementary' refers to the ability of two single stranded polynucleotides to base pair with each other, where an adenine on one polynucleotide will base pair to a thymine or uracil on a second polynucleotide and a cytosine on one polynucleotide will base pair to a guanine on a second polynucleotide.

"Conditions that are 'suitable' for an event to occur, or 'suitable' conditions are conditions that do not prevent such events from occurring. Thus, these conditions permit, enhance, facilitate, and/or are conducive to the event.

"As used herein, an antibody that can 'specifically bind' a polypeptide is an antibody that interacts only with the epitope of the antigen that induced the synthesis of the antibody, or interacts with a structurally related epitope. An antibody that 'specifically binds' to an epitope
will, under the appropriate conditions, interact with the epitope even in the presence of a diversity of potential binding targets.

"As used herein, 'ex vivo' refers to a cell that has been removed from the body of an animal. Ex vivo cells include, for instance, primary cells (e.g., cells that have recently been removed from a subject and are capable of limited growth in tissue culture medium), and cultured cells (e.g., cells that are capable of long term culture in tissue culture medium).

"As used herein, 'B cell' refers to lymphocytes that are able to produce antibody that specifically bind an epitope of an antigen. Examples of B cells include plasma B cells, memory B cells, B-1 cells, B-2 cells, marginal zone B cells, and follicular B cells. A B cell may include surface antigens such as CD19, CD20, CD21, CD22, CD23, surface immunoglobulin, Ig-alpha (also known as CD79A), and Ig-beta (also known as CD79B).

"The term 'and/or' means one or all of the listed elements or a combination of any two or more of the listed elements.

"The words 'preferred' and 'preferably' refer to embodiments of the invention that may afford certain benefits, under certain circumstances. However, other embodiments may also be preferred, under the same or other circumstances. Furthermore, the recitation of one or more preferred embodiments does not imply that other embodiments are not useful, and is not intended to exclude other embodiments from the scope of the invention.

"The terms 'comprises' and variations thereof do not have a limiting meaning where these terms appear in the description and claims.

"Unless otherwise specified, 'a,' 'an,' 'the,' and 'at least one' are used interchangeably and mean one or more than one.

"Also herein, the recitations of numerical ranges by endpoints include all numbers subsumed within that range (e.g., 1 to 5 includes 1, 1.5, 2, 2.75, 3, 3.80, 4, 5, etc.).

"For any method disclosed herein that includes discrete steps, the steps may be conducted in any feasible order. And, as appropriate, any combination of two or more steps may be conducted simultaneously.

"The above summary of the present invention is not intended to describe each disclosed embodiment or every implementation of the present invention. The description that follows more particularly exemplifies illustrative embodiments. In several places throughout the application, guidance is provided through lists of examples, which examples can be used in various combinations. In each instance, the recited list serves only as a representative group and should not be interpreted as an exclusive list.

BRIEF DESCRIPTION OF THE FIGURES

"FIG. 1A shows amino acid sequence of a mouse FDC-SP polypeptide, mFDC-SP (SEQ ID NO:6), a rat FDC-SP polypeptide, rFDC-SP (SEQ ID NO:7), a human FDC-SP polypeptide, hFDC-SP (SEQ ID NO:8), and a chimpanzee FDC-SP polypeptide, cFDC-SP (SEQ ID NO:9). The site of cleavage of the secretion signal is shown by the arrow.

"FIG. 1B shows nucleotide sequence of human FDC-SP mRNA (SEQ ID NO:10).

"FIG. 2A shows schematic showing strategy for constructing a deletion within the mouse FDC-SP gene removing a coding region encoding an FDC-SP polypeptide (referred to as a knockout or KO below).

"FIG. 2B-01 through 2B-07 shows the nucleotide sequence (SEQ ID NO:14) of the gene targeting construct shown in FIG. 2A. The location and sequence of the primer SC3-416 (SEQ ID NO:11), and the location and reverse sequence of the primer SC3-412 (SEQ ID NO:12) and the primer 4R2 (SEQ ID NO:13) are shown. Also shown are the two LoxP sites.
"FIG. 3A. Saliva was collected from anesthetized 10-14 week old control CD1 mice (WT) or FDC-SP transgenic (TG) mice and then animals were sacrificed by cardiac puncture to collect blood. Bronchoalveolar lavage (BALF) fluid was collected by flushing lungs with 10 mL of PBS. Levels of IgA or IgM antibody isotypes were measured using specific ELISA assays.

"FIG. 4A. Saliva was collected from anesthetized 10-14 week old control C57BL6 mice (WT) or FDC-SP knockout (KO) mice generated using the targeting construct in FIG. 2. Animals were sacrificed by cardiac puncture to collect blood. Bronchoalveolar lavage (BALF) fluid was collected by flushing lungs with 10 mL of PBS. Levels of the indicated antibody isotypes were measured using specific ELISA assays.

"FIG. 5A. Mesenteric lymph node, cervical lymph node, spleen, and blood cells were collected from young adult FDC-SP KO mice and frequency of IgA+ B lymphocytes were measured by flow cytometry. Bottom panels represent results from additional flow cytometry analyses which indicate otherwise normal B cell subset composition in FDC-SP KO mice. Graphs represent mean and SEM of 4 mice per genotype. Cervical and mesenteric refer to lymph nodes. T1, transitional type 1, gated as B220+IgM+CD23-CD21- lymphocytes; T2, transitional type 2, gated as B220+IgM+CD23+CD21+ lymphocytes; MZ, marginal zone, gated as B220+IgM+CD23-CD21+ lymphocytes; FO, follicular or B2 cells, gated as B220+IgM+CD23+CD21- lymphocytes; pre, pre-B cells, gated as B220+IgM-CD43- lymphocytes; pro, pro-B, gated as B220+IgM-CD43+ lymphocytes; immature, immature B cells, gated as B220+IgM++CD43- lymphocytes; Mature, mature recirculating B cells, gated as B220++IgM+CD43- lymphocytes.

"FIG. 6A. B cells were purified from spleens of control (WT) or FDC-SP KO mice using negative selection with anti-CD43 coupled magnetic beads. Cells were cultured for 5 days with the indicated stimuli, supernatants were harvested and IgA production was assessed by ELISA assays.

"FIG. 7A. B cells were purified from spleens of control or FDC-SP TG mice using negative selection with anti-CD43 coupled magnetic beads. Cells were cultured for 5 days with the indicated stimuli, supernatants were harvested and IgA production was assessed by ELISA assays.

"FIG. 8A. B cells were purified from spleens of C57BL6 mice using negative selection with anti-CD43 coupled magnetic beads. Cells were cultured for 5 days with the indicated stimuli and the indicated percentage of a supernatant containing recombinant FDC-SP (FDC-SP SN) or a control supernatant (Control SN). The resulting levels of IgA production by the cultured cells were measured by ELISA assay.

"FIG. 9A. The indicated synthetic peptides P1-P3 corresponding to mouse FDC-SP were added at the indicated concentrations to cultures of mouse B cells stimulated to produce IgA (TGFb1+IL-5). The resulting levels of IgA or IgM production were assessed by ELISA assays of culture supernatants. Percentage of cultured cells expressing IgA was also determined by flow cytometry (middle graph). P1 corresponds to amino acids 18-33 of mFDC-SP, P2 corresponds to amino acids 35-65 of mFDC-SP, and P3 corresponds to amino acids 60-84 of FDC-SP. Note that peptide P1 had no effect. Control peptides C1 and C2 were scrambled versions of corresponding FDC-SP derived peptides. hFDC-SP, human FDC-SP; mFDC-SP, mouse FDC-SP; um, micromolar.

"FIG. 10A shows the effect of the indicated synthetic peptides on IgA or IgM production assessed by ELISA assays of culture supernatants collected after 5 days of culture. Control peptide C5 was a scrambled version of P8. hFDC-SP, human FDC-SP; mFDC-SP, mouse FDC-SP; um, micromolar. P5 corresponds to amino acids 46-59 of mFDC-SP, P7 corresponds to amino acids 68-84 of mFDC-SP, and P8 corresponds to amino acids 60-65 of..."
"FIG. 10B shows the effect of the indicated synthetic peptides on IgA or IgM production assessed by ELISA assays of culture supernatants collected after 7 days of culture. Control peptide C5 was a scrambled version of P8. hFDC-SP, human FDC-SP; mFDC-SP, mouse FDC-SP; um, micromolar. P5 corresponds to amino acids 46-59 of mFDC-SP, P7 corresponds to amino acids 68-84 of mFDC-SP, and P8 corresponds to amino acids 60-65 of FDC-SP.

"FIG. 11A. Urine or serum collected from mice greater than one year old were assessed for the indicated biomarkers of kidney dysfunction.

"FIG. 12A. Kidneys from FDC-SP KO mice were assessed for abnormal histology by staining sections of formalin-fixed kidney with H&E or PAS stain.

"FIG. 13A. Kidney cryosections stained with FITC-labeled anti-IgA."

Our reports deliver fact-based news of research and discoveries from around the world. Copyright 2017, NewsRx LLC

Kyoto University

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- From Washington, D.C., NewsRx journalists report that a patent application by the inventors KAMEI, Kenichiro (Kyoto-shi, JP); CHEN, Yong (Kyoto-shi, JP), filed on February 24, 2015, was made available online on December 29, 2016.

The patent's assignee is Kyoto University.

News editors obtained the following quote from the background information supplied by the inventors: "The function of a cell in vivo is regulated in the extracellular microenvironment. The extracellular microenvironment consists mainly of (i) soluble factors such as growth factors, vitamins, and gas molecules, (ii) insoluble factors such as the stiffness of extracellular matrix proteins, and (iii) cell-cell interaction. These factors regulate the function of a cell while being intricately and strictly regulated. More specifically, in order to freely regulate the function of a target cell, such as a human ES cell and a human iPS cell, it is indispensable to freely regulate this extracellular microenvironment.

"However, the regulation occurs in an extremely small environment on a micrometer scale, and the traditional experimental cell culture technique using a 2D environment in a culture dish or a plate cannot reproduce the small environment. Thus, there is a demand for a
technique for creating an experimental 3D cell culture environment, which has been difficult to realize.

"Traditional experimental human ES/iPS cell culture techniques have been performed in a 2D environment such as a culture dish (Non-patent Literature 1 and 2).

"However, cells are present in a 3D environment in ordinary circumstances, and cannot express the original function in the 2D environment. In tissue engineering using human ES/iPS cells as well, it is very important to arrange a 3D environment.

"Size is also a very important factor. Cells in vivo are regulated in a microenvironment on a micrometer scale, for example, by the concentration gradients of soluble factors and the solidity of the extracellular substrate. It has been difficult for traditional techniques to regulate these factors. As a matter of course, it has been almost impossible to exhaustively analyze these factors."

As a supplement to the background information on this patent application, NewsRx correspondents also obtained the inventors' summary information for this patent application:

"Technical Problem

"An object of the present invention is to provide a microfluidic device suitable for culturing cells in a 3D environment and a 3D microculture method that enables the regulation and the analysis of function of cells, in particular, pluripotent stem cells.

"Solution to Problem

"The present invention developed a novel 3D cell microculture device for human ES cells and human iPS cells by using a microfluidic device. This microfluidic device enables the culture of an extremely small amount of cells, and can easily establish a 3D culture.

"Traditional culture and experimental techniques for the human ES cells and human iPS cells are performed in a 2D environment using a culture dish or a plate. However, the cells in vivo are regulated in a 3D microenvironment, and cannot fulfill the original function in the 2D environment. Thus, there has been a demand for a technique for creating an experimental 3D cell culture environment, which has been difficult to create by traditional techniques.

"The present inventors have been engaged in the development of a cell culture assay using a microfluidic device. The present invention has enabled a 3D culture by creating a 3D-like microenvironment using a microfluidic device, and using a highly biocompatible hydrogel as a cell support carrier.

"The present invention is a novel technique that has solved the problems of the existing methods and techniques. The following describes the features of the present invention in a preferable embodiment.

"(1) Development of a 3D culture method for cells, particularly for pluripotent stem cells, such as human ES/iPS cells, using a microfluidic device. (2) Creation of a 3D environment in a human ES/iPS cell culture method using a hydrogel (3) Simplification of cell introduction into and extract from the microfluidic device and a decrease in damages to the cells by using a phase transition hydrogel

"Specifically, the present invention provides the following microfluidic device and 3D microculture method.

"Item 1.

"A microfluidic device comprising at least one cell culture chamber, the or each chamber being connected to at least two openings, the device being configured to supply at least one physiologically active substance from at least one of the openings to the or each cell culture chamber in such a manner as to form a concentration gradient or concentration gradients in the or each chamber when cells and a hydrogel are introduced into the or each chamber to culture
the cells in a 3D-gel medium.

"Item 2.
"The microfluidic device according to item 1, wherein the hydrogel is formed inside the or each cell culture chamber.

"Item 3.
"The microfluidic device according to item 1 or 2, wherein a channel or channels connecting the at least one of the openings to the or each cell culture chamber are narrower than the diameter of the or each chamber.

"Item 4.
"A 3D cell microculture method comprising the steps of introducing cells and a fluidized hydrogel into the or each cell culture chamber of the microfluidic device according to any one of items 1 to 3;
"converting the hydrogel into a gel; and
"supplying at least one physiologically active substance from the at least one of the openings in such a manner as to form a concentration gradient or concentration gradients inside the or each cell culture chamber to culture the cells in the presence of the at least one physiologically active substance.

"Item 5.
"The 3D cell microculture method according to item 4, wherein the cells are pluripotent stem cells.

"Item 6.
"The 3D cell microculture method according to item 4, wherein the cells are human pluripotent stem cells.

"Item 7.
"The 3D microculture method according to any one of items 4 to 6, wherein multiple physiologically active substances are supplied into the or each cell culture chamber in such a manner as to form concentration gradients.

"Advantageous Effects of Invention
"The present invention enables a 3D cell microculture of cells, including pluripotent stem cells such as ES cells and iPS cells, using a microfluidic device. This microfluidic device enables a cell culture using an extremely small amount of cells, and can also easily establish a 3D culture.

"Because the microfluidic device according to the present invention can supply many different physiologically active substances to a 3D gel while forming respective concentration gradients thereof, the device can exhaustively screen various physiologically active substances for their action on the differentiation and functional regulation of cells, particularly pluripotent stem cells.

"The present invention is characterized in that the invention has created an extracellular microenvironment, which so far has been impossible to create in vitro, by using a microfluidic device, and developed a device for evaluating the cell response to the extracellular microenvironment. Because the functions of mammal cells, including human pluripotent stem cells, are strictly regulated in vivo by the extracellular microenvironment, it has been essential for the advancement of tissue engineering, cell transplant therapy, or regenerative medicine to know the regulation mechanism. The present development has overcome this problem, and can greatly contribute to the commercial viability of mammal pluripotent stem cells including human pluripotent stem cells.
"The device developed by the present invention can also be applied to drug discovery screening. Traditional cell-using drug discovery screening involves cells cultured in a 2D environment on a plate. However, the functional expression of cells requires the creation of a 3D environment; i.e., the cell response to a medicinal substance as a matter of course differs between a 2D culture and a 3D culture. The present invention also successfully achieved high throughput with a 3D culture, thus enabling a 3D culture of cells including human pluripotent stem cells, and drug discovery screening using the 3D culture.

"This extracellular microenvironment is very important not only for human pluripotent stem cells but also for cancer stem cells.

"Although the extracellular microenvironment has been suggested to be involved in the formation of cancer stem cells, it has been difficult to conduct a study on cancer stem cells in vitro. The 3D culture method of the present invention is applicable to the research of cancer stem cells, and can greatly contribute to the development of a basic remedy for cancer.

"It is also an advantage of the present invention that the use of the microfluidic device can decrease the amount and cost of a single sample.

"The use of the microfluidic device of the present invention can make it possible to stimulate cells physically and chemically at the same time, and to evaluate the cell response to the stimulations.

"In a preferable embodiment of the present invention, the invention has already gained an edge over other research in the achievement of high throughput using a 3D culture of human pluripotent stem cells. This high throughput is also advantageous in that the inlets of the device are arranged in the positions so as to correspond to the wells of a conventional 96-well plate, enabling the use of conventionally used equipment, such as an autoinjector, without modification. This is also a feature of the invention that the use of the microfluidic device can reduce the amount and cost of a single sample. Whereas 100 to 200 μL of a sample is necessary per sample in the use of a conventional 96-well plate, the amount of sample required by the present invention is 10 μL, which reduces the amount of sample to 1/10, achieving commercial viability.

BRIEF DESCRIPTION OF DRAWINGS

"FIG. 1: A conceptual diagram of a 3D microenvironmental culture of human pluripotent stem cells in the present invention. A mixed liquid of a fluidized hydrogel and human pluripotent stem cells is introduced into a microfluidic device to perform a 3D culture. Physiologically active substances necessary for the culture, such as growth factors, diffuse across the hydrogel, and are thereby supplied to the cells. Factors necessary for differentiation can also be optionally introduced.

"FIG. 2: A temperature-sensitive phase transition hydrogel (Mebiol.RTM.) used in the present invention. Changing the temperature enables the introduction of cells into a gel and the collection of the cells from the gel.

"FIG. 3: An experiment operation procedure of the present invention. 1. Preparation of a microfluidic device (.μ.FD). 2. A typical 2D culture of human pluripotent stem cells. 3. The human pluripotent stem cells are collected by an enzyme treatment or a physical treatment, and mixed with the hydrogel. 4. The mixture solution containing the human pluripotent stem cells and the hydrogel is introduced into the .μ.FD, and the temperature is changed to solidify the hydrogel. 5. 3D culture. The medium is replaced as necessary.

"FIG. 4: The steps for preparing a microfluidic device. A desired design was drawn by using 3D-CAD, and a mold of the structure was printed by a 3D printer. It is also possible to prepare a mold by typical photolithography or by using an injection-molding mold for mass
production. A PDMS liquid material (a mixture of a base and a curing agent) was poured into
the mold to prepare a device made of PDMS with a .\mu.FD structure.

"FIG. 5: Examples of the microfluidic device for a 3D culture according to the
present invention. Left: there is one large opening for cell introduction and medium
replacement, and one small opening as an outlet, with the two large and small openings
connected through a cell culture chamber. A medium, growth factors, and the like are
introduced from the large opening to thereby form the concentration gradients. Right: two large
openings are connected to a cell culture chamber. It is possible to homogeneously culture cells
in the cell culture chamber.

"FIG. 6: High throughput screening (HTS) microfluidic device (.\mu.FD). The 3D
culture of the present invention is also applicable to HTS-.\mu.FD.

"FIG. 7: Liquid feeding with an autoinjector. In 96-well (left figure) and 384-well
(right figure) formats, the correspondence between the pipette tips and HTS-.\mu.FD was
confirmed.

"FIG. 8: A photograph of human pluripotent stem cells that were 3D-cultured in a
.\mu.FD, and the shape of the colonies formed of human pluripotent stem cells cultured by
different techniques. When cultured in a .\mu.FD or a suspension culture, the human pluripotent
stem cells formed spherical cell aggregates. The traditional 2D culture formed a single-layered
colony.

"FIG. 9: The confirmation of the expression of human pluripotent stem cell markers
(OCT4 and NANOG) by immunofluorescent staining. Both markers exhibited high levels of
expression in the human pluripotent stem cells cultured in a .\mu.FD.

"FIG. 10: The confirmation of the expression of human pluripotent stem cell markers
(SSEA4 and TRA-1-60) and a differentiation marker (SSEA1) by flow cytometry. A 3D culture
was performed by using three gels with different degrees of solidity (Soft-HG, Mid-HG, and
Hard-HG). In every environment, the stem cell markers exhibited high levels of expression, and
the differentiation marker did not exhibit the expression.

"FIG. 11: The confirmation of the expression of human pluripotent stem cell markers
(SOX2, NANOG, and POU5F1 (OCT4)) by quantitative PCR. In every 3D culture (HG), the
stem cell markers exhibited high levels of expression as in the typical 2D culture (matrigel MG).

"FIG. 12: The 'solidity' of the 3D culture environment in a .\mu.FD can be changed by
the gel concentration. FIG. 12 shows the sizes of human pluripotent stem cell spheres in gels
with different degrees of solidity: too soft (45 mg mL.sup.-1), soft (61 mg mL.sup.-1), medium
(75 mg mL.sup.-1), and hard (91 mg mL.sup.-1). Although the spheres in the too soft hydrogel
can grow, the too soft gel cannot retain the cells.

"FIG. 13: High throughput screening (HTS) microfluidic device (.\mu.FD). As shown
in the photograph, screening using a 3D culture is possible. Cell-cycle analysis. Fewer G2/M
phase cells were present than those in the cells in a suspension culture.

"FIG. 14: The evaluation of cell activity (ATP) using a firefly luciferase. In every
condition, substantially the same ATP activity was confirmed with no damage to the cells.

"FIG. 15: The measurement of growth factor diffusion in a .\mu.FD/hydrogel. The
diffusion of bFGF (molecular weight: 17 kDa) and transferrin (molecular weight: 80 kDa) in
gels with different degrees of solidity was evaluated. Each factor was fluorescently labeled.
Factors with a smaller molecular weight rapidly diffused.

"FIG. 16: The diffusion of fluorescently labeled dextran in a .\mu.FD+hydrogel (Soft-
HG 61 mg mL.sup.-1). Fluorescently labeled dextran of different molecular weight was
prepared, and the way the dextran diffuses was observed with a fluorescence microscope. Larger
molecules did not easily diffuse in a hydrogel.

"FIG. 17: The diffusion of fluorescently labeled dextran in a .mu.FD+hydrogel (Soft-HG 61 mg mL.sup.-1). Fluorescently labeled dextran of different molecular weight was prepared, and the way the dextran diffuses was observed with a fluorescence microscope. While the fluorescence intensity was measured, the diffusion of the molecules was quantified. The diffusion decreased in accordance with the molecular weight.

"FIG. 18: The diffusion of fluorescently labeled dextran in a .mu.FD+hydrogel (Soft-HG 61 mg mL.sup.1). Dextran with a small molecular weight (3 to 5 kDa) was able to rapidly diffuse in a soft gel due to the influence of the solidity of the gel (concentration). However, dextran with a large molecular weight (10 kDa or more) was little affected by the solidity of the gel.

"FIG. 19: Colony formation efficiency of human pluripotent stem cells depending on the growth factor concentration gradient in a .mu.FD/hydrogel. Colonies were efficiently formed near the inlet in which the concentration of the growth factor was high.

"FIG. 20: High throughput screening (HTS) microfluidic device (.mu.FD) and a conceptual diagram of the microfluidic part. Cells mixed with a hydrogel were introduced into the cell culture chambers. It is possible to form a concentration gradient of a cell stimulant by connecting the tank for the medium for cell maintenance and the tank for the cell stimulation solution to each cell culture chamber.

"FIG. 21: Drawings of the designs of the cell culture chamber in a microfluidic device. Multiple concentration gradients can be formed in a single cell culture chamber. Various stimuli can be applied depending on the design of the microfluidic device."

Patents

Researchers Submit Patent Application, "Non-Vented Vial Drug Delivery", for Approval (USPTO 20160367746)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- From Washington, D.C., NewsRx journalists report that a patent application by the inventor Beiriger, Michael James (Pittsburgh, PA), filed on June 19, 2015, was made available online on December 29, 2016.

No assignee for this patent application has been made.

News editors obtained the following quote from the background information supplied by the inventors: "During hemodialysis, impurities and toxins are removed from the
blood of a patient by drawing the blood out of the patient through a blood access site, typically via a catheter, and then passing the blood through an artificial kidney (often referred to as a 'dialyzer'). The artificial kidney includes microtubes that each separate a first conduit from a second conduit. Generally, a dialysis solution (often referred to as a 'dialysate') flows through the first conduit of the dialyzer while the patient's blood flows through the second conduits of the dialyzer, causing impurities and toxins to be transferred from the blood to the dialysate through the microtubes. The impurities and toxins can, for example, be removed from the blood by a diffusion process. After passing through the dialyzer, the purified blood is then returned to the patient.

"When kidney failure is diagnosed, patients are typically given medication to help control the symptoms and slow the progress of damage to the kidneys. Patients with chronic kidney failure generally take drugs, such as iron supplements, to control the balance of minerals in the body."

As a supplement to the background information on this patent application, NewsRx correspondents also obtained the inventor's summary information for this patent application: "In one aspect of the invention, a fluid line set includes a vial adapter having a base, a spike extending from a central region of the base, a sidewall extending from the base and substantially surrounding the spike, a fluid line having a first end connected to the vial adapter and a second end, and a cap removably attached to the second end of the fluid line such that the cap seals the second end of the fluid line. The base and the side wall at least partially define a cavity configured to receive a portion of a vial. The cap includes a deformable portion that at least partially defines a gas chamber. The cap is configured so that deformation of the deformable portion causes gas to be forced from the gas chamber to the vial adapter via the fluid line.

"In another aspect of the invention, a method includes causing gas to flow through a fluid line of a dialysis system until the gas enters a drug vial connected to a vial adapter assembly causing a pressure within the drug vial to increase, and clamping the fluid line after increasing the drug vial pressure.

"In yet another aspect of the invention, a dialysis system includes a dialysis machine including a blood pump and a drug pump, a blood line set including a blood line that can be operably connected to the blood pump and a drip chamber in fluid communication with the blood line, a fluid line set including a fluid line including a first end connected to a vial adapter and a second end, and a cap removably attached to the second end of the fluid line such that the cap seals the second end of the fluid line. The cap includes a deformable portion at least partially defining a gas chamber. The cap is configured so that deformation of the deformable portion causes gas to be forced from the gas chamber to the vial adapter via the fluid line.

"Implementations can include one or more of the following features.

"In some implementations, the cap further includes a one-way valve.

"In certain implementations, the one way valve is disposed between the second end of the fluid line and the gas chamber to prevent fluid from passing into the gas chamber from the fluid line.

"In some implementations, the chamber includes a volume of sterile gas.

"In certain implementations, the sterile gas is air.

"In some implementations, the volume of sterile gas includes less than 2 ml of sterile gas.

"In certain implementations, the volume of sterile gas includes 1 to 2 ml of sterile gas.

"In some implementations, the fluid line includes a first end connected to the vial
adapter and a second end and a cap removably attached to the second end of the fluid line such that the cap seals the second end of the fluid line. The cap includes a deformable portion at least partially defining a gas chamber. The cap is configured so that deformation of the deformable portion causes gas to be forced from the gas chamber to the vial adapter via the fluid line.

"In certain implementations, the method includes fluidly connecting a drug vial with the fluid line via the vial adapter assembly. The vial adapter assembly includes a vial adapter having a spike extending from a central region of a base.

"In some implementations, the drug vial includes an initial internal pressure equal to an ambient pressure.

"In certain implementations, the drug vial includes an initial gas volume of 0.3 ml to 2 ml.

"In some implementations, the gas flowing through the delivery line introduces gas into the drug vial.

"In certain implementations, the gas volume within the drug vial is 2 ml to 3 ml.

"In some implementations, the introduced gas within the drug vial increases a pressure within the drug vial.

"In certain implementations, the method further includes removing the cap from the second end of the fluid line.

"In some implementations, the method further includes connecting the second end of the fluid line to an extracorporeal blood circuit.

"In some implementations, the method further includes delivering drug from the drug vial to the extracorporeal blood circuit via the drug delivery line.

"In certain implementations, the cap further includes a one-way valve.

"In some implementations, the one-way valve is disposed between the second end of the fluid line and the gas chamber to prevent fluid from passing into the gas chamber from the fluid line.

"In certain implementations, the chamber includes a volume of sterile gas.

"In some implementations, the sterile gas is air.

"In certain implementations, the volume of sterile gas includes less than 2 ml of sterile gas.

"In some implementations, the volume of sterile gas includes 1 to 2 ml of sterile gas.

"In some implementations, the dialysis system further includes a drug vial connected to the vial adapter, such that deformation of the deformable portion introduces causes gas to be forced into the drug vial.

"In certain implementations, the drug vial includes an initial gas volume of 0.3 to 2 ml.

"In some implementations, the additional gas increases the gas volume to 1 to 3 ml.

"Implementations can include one or more of the following advantages.

"The drug line sets described herein are designed to be used in medical systems, such as hemodialysis systems. Introducing air into the drug vials via the drug line sets of such systems decreases the vacuum pressure within the drug vial, which helps to ensure that the vacuum pressure generated within the drug line set by a pump exceeds the competing vacuum within the drug vial. This additional air improves the process of priming the system by helping to ensure that the desired amount of drug can be withdrawn from the drug vial. In addition, introducing additional air into the drug vial can account for air volume variations between drug vials of different manufacturers or manufacturing lots, which helps to expand the compatibility
of the medical devices with a variety of drug vials without modifying any hardware components. Further, by introducing air into the drug vial via the drug delivery line set, both the drug delivery line and the additional air can be sterilized using a single sterilization process.

"Other aspects, features, and advantages will be apparent from the description and drawings, and from the claims.

DESCRIPTION OF DRAWINGS

"FIG. 1 is a front view of a hemodialysis machine including a drug delivery module mounted in a mid-section of the machine.

"FIG. 2 is an enlarged view of the midsection of the hemodialysis machine of FIG. 1.

"FIG. 3 is a perspective view of a drug delivery fluid line set including a vial spiking assembly and priming cap connected to a drug delivery line.

"FIG. 4A is a perspective view of the drug delivery line set including the priming cap in the unactuated state and an enlarged view of the priming cap in an unactuated state.

"FIG. 4B is a perspective view of the drug delivery line set including the priming cap in the actuated state and an enlarged view of the priming cap in an actuated state.

"FIG. 5 is an enlarged view of the drug delivery module of the hemodialysis machine of FIG. 1 isolated from the hemodialysis machine.

"FIG. 6 is a perspective view of the vial spiking assembly and a spike cover.

"FIG. 7 is a perspective view of the drug delivery line set partially loaded into the drug delivery module.

"FIG. 8 is a perspective view of the drug vial being loaded onto the vial adapter.

"FIG. 9 is a perspective view of the drug delivery line set being loaded into a peristaltic pump of the drug delivery module.

"FIG. 10 is an enlarged view of the midsection of the hemodialysis machine of FIG. 1 showing the drug delivery line set connected to the hemodialysis set prior to operating the pumps. Certain details of the hemodialysis machine have been omitted for simplicity.

"FIGS. 11A and 11B are a perspective views of an alternative priming cap in the form of a dropper."

Patents

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- From Washington, D.C., NewsRx journalists report that a patent
application by the inventors LEE, Ilsoon (Okemos, MI); YU, Jing (East Lansing, MI); SANYAL, Oishi (East Lansing, MI), filed on May 18, 2016, was made available online on December 29, 2016.

No assignee for this patent application has been made.

News editors obtained the following quote from the background information supplied by the inventors: "This section provides background information related to the present disclosure which is not necessarily prior art.

"Layer-by-layer (LbL) assembled PEMs have been considered as a versatile platform for surface modification. In 1990s, Gero Decher pioneered the LbL technique to build multilayers by dipping a positive-charged substrate into polyanion and polycation solutions alternately, resulting in PEMs with precise structure control in nanometer scale. (Decher G. Science, 1997, 277(5330): 1232-1237.) For conventional LbL process, the dipping time for polyanion and polycation solutions is around 10 minutes or more. Sufficient washing steps are also required. And, to achieve a proper thickness, 10 bilayers or more are always needed. Thus, slow processing becomes one of the major issues for the industrializing PEM products. The short-time LbL technique originally pioneered by Grunlan et al., (Hagen D A, Foster B, Stevens B, et al. ACS Macro Letters, 2014, 3(7): 663-666.) is an effective tool for fabricating porous PEM structures.

"The conventional LbL process is extremely time consuming and it takes several hours to fabricate a PEM film of desired thickness. Hence, although the process has been developed more than a decade ago, and extensive research, both in terms of fundamentals as well as applications have been carried out, this LbL process has not seen industrial acceptance.

"Multi-scale porous structures have been successfully built up either with a micro-sized porous structure on top of a nano-sized porous structure or the other way around. According to the previous studies about porous PEM films, either only one porous structure was developed in one sample (Hiller J A, et al., Nature Materials, 2002, 1(1): 59-63; Berg M C, et al., Biomacromolecules, 2006, 7(1): 357-364; Cho C, Zacharia N S. Langmuir, 2011, 28(1): 841-848), or with micro- and nano-structures on top of the surface randomly (Fu J, Ji J, Shen L, et al. Langmuir, 2008, 25(2): 672-675.)."

As a supplement to the background information on this patent application, NewsRx correspondents also obtained the inventors’ summary information for this patent application: "This section provides a general summary of the disclosure, and is not a comprehensive disclosure of its full scope or all of its features.

"Porous polyelectrolyte multilayer (PEM) films have been created with precise pore size control ranging from nano- to micro-scale. Layer-by-layer (LbL) technique has been applied for fabricating PEMs, and the porous treatment has been carried out under acidic condition.

"The primary purpose of our work aims at reducing the processing time of the process to fabricate porous PEM films without compromising on the quality of the prepared films. This will enable the tremendously versatile LbL coating process to be economically fabricated. Besides shortening the processing time, we also tried polyelectrolytes with high molecular weight. This enables a broader control of pore size. Multi-scale porous structures have been first developed in this work, with either micro-sized porous structure on top of nano-sized porous structure or the reverse.

"Porous polyelectrolyte multilayer (PEM) films have been fabricated via fast layer-by-layer (LbL) technique, followed by acidic treatment with pH varying from 1.8 to 2.4. In our approach, the dipping time has been shortened significantly. The dipping time can be as short as 10 seconds or can be extended to about 15 minutes. The film thickness can be tuned by manipulating dipping time, molecular weight, number of bilayers, etc.
In this work, we use Poly(acrylic acid) (PAA) as the polyanion, and Poly(allylamine hydrochloride)(PAH) as polycation. In order to achieve a broader control of pore size, PAA with high molecular weight (M_{sub.w}=225,000 \text{ g/mol}) has been tried. This high molecular weight PAA can form special microfibrous structure on the surface via LbL assembly with dipping time longer than 5 minutes. However, with 10 second dipping, the surface is flat and smooth, and after porous treatment with pH of 2.0, pore size of 20-50 nm can be obtained, which is much smaller than what has been reported in literatures. (Cho C, Zacharia N S. Langmuir, 2011, 28 (1): 841-848. Berg M C, et al., Biomacromolecules, 2006, 7(1): 357-364.)

In this invention, we can control the micro-sized and nano-sized porous regions. To fabricate multi-scale porous structure, we first make the bottom porous structure via LbL assembly followed by acid treatment and crosslink the structure. Then the top porous structure can be further built up through the same way. If the bottom porous structure is with a nano-sized structure, the top porous structure can be built up with no need to consider the molecular weight of polyelectrolytes. However, if the bottom has micro-sized porous structure, higher molecular weight of polyelectrolytes is required for the top porous structure since the polymer chain needs to be large enough to avoid filling into bottom pores.

This invention has potential for various applications, such as 1) membranes, 2) drug delivery, and 3) super hydrophobic coatings (i.e., self-cleaning). For drug delivery, the porous structure can be considered as a drug reservoir. This invention allows the design of certain porous structures to fulfill the release requirements, such as initial burst release, sustained release, or a combination of both. The release kinetics can be precisely controlled by tuning the porous structure. For membrane applications, these porous PEM structures can also be used to replace the porous polysulfone and polyamide layers of reverse osmosis (RO) membranes. In addition, micro- and nano-structured surface can be achieved with our approach, which can be further modified by fluorinated silane molecules to obtain super hydrophobic (self-cleaning) surfaces.

**DRAWINGS**

The drawings described herein are for illustrative purposes only of selected embodiments and not all possible implementations, and are not intended to limit the scope of the present disclosure.

Corresponding reference numerals indicate corresponding parts throughout the several views of the drawings.

"FIG. 1 illustrates polyelectrolytes used.
"FIG. 2 details the LbL process.
"FIG. 3 is a graph of thickness of PEM film formed as a function of dipping time.
"FIGS. 4-6 show micrographs of PEM films.
"FIG. 7 is a graph of roughness as a function of dipping time.
"FIGS. 8-12 show micrographs of PEM films.
"FIGS. 13 and 14 show graphs of film thickness as a function of dipping time, molecular weight of polyelectrolyte, and pH of porous treatment.
"FIGS. 15-17 show micrographs of PEM thin films.
"FIG. 18 shows XPS results from treated PEM films.
"FIG. 19 is a photo of a free-standing film prepared according to the described methods.
"FIGS. 20-23 show micrographs illustrating design of multiscale porous structures."
"FIG. 24 shows the effect of dipping time on (a) the thickness of PAH.sub.L/PAA.sub.L thin films before and after the post treatment and (b) the relative expansion of thickness and average surface pore size.

"In FIG. 25, FIGS. 25A and 25B, 25C and 25D, 25E and 25F, 25G and 25H, and 25I and 25J are the top-view and cross-sectional SEM images for porous (PAH.sub.L/PAA.sub.L).sub.20.5 films with dipping time of 10 s, 1 min, 5 min, 10 min and 15 min, respectively. The arrow in each cross-sectional image indicates the interface between the glass substrate and the deposited film.

"FIG. 26 shows (a) thickness of thin films before and after the post treatment (FIG. 26A) and (b) the relative expansion of thickness and average surface pore size for (PAH.sub.L/PAA.sub.L).sub.20.5, (PAH.sub.H/PAA.sub.L).sub.20.5, (PAH.sub.L/PAA.sub.H).sub.20.5, and (PAH.sub.H/PAA.sub.H).sub.20.5 (FIG. 26B). All the films were fabricated using dipping time of 10 s.

"In FIG. 27, FIGS. 27A and 27B, 27C and 27D, 27E and 27F, and 27G and 27H are the top-view and cross-sectional SEM images for porous (PAH.sub.L/PAA.sub.L).sub.20.5, (PAH.sub.H/PAA.sub.L).sub.20.5, (PAH.sub.L/PAA.sub.H).sub.20.5, and (PAH.sub.H/PAA.sub.H).sub.20.5 films, respectively. The arrow in each cross-sectional image indicates the interface between the glass substrate and the deposited film. All the films were fabricated using dipping time of 10 s.

"FIG. 28 shows SEM cross-sectional (FIG. 28A and FIG. 28B) and top view (FIG. 28C) images of multi-scale porous thin films with nano-sized porous film as the bottom and micro-sized porous film as the top. The arrow in FIG. 28A indicates the interface between the glass substrate and the deposited film. FIG. 28B is an enlarged image of the square area in FIG. 28A.

"FIG. 29 shows SEM cross-sectional (FIG. 29A and FIG. 29B) and top view (FIG. 29C) images of multi-scale porous thin films with micro-sized porous structure as the bottom and nano-sized porous structure as the top. The arrow in FIG. 29A indicates the interface between the glass substrate and the deposited film. FIG. 29B is an enlarged image of the square area in FIG. 29A.

"FIGS. 30A, 30B, 30C, 30D, and 30E show SEM images of the porous (PAH.sub.H/PAA.sub.L).sub.20.5 surfaces with dipping time of 10 s, 1 min, 5 min, 10 min and 15 min, respectively. (The porous induction was done at pH=2.0.)

"FIG. 31 shows the values of contact angle for porous (PAH.sub.L/PAA.sub.L).sub.20.5 and (PAH.sub.H/PAA.sub.L).sub.20.5 with different dipping time.

"FIG. 32 shows super hydrophilic and super hydrophobic surfaces achieved before and after CVD for porous PAH.sub.H/PAA.sub.L thin film with dipping time of 1 min and acidic treatment at pH=2.0.

"FIGS. 33A, 33B, 33C, 33D, and 33E show images of the (PAH.sub.L/PAA.sub.L).sub.20.5 surfaces with dipping time of 10 s, 1 min, 5 min, 10 min and 15 min, respectively.

"FIGS. 34A, 34B, 34C, 34D, and 34E show images of the (PAH.sub.L/PAA.sub.H).sub.20.5 surfaces with dipping time of 10 s, 1 min, 5 min, 10 min and 15 min, respectively.

"FIG. 35 shows the values of (FIG. 35A) roughness and (FIG. 35B) contact angle for (PAH.sub.L/PAA.sub.L).sub.20.5 and (PAH.sub.L/PAA.sub.H).sub.20.5 with different dipping time.
"FIGS. 36A, 36B, 36C, 36D, and 36E show SEM images of the porous (PAH._sub_.L/PAA._sub_.L).sub._20.5 surfaces with dipping time of 10 s, 1 min, 5 min, 10 min and 15 min, respectively. (The porous induction was done at pH of 2.0.)

"FIGS. 37A, 37B, 37C, 37D, and 37E show SEM images of the porous (PAH._sub_.H/PAA._sub_.L).sub._20.5 surfaces with dipping time of 10 s, 1 min, 5 min, 10 min and 15 min, respectively. (The porous induction was done at pH of 2.0.)

"FIG. 38 shows the values of (FIG. 38A) roughness and (FIG. 38B) contact angle for (PAH._sub_.L/PAA._sub_.L).sub._20.5 and (PAH._sub_.L/PAA._sub_.H).sub._20.5 with different dipping time. (The porous induction was done at pH of 2.0.)

"FIGS. 39A, 39B, 39C, and 39D show SEM images of the porous (PAH._sub_.H/PAA._sub_.L).sub._20.5 surfaces (dipping time of 1 min) with porous induction at pH 1.8, 2.0, 2.2 and 2.4, respectively."

Patents

Researchers Submit Patent Application, "Treatment of Dermatological Pathologies", for Approval (USPTO 20160368982)

2017 JAN 14 (NewsRx) -- By a News Reporter-Staff News Editor at Obesity, Fitness & Wellness Week -- From Washington, D.C., NewsRx journalists report that a patent application by the inventor Simard, John (Austin, TX), filed on August 31, 2016, was made available online on December 29, 2016.

No assignee for this patent application has been made.

News editors obtained the following quote from the background information supplied by the inventors: "Inflammatory skin disorders acne, rosacea, and psoriasis afflict many millions of people. While not usually lethal, these conditions can cause physical discomfort and affect emotional well-being. There are currently a large number of different treatments for inflammatory skin disorders including corticosteroids, vitamin D analogs, coal tar, ultraviolet light, retinoids, methotrexate, cyclosporine, hydroxyurea, antibiotics, and biologic agents such as TNFalpha inhibitors. While these therapies have proven useful for many patients, many cause undesirable side-effects and none are ideal for every situation."

As a supplement to the background information on this patent application, NewsRx correspondents also obtained the inventor's summary information for this patent application: "The invention is based on the discovery that a mAb that specifically binds IL-1.alpha. is useful for reducing skin inflammation as well as treating inflammatory skin diseases including psoriasis vulgaris and acne vulgaris. This discovery was surprising for a number of reasons including previous reports that IL-1.alpha. levels are reduced in psoriatic skin (e.g., Bonifati et al., J Biol Regul Homeost Agents. 1997 Oct.-Dec.; 11(4):133-6) and a report implicating anakinra (IL-1 receptor antagonist) as a causative agent in the development of psoriasis."
Accordingly, the invention features a method of reducing skin inflammation in a human subject. This method can include the step of administering to the subject a pharmaceutical composition including a pharmaceutically acceptable carrier and an amount of an agent that selectively binds IL-1\(\alpha\). effective to reduce skin inflammation in the subject. The agent can be an anti-IL-1\(\alpha\) antibody such as a monoclonal antibody (e.g., of the IgG1 isotype), a monoclonal antibody that includes a complementarity determining region of MABp1, or MABp1. The skin inflammation can be associated with acne vulgaris and/or psoriasis vulgaris.

For example, one aspect of the invention features a method of reducing skin inflammation in a human subject by administering to the subject a pharmaceutical composition including a pharmaceutically acceptable carrier and an amount of an anti-IL-1\(\alpha\) Ab (or other agent that specifically and/or selectively binds IL-1\(\alpha\).) effective to reduce a symptom of skin inflammation (e.g., redness, swelling, leukocyte infiltration, or lesion development) in the subject by at least about 10\% (e.g., at least 8, 9, 10, 15, 17, 20, 30, 40, 50, 60, 70, 80, 90, or 100\%) as measured by any standard dermatological test. The anti-IL-1\(\alpha\). Ab can be a mAb such as an IgG1. The anti-IL-1\(\alpha\). Ab can be the mAb designated as MABp1 or a mAb that includes one or more complementarity determining regions (CDRs) of MABp1. The skin inflammation can be associated with acne or psoriasis. The pharmaceutical composition can be administered to the subject by injection, subcutaneously, intravenously, intramuscularly, or intradermally. In the method, the dose can be at least 0.25 (e.g., at least 0.2, 0.5, 0.75, 1, 2, 3, 4, or 5) mg/ml.

In other aspects, the invention includes use of an agent that selectively binds IL-1\(\alpha\). to treat skin inflammation in the subject and a pharmaceutical composition for treating skin inflammation in the subject, the composition comprising an agent that selectively binds IL-1\(\alpha\). In the foregoing, the agent can be an anti-IL-1\(\alpha\). antibody such as a monoclonal antibody (e.g., of the IgG1 isotype), a monoclonal antibody that includes a complementarity determining region of MABp1, or MABp1; and the skin inflammation can be associated with acne vulgaris and/or psoriasis vulgaris.

Unless otherwise defined, all technical terms used herein have the same meaning as commonly understood by one of ordinary skill in the art to which this invention belongs. Commonly understood definitions of biological terms can be found in Rieger et al., Glossary of Genetics: Classical and Molecular, 5th edition, Springer-Verlag: New York, 1991; and Lewin, Genes V, Oxford University Press: New York, 1994. Commonly understood definitions of medical terms can be found in Stedman's Medical Dictionary, 27.sup.th Edition, Lippincott, Williams & Wilkins, 2000.

As used herein, an 'antibody' or 'Ab' is an immunoglobulin (Ig), a solution of identical or heterogeneous Igs, or a mixture of Igs. An 'Ab' can also refer to fragments and engineered versions of Igs such as Fab, F(ab'), and F(ab').sub.2 fragments; and scFv's, heteroconjugate Abs, and similar artificial molecules that employ Ig-derived CDRs to impart antigen specificity. A 'monoclonal antibody' or 'mAb' is an Ab expressed by one clonal B cell line or a population of Ab molecules that contains only one species of an antigen binding site capable of immunoreacting with a particular epitope of a particular antigen. A 'polyclonal Ab' is a mixture of heterogeneous Abs. Typically, a polyclonal Ab will include myriad different Ab molecules which bind a particular antigen with at least some of the different Abs immunoreacting with a different epitope of the antigen. As used herein, a polyclonal Ab can be a mixture of two or more mAbs.

An 'antigen-binding portion' of an Ab is contained within the variable region of the
Fab portion of an Ab and is the portion of the Ab that confers antigen specificity to the Ab (i.e., typically the three-dimensional pocket formed by the CDRs of the heavy and light chains of the Ab). A 'Fab portion' or 'Fab region' is the proteolytic fragment of a papain-digested Ig that contains the antigen-binding portion of that Ig. A 'non-Fab portion' is that portion of an Ab not within the Fab portion, e.g., an 'Fc portion' or 'Fc region.' A 'constant region' of an Ab is that portion of the Ab outside of the variable region. Generally encompassed within the constant region is the 'effector portion' of an Ab, which is the portion of an Ab that is responsible for binding other immune system components that facilitate the immune response. Thus, for example, the site on an Ab that binds complement components or Fc receptors (not via its antigen-binding portion) is an effector portion of that Ab.

"When referring to a protein molecule such as an Ab, 'purified' means separated from components that naturally accompany such molecules. Typically, an Ab or protein is purified when it is at least about 10% (e.g., 9%, 10%, 20%, 30%, 40%, 50%, 60%, 70%, 80%, 90%, 95%, 98%, 99%, 99.9%, and 100%), by weight, free from the non-Ab proteins or other naturally-occurring organic molecules with which it is naturally associated. Purity can be measured by any appropriate method, e.g., column chromatography, polyacrylamide gel electrophoresis, or HPLC analysis. A chemically-synthesized protein or other recombinant protein produced in a cell type other than the cell type in which it naturally occurs is 'purified.'

"By 'bind', 'binds', or 'reacts with' is meant that one molecule recognizes and adheres to a particular second molecule in a sample, but does not substantially recognize or adhere to other molecules in the sample. Generally, an Ab that 'specifically binds' another molecule has a K_{d} greater than about 10^{5}, 10^{6}, 10^{7}, 10^{8}, 10^{9}, 10^{10}, 10^{11}, or 10^{12} liters/mole for that other molecule. An Ab that 'selectively binds' a first molecule specifically binds the first molecule at a first epitope but does not specifically bind other molecules that do not have the first epitope. For example, an Ab which selectively binds IL-1 alpha specifically binds an epitope on IL-1 alpha but does not specifically bind IL-1beta (which does not have the epitope).

"A 'therapeutically effective amount' is an amount which is capable of producing a medically desirable effect in a treated animal or human (e.g., amelioration or prevention of a disease or symptom of a disease).

"Although methods and materials similar or equivalent to those described herein can be used in the practice or testing of the present invention, suitable methods and materials are described below. All applications and publications mentioned herein are incorporated by reference in their entirety. In the case of conflict, the present specification, including definitions will control. In addition, the particular embodiments discussed below are illustrative only and not intended to be limiting.

DETAILED DESCRIPTION

"The invention encompasses compositions and methods for reducing skin inflammation including ameliorating one or more symptoms of a dermatological pathology in a subject. The below described preferred embodiments illustrate adaptation of these compositions and methods. Nonetheless, from the description of these embodiments, other aspects of the invention can be made and/or practiced based on the description provided below.

"General Methodology

"Methods involving conventional immunological and molecular biological techniques are described herein. Immunological methods (for example, assays for detection and localization of antigen-Ab complexes, immunoprecipitation, immunoblotting, and the like) are generally known in the art and described in methodology treatises such as Current Protocols in
"Treatment of Skin Inflammation"

The compositions and methods described herein are useful for treating skin inflammation (e.g., associated with rosacea, eczema, psoriasis, xerosis, dermatitis, acne, pyoderma gangrenosum, urticaria, lichenoid disorders, bullous diseases such as bullous pemphigoid, cutaneous vasculitis, and granulomatous skin diseases) in a mammalian subject by administering to the subject a pharmaceutical composition including an amount of an anti-IL-1.alpha. Ab effective to improve at least one characteristic (e.g., reduction in the number or size of lesions, reduction of redness, and reduction in itchiness) of the inflammation in the subject. The mammalian subject might be any that suffers from skin inflammation including, human beings, dogs, cats, horses, cattle, sheep, goats, and pigs. Human subjects might be male, female, adults, children, seniors (65 and older), and those with other diseases. Particularly preferred subjects are those whose disease has progressed or failed to respond after treatment with other anti-inflammatory or anti-microbial agents such as retinoids, antibiotics, steroids or cytokine inhibitors such as TNFalpha inhibitors. Subjects who have developed a human anti-human antibody response due to prior administration of therapeutic antibodies are preferred when the anti-IL-1.alpha. Ab is a true human Ab (e.g., one that is naturally expressed in a human subject) such as MABp1. Any type of inflammatory skin disease susceptible to treatment with an anti-IL-1.alpha. Ab might be targeted. Anti-IL-1.alpha. Ab administration is thought to be particularly effective for treating acne vulgaris and psoriasis vulgaris.

"Antibodies and Other Agents that Target IL-1.alpha.

Any suitable type of Ab that specifically binds IL-1.alpha. and reduces a characteristic of skin inflammation and/or an inflammatory skin disease such as acne vulgaris or psoriasis vulgaris in a subject might be used in the invention. For example, the anti-IL-1.alpha. Ab used might be mAb, a polyclonal Ab, a mixture of mAbs, or an Ab fragment or engineered Ab-like molecule such as an scFv. The Ka of the Ab is preferably at least 1.times.10.sup.9 M.sup.-1 or greater (e.g., greater than 9.times.10.sup.10 M.sup.-1, 8.times.10.sup.10 M.sup.-1, 7.times.10.sup.10 M.sup.-1, 6.times.10.sup.10 M.sup.-1, 5.times.10.sup.10 M.sup.-1, 4.times.10.sup.10 M.sup.-1, 3.times.10.sup.10 M.sup.-1, 2.times.10.sup.10 M.sup.-1, or 1.times.10.sup.10 M.sup.-1). In a preferred embodiment, the invention utilizes a fully human mAb that includes (i) an antigen-binding variable region that exhibits very high binding affinity (e.g., at least nano or picomolar) for human IL-1.alpha. and (ii) a constant region. The human Ab is preferably an IgG1, although it might be of a different isotype such as IgM, IgA, or IgE, or subclass such as IgG2, IgG3, or IgG4. One example of a particularly useful mAb is MABp1, an IL-1.alpha.-specific IgG1 mAb described in U.S. patent application Ser. No. 12/455,458 filed on Jun. 1, 2009. Other useful mAbs are those that include at least one but preferably all the CDRs of MABp1.

"Because B lymphocytes which express Ig specific for human IL-1.alpha. occur
naturally in human beings, a presently preferred method for raising mAbs is to first isolate such a B lymphocyte from a subject and then immortalize it so that it can be continuously replicated in culture. Subjects lacking large numbers of naturally occurring B lymphocytes which express Ig specific for human IL-1.alpha. may be immunized with one or more human IL-1.alpha. antigens to increase the number of such B lymphocytes. Human mAbs are prepared by immortalizing a human Ab secreting cell (e.g., a human plasma cell). See, e.g., U.S. Pat. No. 4,634,664.

"In an exemplary method, one or more (e.g., 5, 10, 25, 50, 100, 1000, or more) human subjects are screened for the presence of such human IL-1-alpha-specific Ab in their blood. Those subjects that express the desired Ab can then be used as B lymphocyte donors. In one possible method, peripheral blood is obtained from a human donor that possesses B lymphocytes that express human IL-1.alpha.-specific Ab. Such B lymphocytes are then isolated from the blood sample, e.g., by cells sorting (e.g., fluorescence activated cell sorting, 'FACS'; or magnetic bead cell sorting) to select B lymphocytes expressing human IL-1.alpha.-specific Ig. These cells can then be immortalized by viral transformation (e.g., using EBV) or by fusion to another immortalized cell such as a human myeloma according to known techniques. The B lymphocytes within this population that express Ig specific for human IL-1.alpha. can then be isolated by limiting dilution methods (e.g., cells in wells of a microtiter plate that are positive for Ig specific for human IL-1.alpha. are selected and subcultured, and the process repeated until a desired clonal line can be isolated). See, e.g., Goding, MAbs: Principles and Practice, pp. 59-103, Academic Press, 1986. Those clonal cell lines that express Ig having at least nanomolar or picomolar binding affinities for human IL-1.alpha. are preferred. MAbs secreted by these clonal cell lines can be purified from the culture medium or a bodily fluid (e.g., ascites) by conventional Ig purification procedures such as salt cuts, size exclusion, ion exchange separation, and affinity chromatography.

"Although immortalized B lymphocytes might be used in in vitro cultures to directly produce mAbs, in certain cases it might be desirable to use heterologous expression systems to produce mAbs. See, e.g., the methods described in U.S. patent application Ser. No. 11/754,899. For example, the genes encoding an mAb specific for human IL-1.alpha. might be cloned and introduced into an expression vector (e.g., a plasmid-based expression vector) for expression in a heterologous host cell (e.g., CHO cells, COS cells, myeloma cells, and E. coli cells). Because Igs include heavy (H) and light (L) chains in an H\_sub.2L\_sub.2 configuration, the genes encoding each may be separately isolated and expressed in different vectors.

"Although generally less preferred due to the greater likelihood that a subject will develop an anti-Ab response, chimeric mAbs (e.g., 'humanized' mAbs), which are antigen-binding molecules having different portions derived from different animal species (e.g., variable region of a mouse Ig fused to the constant region of a human Ig), might be used in the invention. Such chimeric Abs can be prepared by methods known in the art. See, e.g., Morrison et al., Proc. Nat'l. Acad. Sci. USA, 81:6851, 1984; Neuberger et al., Nature, 312:604, 1984; Takeda et al., Nature, 314:452, 1984. Similarly, Abs can be humanized by methods known in the art. For example, mAbs with a desired binding specificity can be humanized by various vendors or as described in U.S. Pat. Nos. 5,693,762; 5,530,101; or 5,585,089.

nucleotide sequence encoding the Ab. In addition, modifications to nucleic acid sequences encoding mAbs might be altered (e.g., without changing the amino acid sequence of the mAb) for enhancing production of the mAb in certain expression systems (e.g., intron elimination and/or codon optimization for a given expression system). The mAbs described herein can also be modified by conjugation to another protein (e.g., another mAb) or non-protein molecule. For example, a mAb might be conjugated to a water soluble polymer such as polyethylene glycol or a carbon nanotube (See, e.g., Kam et al., Proc. Natl. Acad. Sci. USA 102: 11600-11605, 2005). See, U.S. patent application Ser. No. 11/754,899.

"Preferably, to ensure that high titers of human IL-1.alpha.-specific mAb can be administered to a subject with minimal adverse effects, the mAb compositions of the invention are at least 0.5, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 20, 25, 30, 35, 40, 45, 50, 60, 70, 80, 90, 95, 96, 97, 98, 99, 99.9 or more percent by weight pure (excluding any excipients). The mAb compositions of the invention might include only a single type of mAb (i.e., one produced from a single clonal B lymphocyte line) or might include a mixture of two or more (e.g., 2, 3, 4, 5, 6, 7, 8, 9, 10 or more) different types of mAbs.

"To modify or enhance their function, the human IL-1.alpha. mAbs might be conjugated with another molecule such as a cytotoxin. A human IL-1.alpha. specific mAb might be conjugated with one or more cytotoxins to more effectively kill cells expressing IL-1.alpha.. Cytotoxins for use in the invention can be any cytotoxic agent (e.g., molecule that can kill a cell after contacting the cell) that can be conjugated to a human IL-1.alpha. specific mAb. Examples of cytotoxins include, without limitation, radionuclides (e.g., .sup.35S, .sup.14C, .sup.32P, .sup.125I, .sup.131I, .sup.90Y, .sup.89Zr, .sup.201Tl, .sup.186Re, .sup.188Re, .sup.57Cu, .sup.213Bi, and .sup.211At), conjugated radionuclides, and chemotherapeutic agents. Further examples of cytotoxins include, but are not limited to, antimetabolites (e.g., 5-fluorouricil (5-FU), methotrexate (MTX), fludarabine, etc.), anti-microtubule agents (e.g., vincristine, vinblastine, colchicine, taxanes (such as paclitaxel and docetaxel), etc.), alkylating agents (e.g., cyclophosphamide, melphalan, bischloroethylnitrosurea (BCNU), etc.), platinum agents (e.g., cisplatin (also termed cDDP), carboplatin, oxaliplatin, JM-216, CI-973, etc.), anthracyclines (e.g., doxorubicin, daunorubicin, etc.), antibiotic agents (e.g., mitomycin-C), topoisomerase inhibitors (e.g., etoposide, tenoposide, and camptothecins), or other cytotoxic agents such as ricin, diptheria toxin (DT), Pseudomonas exotoxin (PE) A, PE40, abrin, saporin, pokeweed viral protein, ethidium bromide, glucocorticoid, anthrax toxin and others. See, e.g., U.S. Pat. No. 5,932,188.

"While the IL-1.alpha. specific Abs described above are preferred for use in the invention, in some cases, other agents that specifically target IL-1.alpha. might be used so long as their administration leads to improvement of a characteristic of an inflammatory skin disease. These other agents might include vaccines that cause the production of anti-IL-1.alpha. Abs, proteins or peptides that bind IL-1.alpha., and small organic molecules which specifically target IL-1.alpha.. Those that do not specifically bind other agents that specifically target IL-1.beta. are preferred.

"Pharmaceutical Compositions and Methods

"The anti-IL-1.alpha. Ab compositions (and other agents that specifically target IL-1.alpha.) may be administered to animals or humans in pharmaceutically acceptable carriers (e.g., sterile saline), that are selected on the basis of mode and route of administration and standard pharmaceutical practice. A list of pharmaceutically acceptable carriers, as well as pharmaceutical formulations, can be found in Remington’s Pharmaceutical Sciences, a standard text in this field, and in USP/NF. Other substances may be added to the compositions and other steps taken to stabilize and/or preserve the compositions, and/or to facilitate their administration.
to a subject.

"For example, the Ab compositions might be lyophilized (see Draber et al., J. Immunol. Methods. 181:37, 1995; and PCT/US90/01383); dissolved in a solution including sodium and chloride ions; dissolved in a solution including one or more stabilizing agents such as albumin, glucose, maltose, sucrose, sorbitol, polyethylene glycol, and glycine; filtered (e.g., using a 0.45 and/or 0.2 micron filter); contacted with beta-propiolactone; and/or dissolved in a solution including a microbicide (e.g., a detergent, an organic solvent, and a mixture of a detergent and organic solvent.

"The Ab compositions may be administered to animals or humans by any suitable technique. Typically, such administration will be parenteral (e.g., intravenous, subcutaneous, intramuscular, or intraperitoneal introduction). The compositions may also be administered directly to the target site (e.g., the skin) by, for example, topical application. Other methods of delivery, e.g., liposomal delivery or diffusion from a device impregnated with the composition, are known in the art. The composition may be administered in a single bolus, multiple injections, or by continuous infusion (e.g., intravenously or by peritoneal dialysis).

"A therapeutically effective amount is an amount which is capable of producing a medically desirable result in a treated animal or human. An effective amount of anti-IL-1.alpha. Ab compositions is an amount which shows clinical efficacy in patients as measured by the improvement in one or more symptoms of skin inflammation. As is well known in the medical arts, dosage for any one animal or human depends on many factors, including the subject's size, body surface area, age, the particular composition to be administered, sex, time and route of administration, general health, and other drugs being administered concurrently. Preferred doses range from about 0.1 to 5 (e.g., 0.05, 0.1, 0.15, 0.2, 0.3, 0.4, 0.5, 1, 2, 3, 4, 5, or 6) mg/kg body weight. In some cases a single dose is effective at resolving an episode of skin inflammation. In other cases, doses may be given repeatedly, e.g., semi-weekly, weekly, bi-weekly, tri-weekly, semi-monthly, once every three weeks, monthly, bi-monthly, or as needed (if skin inflammation recurs)."
